It may be said that the policy of taking over the coal mines, and of controlling the distribution and prices of coal, has been justified by its results. In 1913 there were 1,110,884 men employed in and about British coal mines, and of this number 316,000 have joined the army. Other labor has been drafted in, so that the employees during 1917 numbered approximately 987,000, a reduction of only 133,000 men. Still, the loss of the young, vigorous and trained miners was severly felt, and it is a matter for satisfaction that the output for coal during the years 1915, 1916 and 1917 should have been so well maintained.

The present output is naturally a good deal less than it was before the war—this was inevitable—but, after taking account of the big reduction in coal for export, it may be said that the amount available for inland consumption, the admiralty, and for ships' bunkers, is almost as large now as it was in 1913. The admiralty's requirements, of course, expanded enormously, and the supplies available for inland consumers (other than direct war industries) have had to be cut down and the strictest economy insisted upon.

Everything possible is being done to secure economy. Electric supply undertakings have been urged to interconnect wherever this can be done at a small expenditure of materials and labor; representations have been made to the Home Office in order to secure lighting restrictions and the early closing of shops; and the need for economy has been brought prominently before the public by appeals to both industrial and domestic consumers. The London district has been definitely rationed. The whole country will undoubtedly be rationed before the close of 1918.

The net result is shown in the following table, which gives the comparative figures of coal production and consumption for the years 1913, 1916 and 1917:

	1913 Million Tons	1916 Million Tons	1917 (Partly Estimated) Million Tons
Coal output	287	256	247 5
Export	77	42	38
Balance available for inland, admiralty and bunkers	210	214	207
Stocks at pithead on hand at close of year	2	2	4 5

It will be seen that the coal available for inland, admiralty and bunkers shows only a slight falling off as compared with the pre-war year 1913, while stocks on hand at the end of the last year show an increase. This increase, is however, largely made up of small coal, which cannot now be exported.

The exports have fallen off largely in 1917, owing to the shortage of shipping, and the decrease in exports at the end of 1917 as compared with the end of 1916 was approximately 3,000,000 tons per annum.

Ohio Production in 1917

The Industrial Commission of Ohio, Department of Investigation and Statistics, Columbus, Ohio, has tabulated the coal production for the year ending Dec. 31, 1917, and has classified the data according to method of production by counties, as follows:

County	Tons — Pick-Mined	Machine-Mined	Stripped	Total
Athens	356,973	5,956,446	200	6,313,619
Belmont	516,709	10,639,917	.....	11,156,626
Carroll	165,228	320,508	1,356	487,092

MOVIE, BARBER SHOP AND COMMISSARY OF THE SOUTHERN MINING CO., BALKAN, KENTUCKY

GENERAL VIEW OF CARBONADO

Coal Mining in Carbonado, Washington*

By F. G. JARRETT
Superintendent of Mines, Eska Creek, Alaska.

SYNOPSIS — *The mines here described lie in an extremely rough country, and many difficulties not found in level mining are encountered. Longwall is worked in a steeply pitching bed, the coal being sent down a chute to the gangway. The inclination of the bed facilitates ascensional ventilation. A peculiar "gas belt" is also encountered in one mine.*

THE mining town of Carbonado, owned by the Carbon Hill Coal Co., is situated in Pierce County, Washington, on a branch of the Northern Pacific Ry., and is one of the oldest mining towns in the state. Owing to the immense area of coal available and the progressive methods being adopted by the present management, the town will be on the list of big producers when many other mining camps now operating are forgotten.

Many difficulties are encountered here that are of special interest to the mining student. Fortunately, most of these can be overcome with the aid of capital and engineering skill. The Carbon River cuts diagonally across the coal beds, to a depth of approximately 400 ft. along the line of a large fault separating the southern portion of the formation from the folded part on the north. This exposes numerous beds of high-grade bituminous coal.

The strike of the beds on the south side of the river is fairly uniform and nearly north and south; the dip varying from 10 to 80 deg. Due to the depth of the narrow canyon resulting from the action of the river, the company was confronted with a problem in outside transportation. The main difficulty lay in the scarcity of available room for yards, tracks and plants. Finally, the cleaning plant and coke ovens were built about one mile down the river on the first piece of ground available to which the Northern Pacific R.R. connected by means of a spur track. To reach the cleaning plant, the coal is conveyed from the several mine mouths by small steam locomotives hauling from 60 to 80 tons per trip.

This particular mile of track has cost the company considerable money and worry in building and maintenance, because of the loose character of the hillsides, which necessitated the building and driving of tunnels and the placing of cribbing and sheds, to prevent land slides. In this connection boilers, hoisting engines and tracks have more than once been retrieved from the river bottom. On the other hand, these difficulties are somewhat offset by the amount of available coal to be won by drifting in at water level.

Most of the operations have been confined to water-level mining, although a few slopes have been sunk on the different beds. Some of these have been abandoned. On the southwest side of the river a slope has been sunk nearly 2000 ft. on the Wingate bed. Higher up the river, on the same side, a new slope 8 x 16 ft. in the clear has been sunk 1200 ft. on the No. 10 seam, with the intention of tapping five or more beds by means of rock tunnels. The coal from these seams will be hauled by storage-battery locomotives and delivered to bunkers at the slope on each level. A 750-hp. electric hoist has been installed for hoisting purposes, using two 10-ton skips on a 60-lb. double standard-gage track.

For ventilating purposes, the company is using a Sirocco fan, with 200,000 cu.ft. capacity. Both the hoist and fan are installed in chambers hewn out of the solid rock, in order to effectually protect them from slides.

*Paper read at Puget Sound meeting of the American Institute of Mining Engineers.

All the water will be drained to the main pumping station at the lower level, where two centrifugal pumps and one Aldrich quintuplex pump will discharge it to the surface.

The fundamental principle embraced in this mine is the consolidation of several units by centralizing the operations, thereby eliminating or reducing the overhead expenses of hauling, pumping and ventilation. Another feature used in conjunction with this system is the driving of all gangways in rock (foot-wall), connecting the rock chutes to the coal bed above every 20 or 50 ft., as the conditions may require. Some of the advantages to be derived by driving rock gangways are as follows:

First, a saving of coal is secured as well as an increased output by working several levels simultaneously, if desired. Under the old system gangways, on pitching seams, were invariably driven in the coal, making it impracticable to work the lower levels until the upper ones were worked out. If it became necessary to commence on the lower levels before the upper levels were finished, a barrier pillar had to be left in to protect the upper gangway. As will be evident, this usually ended in the loss of the barrier pillar, and, in many instances, the gangway also, due to robbing too close to this roadway, not forgetting poor Jim, or some other good official, who "got it in the neck" through following instructions for more coal.

The miner is exceptionally rare who can not cite cases of lost coal, due to the difficulty in keeping open the gangways. Neglecting the future is a common error in the history of coal mining. This mistake is often attributed to the shareholders in their undue haste to participate in dividends as soon as they are able to dump into the railway car.

A vast difference exists between mining methods in the West and those followed in other countries. When a mine is opened in Europe the owners endeavor to extract all the mineral possible. In the West the custom is to abandon a mine when a little difficulty is encountered or when the profits run low, and open another one, leaving behind, in many cases, considerably more coal than has been extracted. Our motto is: "A new mine every 20 years; a new boss every two years." Rock gangways will put a check on this waste by providing an outlet which, under proper management, should extract every ounce of coal in the lifts, at the same time allowing the management to work two or more levels simultaneously.

The second advantage is that of ascensional ventilation. Upon the completion of the upper working the lower lift is advanced under other methods up to this abandoned gangway, which is usually caved tight. Then comes an increased cost in addition to inefficient ventilation. The chief feature in the ventilation of inclined beds is to so arrange the air current that the circulation will be ascensional, more especially in seams generating marsh gas. The reason is obvious. Marsh gas (CH_4) being lighter than air has a natural tendency to rise. Ascensional ventilation is impossible with the top gangway caved.

Third, with the upper gangways caved, the mine workers always feel the dread of being entrapped in the event of anything happening in the working gangway.

Fourth, timber distribution is much easier. With

AFTER A LANDSLIDE THAT CARRIED BOILER HOUSE AND BOILERS INTO THE CARBON RIVER

the upper gangway open, the foreman can distribute the timber to the workings below much more cheaply and effectively than by hauling it up the pitch, in the event of the upper gangway being closed.

Fifth, the cost of re-timbering is reduced. The common method is to extract the pillars when the breast, or chutes, have reached the upper gangway. Insufficient coal is often left to protect the working gangway. This results in the timbers being crushed and the commencement of a cost which never ends, until, in disgust, the gangway, together with thousands of tons of good coal, is abandoned. Invariably this performance is repeated at the next level.

With rock gangways, this cost and loss of coal, if not entirely eliminated, is reduced to a minimum. The initial cost of driving the gangways in rock is generally higher than in coal, but this is soon offset by the many advantages just mentioned.

Owing to the many beds in Carbonado the mining methods employed vary in accordance with the character of the bed, the overlying and the underlying strata, and the inclination of the seam. Probably the most interesting system employed is the 4-ft. Miller seam worked longwall, on a pitch of approximately 40 deg. Successful longwall mining requires a roof of a yielding nature that will settle uniformly. If this condition exists in a pitching bed, ideal ventilation and complete extraction of the coal are assured.

As compared with flat longwall, the pitching beds possess the advantages of requiring less retimbering, no old workings to keep open, no brushing of roadways, no cogs or packs to build, and ideal ventilation. The disadvantages are the possibility of congestion, considering that the coal must be delivered down the main chute, and the possibility of neglecting to keep the wall at a sufficient angle to prevent the break from closing the entire face.

In former years the company operating at Carbonado had endeavored, unsuccessfully, to work this mine on the chute and breast-and-pillar system. Because of the soft swelling nature of the roof, it was found impossible to keep the workings open. Finally, it was decided to abandon them. Eventually another attempt was made, this time on the longwall system. Success attended these efforts and proved that coal beds, like human beings, had their peculiarities, which required different methods in handling.

As in the other beds, rock tunnels are driven in the foot wall and are really more essential to the success of this method than in chute and pillar workings. The gangway is kept in advance of the wall and connected by rock chutes, every 25 ft., to the counter above. The intervening strata being strong sandrock 12 to 15 ft. thick proves effective in protecting the gangway. Immediately above the counter gangway angle chutes are driven into the open wall above. This lift is usually 500 ft. in length with the line of wall face making an angle of approximately 45 deg. across the pitch. This gives a working face of approximately 700 ft. and an output of between 400 and 500 tons.

The face is worked in steps, of 6 ft. each, and generally spaced 25 to 30 ft. apart. In addition to each miner being protected from the falling coal in the skip or step above, the angle of the face prevents the break from closing the wall during the caving process. Owing to the exceptionally soft nature of the roof, sets are placed every 4 to 5 ft. apart, with three to four laggings covering the set. Each miner puts up on the average two sets per shift.

THREE VIEWS SHOWING THE ROUGH NATURE OF THE COUNTRY

Every week end the main sheet-iron chute is advanced close to the face, and the timber in the waste knocked or shot out, causing the roof to cave. At each skip two iron sheets are laid to conduct the miner's coal to the main chute.

Timber distribution is extremely simple with this class of work, the timber being brought down every night and placed close to each miner's skip. In the event of a shut-down, as the result of a strike or other cause, it is necessary to place cogs at the corner of each skip, also at the bottom of the wall close to the angle chute; the next step is to remove the sheet iron and cave the roof in the waste close up to the cogs. The wall then will remain open with little attention.

One other bed is perhaps worthy of mention. This

is the Wingate seam, which has been the subject of much discussion among mining men. This measure averages approximately 5 ft. 6 in. in thickness on a pitch, varying on the lower levels from 10 to 35 deg., and is worked on the breast-and-pillar system. The first three levels have been partly worked out and the present operations are on the fourth and fifth levels. On account of the slight grade, water is used to wash the coal down the sheet-iron chutes to the gangway.

Since this coal is of a friable nature, with a tendency to create considerable dust of a dangerous character, the water system serves two purposes—that of keeping down the dust and at the same time causing a great saving in tracks and ropes which otherwise would have to be employed to convey the coal from the working face to the gangway. From a dam in the upper levels water is conveyed by a 6-in. pipe to the working gangway. Connections are made here and the water conducted by 1½-in. pipes up to the face of each breast or pillar, where a tap is placed and a piece of hose is attached, enabling the miner to turn the stream of water in all directions. Water sprays are also placed at each crosscut nearest to the face on the intake side, facing the air current to effectually saturate the dust-laden atmosphere, thereby reducing the danger of a dust explosion to the minimum.

In the past this mine experienced considerable trouble with what the miners call "bumps," killing a few men and injuring many others. In addition to the injuries to the men, the mine in and around the vicinity of the bumps, sometimes for a considerable distance, was badly wrecked. Without the slightest warning, timber, coal and sheet iron flew in all directions, killing or maiming the miners close by. Cogs placed on opposite sides of 20-ft. breasts were discovered locked together in the center as if there had been a head-on collision; 20-ft. breasts were filled tight with coal from the opposite ribs; pillars were scattered; crosscuts closed—everywhere a mass of wreckage which often defied the fireboss in his efforts to locate himself.

These bumps, while violent, are not so extensive; that is to say, they do not cover such a large area as

A VIEW IN ONE OF THE PITCHING COAL BEDS

FOLDS AND FAULTS IN THE NORTHERN PORTION OF THE PROPERTY

do the bumps in the Crowsnest Pass. The primary causes of these bumps are undoubtedly common to both localities for, if we had no cover, we would have no bumps. The action of the bumps in the two regions, however, are entirely different.

Mining experience has been dearly bought, but, owing to changes in the methods of working at Carbonado, it is gratifying to believe the danger referred to above is eliminated, since there has been no recurrence of these disasters for several months.

Among the other troubles in connection with the working of this mine is the gas belt. Occluded gases, under heavy pressure, have been encountered in the upper levels, necessitating the stopping of the levels when the gas belt is reached. It is claimed by the older workmen that a hard formation of coal on the outside of this gas belt is encountered. Immediately this hard section is pierced the coal changes in character and blowouts of gases occur, filling the gangway for a distance of 2000 to 3000 feet.

When we stop to consider that occluded gases exist under pressure that is proportionate to the weight of the overlying strata, we can easily imagine the dangers attending the operations when approaching such a locality as that described. The removal of the coal leaves this pressure unsupported, allowing the pent-up gases to burst forth in large volume. These occluded gases, chiefly marsh gas (CH_4), are the result of coal formation and always have a tendency to escape. When, however, the strata adjacent to the coal bed are impervious to these gases we have a gaseous seam.

Approaching this gas belt, the first indication of close proximity is noticeable in the coal. Shiny streaks, with a black-lead luster, two to three inches wide appear in the bed, next the hard coal, sometimes several feet in thickness, is encountered; after penetrating this for a few feet, distant rumblings are heard, accompanied by the splitting and cracking of the coal, due, undoubtedly, to the pressure behind. To the experienced miner this is an indication of danger ahead. Shortly afterward the noise becomes more pronounced, having a decided pounding effect, similar to the report of quick-firing guns. Immediately behind this hard barrier soft coal of an oily nature, having an odor somewhat similar to kerosene and which may be easily ignited by applying a lighted match, is encountered.

Up to date the company has not devised any practicable means of overcoming this difficulty. In other words, a few schemes, such as boring, etc., have been tried, without success. Neither has it been possible to accurately estimate the extent of this gas belt.

Nothing unusual or difficult has been found in the other mines, all of which, with the exception of the Douty seams, will be embraced in the consolidation scheme. It may also be of interest to mention the other progressive schemes outlined by this company.

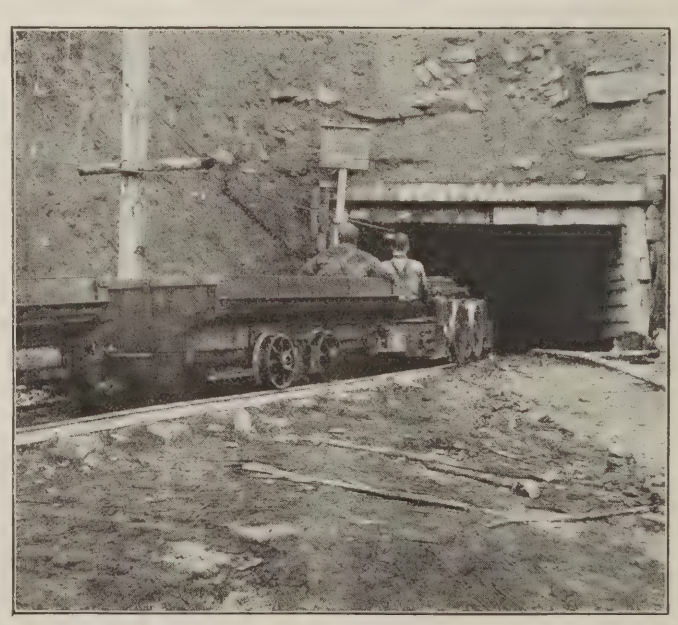
Among the many other drawbacks encountered in coal-mining operations, the company realizes fully the importance of the labor problem. Due, possibly, to new industries springing up and other causes, the company has experienced difficulty in securing sufficient trained men to keep up the necessary work. It has waked up to the fact that in order to encourage settlers it is necessary to pay more attention to their home comforts. With this end in view, it is demolishing the old shacks, replacing them by modern plastered houses, with electric lights, hot and cold water, baths and toilets, fences, cement sidewalks, etc. In addition to this, it has erected the largest and most up-to-date wash-house in the state, built of hollow tile brick. Included in this building are the foreman's wash-house, rescue and first-aid rooms, with separate reading rooms for both miners and officials. The surroundings will be laid out in lawns and ornamental shrubs.

These, among many other improvements proposed, will eventually repay the company by encouraging a good class of married people to make this place their home. In this connection, mention should also be made of the broadminded plan to build a block of officials' homes, knowing from experience that "all is lost," as it were, without good officials. This, to my mind, is one of the most practical moves yet made. It is hard to realize anything more embarrassing and humiliating than for a foreman to find himself housed in a shack next door to, we will say, an ignorant foreigner of anarchistic or I. W. W. persuasion. Those who have been in official positions in and around mining camps, especially those who have children, will readily perceive the soundness of the company's efforts in the endeavor to encourage a good class of officials.

In conclusion, credit should also be given to the state inspectors and others for their endeavors to educate the coal-mining officials by compelling them to pass examinations. This will undoubtedly bring its reward by planting seeds which will eventually germinate into a more ambitious and intelligent class of mine officials.

THERE IS MORE to the transportation problem than moving freight from its origin to its destination with dispatch. The shipper and the receiver both play important parts. When coal operators are shipping trainloads of coal to the seaboard with no ships in sight to receive them, when manufacturers are receiving coal which they cannot store, when jobbers and speculators use cars for warehouses, they are contributing to the confusion and helping to increase the car shortage. One of the remedies for the coal shortage is well known to all those connected with the coal industry. That is, coal must be stored in the summer in excess of requirement for excess consumption in winter. This coal must be stored at the point of consumption.

Power of Coals and Gas



BY W. D. OWENS
West Pittston, Penn.

Good bituminous coal produces about 14,450 B.t.u. on combustion, while one pound of this same coal will generate 12¼ cu.ft. of combustible gas, weighing 0.045 lb. per cubic foot. One thousand cubic feet of this gas, weighing 45 lb., will develop about 1,000,000 B.t.u. of heat, but 45 lb. of coal in combustion with oxygen will only produce 14,450 x 45 = 650,250 B.t.u. Bearing this fact in mind, it would seem more economical to relieve all bituminous coal of its volatile gases and use the product for combustion. The saving from this method would seem to amount to about 54 per cent. over the best results obtained from the present practice.

The Government testing plant at St. Louis has opened the eyes of the scientific world to the merits of consuming gas instead of coal to develop power. One of the tests showed that it required 5.27 lb. of Illinois (Springfield) coal to develop one horsepower-hour, while only 1.79 lb. of the same coal converted into gas produced a horsepower-hour. Of an Indiana coal it required 4.53 lb. to produce one horsepower-hour by the steaming method, but 1.61 lb. of the same coal converted into gas developed the same power.

This discovery led to the testing of the power of lignite, which is the poorest quality of the various grades of coal. It was found that it required 10 lb. of lignite by the steaming method to produce one horsepower-hour, while but 2.82 lb. of this coal was necessary to develop one horsepower-hour by converting the same into gas. This shows a better result from lignite by 100% than is obtainable from either Illinois or Indiana coal through the steaming method.

The Geological Survey states that we have about 480 square miles underlaid with anthracite coal in Pennsylvania. This, to be sure, is a great bed of fuel, but when compared with the square miles of lignite now known to exist in the United States (omitting all bituminous coal) it is but a trifle. The same authority states that there are 246,000 square miles of these low-grade coals.

TRIP OF EMPTIES RETURNING TO MINE OF BLUE DIAMOND COAL CO., KENTUCKY

Methods of Operation

By J. F. K. BROWN
Montreal, Canada

SYNOPSIS — *The chief factor influencing the methods to be adopted in working any particular coal field or bed are the thickness of the coal, the roof conditions, prevailing custom, restrictions, embodied in the lease or deed, and the kind and quality of the labor available. Concerning some of these little can be definitely learned until a certain amount of extraction has been made.*

THE question of the proper method of mine operation is one which always gives rise to much argument and discussion. The reason of this is mainly narrow experience, failure to state all details and conditions, and generally a fatuous conservatism. The worst practical effect of such divergence of opinion is often witnessed in the development of coal fields which have not been long enough known to create or evolve methods peculiarly their own and most suitable to their particular conditions. In such cases it is often possible to find mining methods brought from one experience, one field, sometimes one mine, applied to conditions to which more mature judgment would ascribe another remedy. The policy pursued appears to be: As it was in the older country and the older district, so it must be in the new.

On the other hand, the propagation of definite and well established systems when accompanied with deliberate judgment has much to recommend it. In many cases this may save much costly experiment under unknown conditions. The North of England mining districts are probably the best examples of world-wide perpetuation of special systems, and their men the most migratory of miners. Thus it happens that in various fields scattered over the coal-producing continents the methods and even the local mining terms of the Lancashire and Yorkshire miners are in use today.

From the point of view of the investigator of a new coal area, the factors that point to and influence the method of mining which may be adopted are mainly: (a) Thickness of coal; (b) condition of the roof; (c) custom; (d) special reasons connected with the leasehold; (e) labor.

About the only point upon which there is something approaching unanimity in regard to methods of operation is that thick coals should not be mined on any other system than some method of pillar-and-chamber extraction. Thin coals, on the other hand, may be worked by either the longwall, pillar-and-chamber and entry systems.

Sound engineering backs the argument in favor of the one way of mining thick coals, since the roof of a thick coal would be liable to cause trouble so great that it could not be controlled, if left completely without support as in longwall, or if the supports are not large and properly proportioned to the thickness of the bed. The longwall method does not provide these conditions, and in the thick coals insufficient material is made in the course of mining with which any attempt could be made to pack the waste spaces left behind after the coal has been removed.

With the advent of cutting machinery and loading and conveying devices, all of which tend to increase the daily output, the limit of height beyond which longwall is not feasible, as opposed to pillar systems, has increased. Machine methods have increased the rapidity of face advance to such an extent that fresh roof is exposed practically every night. This eliminates the most frequent cause of coal-mining troubles—namely, deterioration or weathering of the roof stone in position, whereby it fails to carry the weight and do the work it did when first exposed.

As a general rule, however, when a coal bed is 4 ft. and over in thickness preference should be given in the first instance to pillar systems, provided, as already stated, no other conditions predominatingly influence the situation.

With coals below this height—and there are now few coal fields that are not already facing this problem—there is the choice of extraction methods already outlined. It is in discussing how coals of approximately this height and lower should be recovered that the greatest diversity of opinion develops. It is fortunate, however, that few if any specific considerations of the thickness of the coal with the exception of extremely thick beds really exercise a determining influence on methods of operation.

Conditions of the Roof

The importance of the roof conditions should be readily appreciated. It is important in preliminary investigation to know as much as it is possible to know about the roof in addition to the more usual and more readily acquired data on the thickness of the bed or its analysis. In many coal-mine examinations these facts are noted largely as matters of habit, there being always a tendency to pay small attention to them since the coal is after all the reason for the work being done and the object of the inquiry. But it is vitally important to remember that the best coal in any field may be worthless as a commercial proposition if it has to be worked under a bad roof.

Unfortunately it is not easy to collect data about the roof from preliminary examinations. Gathering information about the coal is a much simpler matter. Neither the roof stone nor the coal may outcrop anywhere on the ground, and furthermore an outcrop of roof rock is not always a reliable indication of what the material will be like underground, where it lies in its natural state and has not been subjected to weathering. In some cases outcrop exposure may cause improvement, in others deterioration. Boreholes do not answer the question satisfactorily, the size of the core brought up being far too small for any judgment to be formed concerning the probable action of the roof under any method of mining afterward adopted. Again, too, it is not just the rock immediately above the coal that

can rightly be termed the roof—it is the relationship between the immediately overlying rock and the succeeding strata for an indefinite distance upward that is the real factor in answering the problem of roof behavior.

The most satisfactory method of ascertaining with some measure of accuracy just what a roof may do under future working conditions is to make an actual trial extraction. Whether special or ordinary methods are followed in taking out this trial tonnage is largely immaterial because the trial period cannot commonly be extended over a long enough time to develop into a system. The mining of the small tonnage is usually enough to provide a good idea of what may be expected in the near future. Failing this, judgment is best based on the results of the boring—that is, the drill records which show the approximate thickness and relative position of the various strata over the coal. This knowledge, augmented by experience gained in the same or other fields, will lead to a fairly accurate summing up of the underground conditions as they may be expected to exist when operation has been proceeded with for a considerable distance from the outcrop and after weight begins to tell.

Cost of operation is the limiting factor anywhere, and is the only standard of measurement by which the roof conditions can be properly estimated and adjudged. It is a difficult task, however, and one not always possible, to clearly define the relative influence on costs of which each part of the mine operations is the cause. Thus it is possible to say that the cost of timbering amounts to so much per ton, but it is not so simple to say that this roof cost so much per ton.

Three Classes of Roof

For purposes of rough comparison roofs may be considered as of three classes—good, bad and medium. Bad roofs are such that no method of mining can be operated under them. Grading into the medium and finally into the good groups the advantages that one system of coal mining possesses over another become more understandable and appreciated. Thus it becomes reasonable to assume that the worse the roof the more coal will it be necessary to leave behind for support and the more surely must the operating concern make up its mind to loose in the end.

As better roof conditions are approached such large supports are no longer required, and it is easier to adopt systems that do not call for such a heavy sacrifice of valuable fuel. Finally a stage is reached in which it is possible to extract the coal in one operation and where the problem becomes one of finding proper artificial support.

Modifying these conditions are a number of minor factors, many of which are bound up with and belong to the geological periods when the coal was laid down. Of these stratification and cleavage of the roof are most important. Cleavage of any rock member of any system is developed in three directions, two vertical at right angles and the third horizontal and at right angles to the other two. This does not always apply with extreme accuracy in each case. There may be certain divisions which lie to or away from the vertical plane, but it is near enough to be taken as a general rule. Since the method of deposition and the after pressure and heat cannot always have been the same and equal in each disturbance of strata, it follows that cleavage has become more developed in one direction than in another.

Generally with sedimentary stratification the horizontal parting exhibits the greatest cleavage. This is most pronounced in rocks of fine grained texture such as some classes of shales. The two vertical partings do not so readily show cleavage and in many cases these are not apparent until after operation commences. The important consideration is that there may be between these vertical lines sufficient, if invisible difference, so that the seam is finally found to be capable of being developed and worked in one direction only. This is a feature of underground operation that can only be discovered through experience and experiment.

Complicating this, especially in regard to the horizontal cleavage, is the phenomenon of false bedding, whereby the lines of possible fracture are not parallel to the plane of the coal, but taper down to or up from the run of the coal. This creates lips, steps or edges in the roof, which naturally thicken in one direction. Here again the question of which way operation should proceed may have an important bearing on the method to be adopted, since workings passing parallel to the line of these cracks may experience frequent roof trouble while those operating at right angles thereto may be quite free from such drawbacks.

Passage of Water Along Roof

Equally important, although not so well observed or understood, is the passage of water through or along the roof. The information provided by or deduced from borehole records may not indicate these conditions in the least, because in the core the rock is brought up unweathered and from positions where naturally it has been out of contact with the air. The dangerous feature is the double effect of water and the atmosphere, and that condition only comes about when the extraction of the coal has proceeded for some time.

The double effect of water and air may go so far as to be the cause of virtually a creep in the roof although the phenomenon has not been described as such. This softness of the roof induced by such a combination often proceeds at a more rapid rate than the extraction of the coal, and thus will follow up and render unworkable a section hitherto considered quite minable. Only close study and attention to every detail will be of aid in obtaining knowledge that may be of service before mining commences.

It is of course an admitted mistake to order equipment before mining conditions have become known. Nevertheless this is often done, and underground plant is even more frequently than any other variety purchased before all the simple and primary facts about the the underground conditions of the seam have been ascertained. A considerable capital outlay is involved in underground equipment and its accessories, and to buy these before the information upon which performance can be estimated shows bad judgment.

This fault is not always that of the engineer—much more frequently it is that of a board of directors or a president whose knowledge of coal-mining conditions is of the slightest and who is so anxious to post good reports to the shareholders that he urges the imme-

diate and speedy purchase of equipment before the engineer, if there be any under such circumstances, reports upon what is really required.

Underground atmospheric conditions and the presence of gas have no great effect on the method of operation. In modern practice it is quite possible to properly ventilate almost any system of mining. However, in development these conditions have to be taken into consideration since obviously it is necessary if gas is encountered to have the ventilation designed on a more lavish scale than would be required if gas had not been present.

Custom is possibly the strongest factor in causing the selection of one system of mining over another, and quite often without any consideration of suitability. This is perhaps natural and is a trait that has to be guarded against. An engineer will almost certainly gravitate toward the system to which he has been accustomed. There is, of course, an advantage in this since men accustomed to one system of mining are better able to handle its development quickly and speedily, and undertake its more economical operation later on than those whose experience has been limited to other methods. The disadvantage is that this leaning in one direction may cause the investigator of an unknown coal bed in an undeveloped region to place entire reliance upon what he has seen in the past. He may thereby wrongly prejudice conditions. In an area which is surrounded by operating mines and which has been in operation itself for many years this danger disappears. It is economy to follow custom in this case.

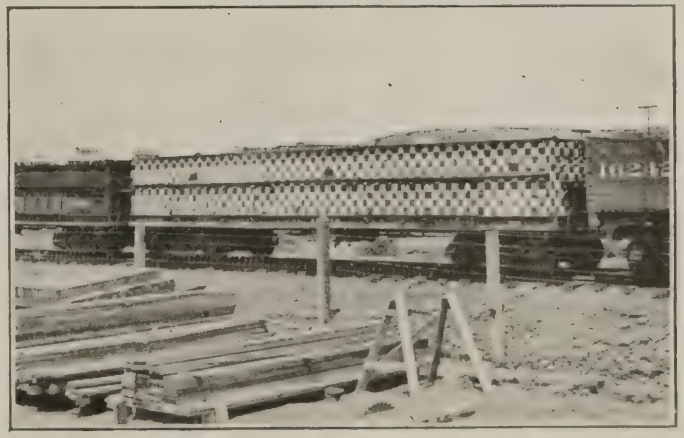
Leasehold Affects Method of Operation

There are a number of conditions connected with the leasehold which may have some effect on methods of operation. For reasons given in the lease or deed of sale a certain method of operation may be prescribed either over the whole or part of the area. In some cases this is not an unreasonable stipulation, as where there are certain important bridges or buildings to be protected; but in other cases such stipulations merely hamper proper development of the field. The shape of the leasehold may also have an effect on mining methods, as may also the grade or pitch of the bed. If the pitch be heavy special methods will require to be introduced. The class of coal may likewise assert some influence and floor conditions may have to be taken into account.

Labor, strange to say, frequently exerts a potent influence on methods of mining because of the effect of custom. In general labor is highly conservative and it is always easier to obtain labor for that class of mining to which it has been long accustomed than for new methods. Thus in longwall districts labor prefers longwall mining, while in pillar districts it approves of that method and would practically refuse to man a longwall mine. Where untrained labor is available this question is not so acute. But the same trouble again arises with ignorant labor, as for example some of the black races, who balk at working under certain conditions because of some unimportant detail. Thus the noise from the working of a longwall roof was enough to ban that system in some coal-mining fields where black labor had to be used.

In general there are but few principles to be outlined as being deciding factors in the question of what method of mining should be adopted. Each case must almost certainly be judged and based on conditions that are present in each field and area and in the surrounding related conditions in the district in general. There is fortunately a vast and excellent collection of description available of methods of mining operated under an almost infinite variety of conditions and those who are in doubt upon this subject cannot do better than search the existing mining literature for details of any system which has been brought into use as a result of underground features which appear to be comparable to those under which mining is contemplated.

Some Advantages of Heat Treatment



By E. A. Pearson
Kingston, Penn.

One consideration regarding equipment that is not given much thought by the average mine official is the kind of axle steel best fitted for mine-car running gears. As a general rule, this kind of material is bought from a price standpoint. No thought is given to the analysis, tensile strength or hardness of the steel. Also, few seem to realize the great advantage of using a heat-treated axle. This latter may cost a few cents a pound more than the ordinary soft steel, but it will pay for itself many times over in a short time.

By heat-treating an axle of say 0.40 to 0.50 per cent. carbon content, a tensile strength of about 125,000 lb. per square inch is secured with a hardness of about 40 on the scleroscope scale. The same analysis steel, cold rolled, gives a tensile strength of about 80,000 lb. per square inch. The advantage in using as hard a steel as possible is self-evident when the extremely hard usage of mine-car service is considered.

By using heat-treated axles, bent and broken axles may be eliminated. This item itself saves considerable blacksmith and car-labor expense. Then, again, where a heat-treated steel is used it is found that wheel hubs are not enlarged to such an extent as when a soft axle is employed. Also, the axles themselves do not wear down as much as is usually the case.

I know of one large anthracite mining operation that has been using heat-treated steel for axles for the last seven or eight years. When this company was using ordinary soft steel it sold from one to two carloads of scrap axles every year, but since using heat-treated axles it has not scrapped one car load. These axles have also shown a decided saving in shop labor.

STEEL GONDOLAS USED AS ARMORED CARS IN MEXICO
THE CHECKERBOARD EFFECT HIDES THE PORTHOLES

Scraper Mining of Thin Bed Anthracite

By E. P. HUMPHREY
Upper Lehigh, Penn.

SYNOPSIS—*Beds of anthracite less than 3 ft. in thickness and pitching less than 20 deg. are difficult to mine. The method here described—namely, loading the coal by means of a V-shaped scraper driven by power—has met with reasonable success during the past two years.*

THE mining of the small beds of anthracite has given rise to many interesting articles and discussions in *Coal Age*. It was therefore deemed worth while to tell how the Upper Lehigh Coal Co. is mining its flat small seams.

The beds being worked with scrapers vary from 16 to 48 in. in thickness and pitch from flat to about 20 deg. When pitching above 20 deg. the problem is a simple one and no scrapers are used; but when 20 deg. or less, difficulty is experienced at once in getting men to work these places, for they do not want to shovel coal several times, use a buggy, or push the coal down a chute—all of which becomes more difficult as the thickness decreases. In fact, in a 36-in. bed any of these methods become quite laborious.

The coal, excepting at the crop, is quite hard and tough. Various conditions of top and bottom have to be overcome. The top may be conglomerate, a soft slate, a soapstone or a "bony" clod. This is sometimes 16 in. thick and either comes down with the coal, forming half-and-half pieces with it, or stays up and must be taken down for safety. It can not be propped as the timbers in many cases would be in the path of the scraper. In places the coal may also be "burned" to the bottom, or a soft bottom that sometimes comes up with the coal makes it hard going for the scraper.

Everything is done to increase the production of each engine. Jackhamers, with cruciform bits, drilling about 2¼-in. holes 6 ft. deep, are used with a mounting consisting of a light metal runway with four adjustable legs. On this mounting the Jackhamer is supported. This makes the work much easier for the driller and overcomes entirely the breaking of drills due to either dropping the machine or not advancing it in a straight line on account of the operator slipping. When one considers that the driller must sometimes lie on his stomach on a pitching floor with no foothold while doing his work, it is no wonder that the pulsations of the machine push him away from the face. Besides overcoming this difficulty and making the drilling less laborious, the support practically replaces one man. By the old method the driller had to have a helper to hold the drill while starting a hole.

As a general rule the air drills are used where the coal is hard and the bed thin, say from 16 to 36 in. Sixteen inches is the lowest that this producer has mined up to this time, and as the scraper is 14 in. high it did not have enough clearance in such places to make allowances for the unevenness of the top and bottom, thus giving trouble by catching. Where the coal is 36 in. or more thick, and softer, especially near the crop, good results have been secured with the hand auger. From data kept for a comparison on this work the consumption of powder was less while the output was the same, for no other reason than that possibly with the auger there was not so much hole to fill with powder. Besides, the auger's record was helped by the softness and greater thickness of the coal. In less than 36 in. of coal the auger is out of the question.

While experimenting to find the best equipment to use for drilling this low coal a twist drill similar to a 1½-in. auger was rigged up, using an old air-driven wood-drilling machine. This worked better than expected. There

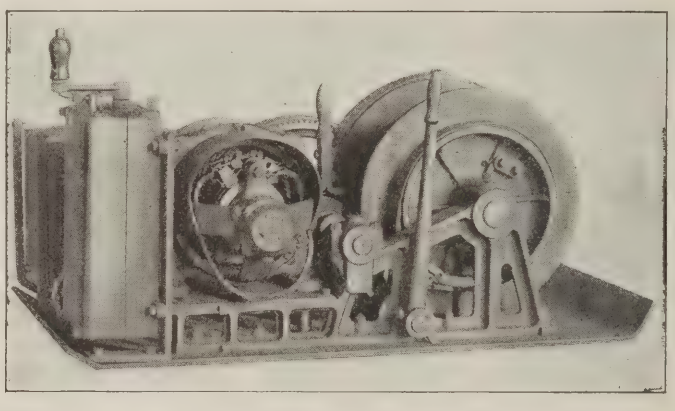


FIG. 1. SMALL HOIST USED TO DRAG THE SCRAPER

was no dust, no pulsation, practically the same weight as the Jackhamer, with no loss in the drilling speed.

An objection to an air machine is the necessity in a long breast of running up the air pipe. An electric motor-driven drill, similar in power to the one used in the experiment and built to do this work, was sought, but no manufacturers with whom correspondence was had carried anything they would care to recommend for the current available—namely, 440 volts, three-phase, 60 cycle—and for the service required. With an electric drilling machine it would be an easy matter to run a flexible armored cable up the rib of the breast.

In the beginning it was the practice to run the power lines along the gangways under an inverted wooden trough nailed to plugs driven in holes in the top rock. Three separate No. 6 weatherproof covered wires were supported by porcelain cleats. This troughing was expensive to place and maintain, was not foolproof in wet places, and the trough could not conveniently be used again. A three-wire lead-covered heavily galvanized armored cable is now used, and this gives perfect satisfaction. Of course, this cable is more expensive initially than the three separate conductors, but the cost shows that after it is used twice the expense is even. This is due to the ease with which it may be strung. Holes can be bored into the coal on the high side of the gangway, plugs driven in, and the cable hung up on hooks. It is absolutely foolproof, and when painted with a heavy oil is practically indestructible. At various convenient places junction boxes are established with switches and fuses.

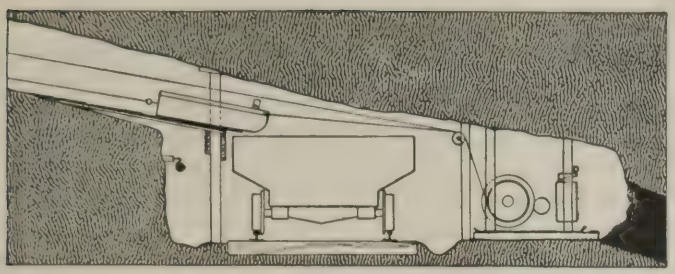

FIG. 2. ARRANGEMENT OF HOIST, CAR AND SCRAPER

The type of scraper engine used, of which eight are employed, is a double-drum machine equipped with a 5-hp. motor. These machines are made by the Pneumelectric Machine Co. and some of them have been in daily operation for nearly two years without a repair. The drums have a capacity of 900 ft. of $\frac{3}{8}$-in. or 500 ft. of $\frac{1}{2}$-in. wire rope. The lighter rope is the one normally used for both pulling and tail ropes. Experiments were made with a $\frac{1}{4}$-in. rope for the latter purpose. Overall dimensions of the engine are 44 in. wide, 38 in. long and 26 in. high. The machine weighs 1650 lb. It has been found that the power consumption averages about 100 kw.-hr. per month per engine.

The scraper is made of No. 10 sheet steel, as shown in the illustration. It is open on top about 48 in. wide in the front, and when filled holds about 8 cu.ft. of coal. In some places, where the bottom is regular, the back and side plates are riveted together, making a solid construction with a minimum leakage. Where the bottom is irregular it was found that a hinged connection between the back and the side plates gave greater freedom and allowed the scraper thus constructed to follow the bottom and not lose as much coal as a rigid one would. A chain bridle is used in the front for attaching to the pulling rope, and a ring is bolted to the back plate for the tail rope.

The scraper has no bottom, so the operation of pulling it over the top of the car empties it. An important feature for its successful operation is to have the bottom edges of the back and side plates bent inward. This keeps the scraper under the edges of the coal and stops the tendency of the device to ride over the top of the pile. The front crossbar, which keeps the scraper open, is arched or elevated to allow the lumps to enter without raising it, also to prevent pulling the big lumps back up the breast.

FIG. 3. THE SCRAPER IN A ROOM

Another detail which in itself is a simple one, yet of great convenience, is the use of a low lift shovel, one in which the end of the handle is about 10 in. from the bottom rock when the back of the shovel is flat on the floor. This keeps the men's hands from rubbing on the roof when shoveling.

The manipulation of this scraper is as follows: The place to be mined is first opened up about 20 to 30 ft. from the gangway and 15 to 18 ft. wide, with a place on the other side of the gangway on the center line of the breast for the engine. This is an opening generally about 5 ft. deep, 4 ft. high and 6 ft. long. The hole is made chiefly in the coal, with a little of the top shot down for headroom. The opening work in the breast is done before the preceding place is finished, so that the output is not decreased. This also removes the blasting sufficiently far from the engine, when it is in place, so that a few planks will protect it.

FIG. 4. METHOD OF DRILLING EMPLOYED

To move the engine a truck is placed in front of it, and, with a few skids and pipe rollers, the machine can pull itself up onto the truck. This is done by hooking one of the ropes on the old platform across the gangway. The base of the engine is made of one piece of plate with the front and rear ends turned up, and it is especially adapted for sliding around, so that if the distance is short it can be pulled along the gangway on its own base, the power being supplied to the motor by the flexible cable.

Referring to the drawing (Fig. 2), the general layout is shown. The gangways are driven 9 ft. wide and 4 ft. high on the low side. A low-type car, 41 in. in overall height with 92 cu.ft. capacity, equipped with Hyatt roller bearings, is used for the low bed. The pulleys on the crossbar in front and above the engine keep the ropes from rubbing on the cars. At the face of the breast an adjustable prop similar to a screw jack, with pointed ends upon which the top snatch block is fastened, is placed. This adjustable feature is a good thing. It allows the prop to be moved across the face, which is necessary for thorough cleaning, with the least expenditure of time and effort.

The method of mining has varied widely. If the top will permit, the breasts, when 30 ft. above the gangway, are driven 50 ft. wide. In other instances they are as narrow as 24 ft. They vary in length from 100 to 360 ft. It has been found that 200 ft.

is the limit for efficient operation on account of the time required for the scraper in moving up and down the breast. The scraper travels about 145 ft. per minute, which is the maximum speed that can be used and still maintain a nearly full load on account of the irregularities in the bottom.

Some of the places are worked with only a day crew of four men—a miner and a laborer in the breast, the engineer and one laborer on the car leveling and picking out refuse. In some cases there is no man on the car, the engineer doing the changing and leveling of the cars. The usual practice for this crew of four is to load out the coal in the morning from the previous afternoon's firing and blast their next day's coal just before leaving in the afternoon. Sometimes they fire in the morning if the coal is all loaded.

Other places use successfully, in addition to the day shift, a night shift of two men—a miner and a laborer—whose duty it is to fill the breast with coal and shovel it away from the face so that the next morning the miner can drill and the laborer load out the coal. The man on the car can often be done away with and used as a scraperman in the breast, while the miner and laborer are drilling. This is done in the places where small or 45-cu.ft. cars are used, the engineman doing the placing. Usually a trip of from four to six cars is brought in and run down one at a time to the platform and loaded.

Four Cars Per Hour Have Been Loaded

The best loading record at this time is 32 small cars per shift of eight hours. The crew consisted of the night shift of two men bringing down the coal and the day shift of four men who loaded it and fired a few shots to make more coal. The coal averaged 36 in. high and the length of the haul for the scraper was 175 ft. About 50 minutes were taken from the possible loading period for the changing of the trips. The crews are all made up of "company men" on account of difficulty in getting the places worked on a contract basis.

In performing the first mining it pays to leave large pillars at least 25 ft. thick for the robbing, unless it is possible to take this all out the first time. When robbing, the engine has to be placed again, this time in a new position on the center line of the pillar, and the pillar skipped till all the coal is removed. Of course, some of the coal is lost by being shot out too far into the open breast, but this does not amount to much if the clod and other refuse are always gobbed against the outside rib when doing the first mining. This gob not only keeps the coal from scattering into the dangerous inside section, but aids in breaking off the cave when the pillar is removed. When robbing it is well to place a few light props to indicate any settling. When pillars are big enough they may successfully be robbed by driving a hole up through the center and bringing the top back through it.

The proposition of driving more than one place side by side with the one engine and using a system of snatch blocks has not proved to be successful. It means a bigger output per engine and is not impractical, so that attempts are still being made toward that end.

The section of the gangway shows the relative positions of the loading platform, the car and the engine. For the platform two light props are placed about 12 ft. apart, on which are spiked two planks at the proper height for the car. From these about five 2-in. planks about 10 ft. long are run up the breast, upon which iron sheets are placed lapping each other and parallel to the gangway. These are all nailed to the planks except the one nearest the gangway, which is arranged so that it can be pulled out to cover the gap between the car and the platform and prevent spilling. It can also be pushed back when not in use.

To aid the man in leveling the cars a common garden hoe is used, a shovel being of little value on account of the low top. To secure the engine and keep it from pulling out on the gangway four light props are wedged between the top rock and the engine bedplate. The engine is first run in on two ties, to aid in setting it up fairly level so that the motor may get oil properly.

The manner of supporting the power cable is shown, except that between the breasts the plugs are in the coal and not in the rock. The reason for carrying the cable on the high side of the gangway is to keep it from being damaged or shot down when the breasts from the lower level break through. At a platform the cable is passed under it. The lead to the engine is run over the top of the gangway.

For the past two years these methods, with slight modifications, depending upon conditions, have been used in small beds. Before adopting the present electrical equipment an air engine was used. This engine was in every respect similar to the present electric machine, except that it was driven by compressed air. The electric engines, however, proved more efficient and were consequently adopted. For the problem of mining thin beds, pitching within the limits of 0 to 20 deg. and varying in thickness, from 18 in. to 4 ft., this method of loading with a scraper is one solution.

Legal Department

Right to Use Surface—Separation of ownership of underlying coal from ownership of the surface by a grant or reservation of such coal implies grant to the owner thereof of the right to use so much of the surface as may be reasonably necessary in mining and removing the coal. **(Iowa Supreme Court, Hammarstedt vs. Bakeley, 166 Northwestern Reporter, 729.)**

Employer's Responsibility Under Mining Acts—In the case of Whittaker vs. Valley Camp Coal Co., 103 Atlantic Reporter, 594, in which plaintiff sued on account of injuries sustained in a mine by coming in contact with a post standing near a track while performing his duties as brakeman, the Pennsylvania Supreme Court lately quoted the following statements of law bearing upon a mine owner's liability for injury to an employee, according to whether the cause of injury may be attributed to negligence of the owner or of a statutory mine foreman: "Where the act imposes upon the mine owner a specific duty as to the arrangement and management of the mines, the mine owner cannot protect himself from liability by showing that the structure in question was put up by direction of the mine foreman, at least wherever the fact of its existence became known to the owner, but that it would be his duty to remove it; * * * on the other hand, where the act does not call for any particular arrangement or structure, the arrangement or structures ordered by the mine foreman for the purpose of supporting the roof are obligatory and he is therefore not responsible for injuries caused thereby."

Must Find a Market for Screenings

Relief must be granted in the matter of handling screenings in the territory from Indiana westward. This is becoming increasingly evident, according to advices reaching Washington. If serious loss of production is to be prevented, a market must be found for a large tonnage of screenings in the near future. The most practicable way of solving the problem, it is suggested, is to raise some of the so-called conservation orders and allow brick and tile factories, the makers of sanitary ware and such materials to operate at full time provided they will agree to use screenings. It is also suggested that many manufacturers would be glad to store screenings in considerable quantity, which would do much toward ameliorating a situation which is interfering decidedly with the production of lump coal.

President Wilson Issues Proclamation to Coal Mining Industry

Despite the handicaps which the coal-mining industry is laboring against, President Wilson believes that "sufficient coal can be mined in spite of the handicap if every one connected with the industry, from the highest official to the youngest boy, will give his best work each day for the full number of work hours." The President regards the coal situation as sufficiently serious to justify the issuance of a formal proclamation to all those engaged in coal mining. The proclamation in full follows:

The existing scarcity of coal is creating a grave danger—in fact the most serious which confronts us—and calls for prompt and vigorous action on the part of both operators and miners. Without an adequate supply our war program will be retarded; the effectiveness of our fighting forces in France will be lessened; the lives of our soldiers will be unnecessarily endangered and their hardships increased, and there will be much suffering in many homes throughout the country during the coming winter.

I am well aware that your ranks have been seriously depleted by the draft, by voluntary enlistment, and by the demands of other essential industries. This handicap can be overcome, however, and sufficient coal can be mined in spite of it, if every one connected with the industry, from the highest official to the youngest boy, will give his best work each day for the full number of work hours. The operators must be zealous as never before to bring about the highest efficiency of management, to establish the best possible working conditions, and to accord fair treatment to everybody, so that the opportunity to work at his best may be accorded every workman. The miners should report for work every day, unless prevented by unavoidable causes, and should not only stay in the mines the full time, but also see to it that they get more coal than ever before. The other workers in and about the mines should work as regularly and faithfully so that the work of the miner may not be retarded in any way. This will be especially necessary from this time forward, for your numbers may be further lessened by the draft, which will induct into the Army your fair share of those not essential to industry. Those who are drafted but who are essential will be given deferred classification and it is their patriotic duty to accept it. And it is the patriotic duty of their friends and neighbors to hold them in high regard for doing so. The only worker who deserves the condemnation of his community is the one who fails to give his best in this crisis; not the one who accepts deferred classification and works regularly and diligently to increase the coal output. A great task is to be performed. The operators and their staffs alone can not do it, nor can the mine workers alone do it; but both parties, working hand in hand with a grim determination to rid the country of its greatest obstacle to winning the war, can do it. It is with full confidence that I call upon you to assume the burden of producing an ample supply of coal. You will, I am sure, accept this burden and will successfully carry it through and in so doing you will be performing a service just as worthy as service in the trenches, and will win the applause and gratitude of the whole nation.

Railroad Mines Not to Get Preference in Car Supply

Mines owned by railroad companies are to receive no preference in car supply, according to a ruling made by A. H. Smith, regional director for the East, when an actual case came before him for decision.

Mines to Receive Essential Equipment

Through the newly created equipment section of the Fuel Administration, an arrangement has been made with the War Industries Board which is tantamount to a blanket priority order covering essential equipment for coal mines. The automatic priority does not apply to equipment for new construction or expansion. When materials are needed under those circumstances, the regular priority certificates must be used.

Inspection Leads to Large Coal Saving

A saving of coal equivalent to 350,000 tons annually already has been effected by the Fuel Administration in its conservation campaign among the steam power plants, it is stated officially. This saving has been effected through the inspection of 300 plants. It is the intention to inspect each of the 250,000 steam plants of the country. The saving is declared to be the result of applying more efficient firing and operating methods. It has been brought about without curtailment of output.

Statistical Section of Fuel Administration Doing Important Work

What is regarded as one of the most effectively organized divisions of the Fuel Administration is the statistical section. Since an enormous volume of data must be collected and tabulated, this section is conducted as systematically as a large manufacturing enterprise. All of the latest mechanical devices for punching and sorting and otherwise handling cards have been installed. The section is in charge of C. E. Lesher, who is handling this work in conjunction with his regular division of the Geological Survey, which compiles coal statistics.

Demands for Coal Continue to Increase

Demand for coal for essential uses continues to exceed estimates. This is particularly true with regard to coal from the low-volatile fields of Maryland, West Virginia and Pennsylvania and the high-volatile fields of Kentucky, West Virginia and Pennsylvania. At the beginning of the coal year the Navy's requirements were placed at 3,500,000 tons. It now is estimated that the Navy's requirements will be on a basis of 8,000,000 tons before the end of 1919. Last month the Navy's demand had risen to a 6,000,000-ton basis. On Apr. 1 it was considered that 10,000,000 tons was a liberal annual allowance for the Shipping Board. The results which have been secured in the shipbuilding program, nowever, are such that the estimate now is 13,000,000 tons.

One of the more phenomenal increases in the estimates is that for bunker coal. At the beginning of the coal year, 13,500,000 tons was assigned for this purpose, with the thought that it was liberal. The figure has now risen to 21,000,000 tons. The advanced calculation as to fuel which would be needed by new industries went decidedly awry. Adding to this the coal needed by plants that have been enlarged and the additional fuel required to keep a large percentage of industries operating on a 24-hour basis, it can be seen how the actual requirements are far in excess of the forecast.

Because the enormous consumption of the East must be met from such a limited area, the difficulties of the situation are becoming increasingly great. The mines in that limited territory are now more than 14,000,000 tons behind their schedule, due largely to difficulties of transportation.

To Demonstrate Rescue Work at Fairs

That a more general understanding may be had of rescue work at coal mine accidents, the Bureau of Mines will conduct demonstrations this year at a number of state fairs. Demonstrations of rescue work will be made possible in a glass inclosure which will be filled with smoke for that purpose. The inclosure will be elevated so that the demonstration will be visible to a large number of spectators. The fairs at which the demonstration will be given are as follows: Missouri state fair, Sedalia; Illinois Centennial state fair, Springfield; Iowa state fair and exposition, Des Moines; Kansas free fair, Topeka; Wyoming state fair, Douglas; Kansas state fair, Hutchinson; Oklahoma free state fair Muskogee; New York state fair, Syracuse.

Coal Exports During May

Exports of coal during May, 1918, as reported to the Department of Commerce, with the figures for the corresponding month of 1917, as finally revised, are as follows:

Exports	June, 1917 Tons	June, 1918 Tons
Anthracite	604,777	378,753
Bituminous	2,291,613	2,205,711
Exported to:		
Italy	58,516	.....
Canada	1,801,776	1,803,407
Panama	38,348	50,871
Mexico	12,328	13,508
Cuba	115,091	110,959
Other West Indies	33,031	25,944
Argentina	17,054	43,035
Brazil	96,040	93,782
Uruguay	2,151	48,105
Other countries	117,278	16,100
Coke	152,948	141,194

Brief Washington Notes

Using the returns from the first of the lightless nights, the Fuel Administration estimates that more than 1,000,000 tons of coal will be saved yearly. The saving in the Borough of Manhattan alone is figured at 40,000 tons a year.

Communities having conveniently at hand a supply of wood may be cut off from any supply of coal if the state fuel administrator sees fit. The attention of the state administrators has been called to the fact that the order appointing them to office contains their authority for prohibiting the sale, shipment and distribution of coal to domestic consumers.

Clay products, lime, cement and glass industries are to be inspected in the near future and rated as to efficiency in fuel consumption. An opportunity to effect savings will be made before the inspection. The furnace industries have the reputation of being profligate in the use of fuel. It is believed that several million tons can be saved by enforcing conservation.

The Secretary of War has sent the following letter to the Fuel Administrator:

I was greatly impressed when I learned recently about 150 retired miners in Mercer County, Penn., recognizing the nation's urgent need of increased fuel, had volunteered to go back to the mines and serve their country there.

This is the spirit which free and liberal government always engenders and which insures the triumphs of our arms and aims. I should like, through you, to send a personal greeting to these heroes of the pick.

Help Find This Man

Coal Age is in receipt of a request from a soldier at Camp Merritt, N. J., to help locate his father, who was a coal miner in Tennessee and left his family four years ago. His name is James A. Nelson; aged about 40; weight 180 lb.; dark complexion; with blue eyes, smooth face; height 5 ft. 11 in. He left three sons, all of them in the service at present, two being in France and one at Camp Merritt. The mother died last April. If anyone reading this notice knows where this man can be found, see that he communicates with his son, Joseph A. Nelson, of the Headquarters Company, War Risk Insurance Department, Camp Merritt, New Jersey.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The labor situation seems somewhat discouraging, partly because it has fallen into an era of recrimination instead of coöperation. There are charges and countercharges, and the industry no longer says one and the same thing. Some have spoken for temperance so forcibly that others have been prompted to deny that the miners are as a whole drunken, which of course no one has been foolish enough to affirm. Some have pointed to the revelry of those who profane the church festivals by improper observance, and in so doing have aroused the antagonism of those to whom the festivals are occasions of religious—and not riotous—celebration. Others have condemned the irregular work of the mine workers with such persistence that the mine workers have countered, charging inefficiency against the operators.

Now clearly this is no time for scolding or recrimination as against any class as a whole. Every remark should be carefully guarded with the intent to prevent too general a reference. The patriotic, temperate and conscientious men should not be offended by broad generalizations directed against a whole class, part of which, it is true, deserves criticism, but part of which is doing its utmost to serve the nation.

There are causes for the harshest of criticism. Some should be directed against certain operators and some against certain miners. The greater part of the criticism must be against the latter, partly because many are foreign and not therefore ready to support us in the war, but partly also because the needs of the hour have not been made plain to them.

But do what we will, some will be made angry. The more angry some are made the better it will be. Criticism which hits all miners alike, however, only lightens the burden for the worthless part of our personnel, which should be loaded, not with a part, but with the entire onus. Classing mine workers in a common category without any respect of persons results in antagonizing the elements by which alone our battle may best be fought.

It is the mine workers who can decree temperance, who can restrict religious observance to the daylight mass, who can require the 8-hour day, who can put their condemnation on all who go to festivals and horse fairs and on all who take their guns from the wall and hunt groundhogs and rabbits when they should be mining coal. As the mine workers "put over" the Liberty Loan, so they can "put over" the steady working day—the 48-hour week. They can and will if right leaders are chosen. But if we are going to have a quarrel as to the relative patriotism, temperance, patience, endurance and even the piety of the two elements of operation—employers and employed—then we are starting the war a-wrong and need to go unsnarling all the material with which we have to work.

There evidently has been an outpouring of energy and right-minded purpose in the coal industry, for though we have lost men the tonnage is nevertheless higher than ever. Some are keeping up the fight, though there are doubtless far more slackers than there should be. Let us be careful of vexing the patriotic men by firing volleys of abuse at the minority of slackers among them.

The man who has nothing but blame in the armory of his corrective effort is quite liable to find that it will not serve his purpose. Judicious praise in liberal measure should welcome every patriotic effort. For instance, for one man who quits a corporation to secure a refund on his Liberty Loan there are dozens who quietly pay up as the payments become due and some who pay even before they are due. It is just as easy to win out by encouraging these men as by condemning the others, and a little failure in diplomacy may anger the honest men while not rectifying the faults of the delinquents.

> *THE miners should report for work every day unless prevented by unavoidable causes, and should not only stay in the mines the full time, but also see to it that they get more coal than ever before. The other workers in and about the mines should work as regularly and faithfully, so that the work of the miner may not be retarded in any way. This will be especially necessary from this time forward, for your numbers may be further lessened by the draft, which will induct into the army your fair share of those not essential to industry.*
>
> *Those who are drafted but who are essential will be given deferred classification, and it is their patriotic duty to accept it. And it is the patriotic duty of their friends and neighbors to hold them in high regard for doing so.*
>
> *The only worker who deserves the condemnation of his community is the one who fails to give his best in this crisis; not the one who accepts deferred classification and works regularly and diligently to increase the coal output.—President Wilson, Aug.* 11, 1918.

All this is written for the operator and his principal assistants. If by any means this review passes to the mine worker it should assume another tone. The mine worker is letting things drift. It is his duty to back the union in its fight for clean coal and contract keeping. It is the duty of every miner to advocate a new attitude toward the whole question of coal production. In the anthracite region the funeral strikes, the little fusses fostered to break the scale, the meetings to create entirely new wage rates should be insistently suppressed. The duty of the mine worker is not fulfilled if he does his personal duty and yet sympathizes covertly with those who are trying to break scales and create new conditions with the Hun in Germany and the friend of the Hun in America as principal assistants. A positive program of nationalism and production is part of the duty of every mine worker. He should not be content with his own vote in the union, he should convince his coworkers. Anything less is half-hearted patriotism.

The demands of the 52 local unions of the northern district of the anthracite region, which includes Scranton and Wilkes-Barre, unreasonable as they are, are not as much to be condemned as the untruthful aspersions with which they are accompanied. It is unbelievable that any men would be found willing to assert that the "coal operators or their subordinates are restricting the output at nearly all the mines." With wages higher than at any time, with some men laying off four days at a time, how can they say also that conditions are unbearable?

Perhaps they are right when they say that now is the time to make an investigation. Perhaps now better than at any time we can find men who will not be afraid to speak plainly about matters and reveal to the world the spirit of covenant breaking which is becoming too common among the workers in the industry. The few malcontents sway the many. Most of the English-speaking miners are punctilious about their honor and the union leaders intend to keep a promise when they make it; but unfortunately there is a turbulent minority always dissatisfied, always

rebellious, which upsets agreements or tries to upset them as soon as those covenants are committed to writing.

The large shortage in car supply is again upsetting production propaganda. Again we have to say "Mine whenever the chance is given." An "if" and an "and" are again introduced into the plea for steady work and this spoils its whole effectiveness. The miner again becomes a casual hand, with all the faults which are inevitable in a casual worker. Of course this does not affect the anthracite region. There are always enough cars there, but it does spoil much good work in the bituminous regions.

Stocking of coal should start again and last till the railroads are relieved of the transit of grain. The earlier grain is moved the sooner the movement will be over, and when it is over the mine worker will have his chance. In giving out cars the possession of a stock pile should be given consideration. The mines which provide these valuable regulators of business should by all means be rewarded. If all mines stock coal, all will be on the same footing; but what a wonderful resource of coal would be provided. An embargo on other merchandise of only a few days would enable the mines to flood the country with coal, whereas that could not be done if the country were dependent on the efforts of the miners.

The note of the President to the mine workers is reproduced in full in the news section. This is an extremely welcome accession to the long list of those who are aiding in the production campaign.

Wage Competition Replaces Price War

President Frank Farrington of district 12 of the United Mine Workers of America (Illinois) is opposed to the practice of paying premiums to miners because this action stirs the men at other mines to demand more money and because the union, in agreement with the United States Fuel Administration, has bound itself to work at the present scale during the war unless the war lasts beyond Mar. 31, 1920. Farrington has protested against premiums in communications he has made not only to the local unions of his own organization, but also in those addressed to the three operators' associations in the state and in letters written to the United States Fuel Administration. He has also taken the matter up with Governor Lowden and with the state council of defense. He urges all miners to work full time and work hard and make no demand for more wages. He is also prepared to go to the limit to have the federal fuel administration close the mines where operators continue to pay premiums. Whereas Illinois formerly had a price war, the operators, having a fixed price, are now engaging in a wage competition which threatens a reduction of their profits to the vanishing point. Frank Farrington knows that profitless operation is demoralizing to the industry and causes unsafe, unhygienic and unfair mining conditions. For this reason he does not approve such unbridled competition for labor, and he opposes it furthermore because it tends to cause the mine workers to break a scale of wages to which they have set their hand.

Want An Increase of 25 per Cent.

On Aug. 5 the delegates from 52 local unions established in every mining section of the northern anthracite field from Forest City to Shickshinny, drafted resolutions demanding higher wages and a government investigation of the anthracite mines. A committee of 12 was appointed to work on a new scale of wages and other benefits. Demands were drawn up which will be presented to the operators by this committee. It is stipulated in the agreement that whatever increase is granted be dated from Aug. 1.

The miners maintain that they are entitled to an increase in wages and to a betterment of conditions because of the unprecedented rise in the cost of living. They say they are making more sacrifices than ever in order to increase the output of coal. The operators know, they say, that the miners would remain at work under any conditions to avoid a crisis next winter, and for this reason they are taking an unfair advantage of them.

The miners unanimously decided to send copies of the resolutions to the president of the district, to the international president, to the War Board, and to United States Fuel Administrator Garfield. It was also decided by the miners that they demand an answer within a month. It is intimated in the Wyoming Valley that unpleasant measures may be taken by the miners if their demands are ignored. The delegates vented no little of their discontent on their district leaders against whom considerable bitterness was exhibited, the complaint being that they had failed to sanction the meeting.

The resolutions, which were unanimously passed, are as follows:

"Whereas, the Anthracite Coal Operators through their publicity bureau and the press of the country, advertised extensively the existence of a shortage of labor and the necessity for an increase in the production of coal, and stated that, if relief were not forthcoming there would be a coal famine next winter, and

"Whereas, it appears that there has been no one willing or able to take up the mine workers' side of this great question and give it publicity, and

"Whereas, it is intimated in these articles in the press that mine workers would be responsible if a shortage of coal occurred, and

"Whereas, we believe that if a careful investigation were made in the proper manner it could be easily proven that the coal operators or their subordinates were restricting the output at nearly all the mines, and

"Whereas, conditions are imposed upon the miner daily such as reduce his earnings and make it harder for him to make a living for himself and family so that the conditions are becoming almost unbearable, and

"Whereas, the operators, knowing our patriotism and love for the cause of our great country at war and believing that we will remain at work under any conditions to avoid a national coal crisis, are taking unfair advantage of us, and imposing conditions on us, which are as bad as we had prior to 1900,

"Therefore, be it resolved, that we court a government investigation of the anthracite mines and urge that the investigation be made through the mines grievance committee, the members of which are the only persons closely connected with the mines and so equipped to know by experience the true conditions of the men in and around the mines, or else by calling together a convention at which representatives of the men in the anthracite region would be present."

The demands which the men make are as follows:

1. That the present war bonus be doubled for outside and inside day work. 2. That time and half time be paid for all overtime worked, and double time for Sundays and holidays. 3. That contract miners be granted an increase of 25 per cent above the rate of pay provided in the Washington agreement. 4. That a minimum rate of $5.50 per day shall be paid to the contract miner and $4.25 per day to miners' laborers.

Pro-German Agent Is Arrested

With the arrest of Joseph Paesteinsch, at Fleming, Ky., it is claimed that a Hun movement to tamper with the mine labor of eastern Kentucky was unearthed. It is said that this man and his associates as agents of the German Government had been endeavoring to start trouble among the miners in an effort to reduce production. As the schemes were discovered early it is not believed that any further trouble will be experienced.

C. J. Norwood, dean of the University of Kentucky, at Lexington, in discussing this matter said: "Scarcity of labor and not Hun agents will cut coal production in Kentucky this year. A large percentage of the Kentucky miners are native born, with only a sprinkling of Germans, Austrians and Italians. Most of these are naturalized, and apparently loyal. Enemy agents so far are having no effect, and the German propaganda has been wasted. Kentucky is fortunate in having a smaller percentage of foreign-born miners than the other states."

EDITORIALS

Record Would Put Blame Where Due

"CONFESSION of a fault," says the proverb, "is half amends." The record of workingmen's time proposed by the Central Pennsylvania Coal Producers' Association and reproduced as a general article last week, if filled with a due recognition of the redemptory value of a frank confession, will be a most valuable stimulant toward larger production. It shows what delays are due to bad places, lack of railroad cars, floods and fires, lack of purchased power, breakdowns, no rails in place, no timber in place, no mine cars, place not cut, lack of air and presence of water and then gives place to one inexcusable item against the mine worker—intoxication—and adds holidays and sickness, which may or may not be excusable. However, two holidays are conceded—Independence Day and Christmas. There is room for two other items. "Breakdown of street car or railroad service" might fill one of the spaces provided and "returning home early" another.

The operator's difficulties, of course, make it impossible to obtain a 100 per cent. record, such as the mine workers may, at any time, obtain and should obtain, if they are in good health and railroad-car service is satisfactory. The operator has to depend on labor supply, and the shortage of labor is hampering him. That is the sole reason for introducing these forms. In nearly every case, it will also be the reason for the failure of the operator to make a perfect score. Labor may be, and often is, to blame for the failure of the operator and the committee which will keep the record will be tempted, if not justified, in writing down "intoxication" as the cause of delay whenever a man goes home because his place is not cut when the reason it is not cut is that the man appointed to do it was intoxicated and would not cut it. There are many other similar temptations to transfer the burden of failure from the operator to the worker, for many of the delays are due indirectly to labor's failure laying labor idle. Such causes are breakdowns, undelivered timbers, mine cars not placed, air ill-distributed and water not removed.

Moreover the temptation will be increased if the man thus delayed goes home at once and makes an hour or two of excusable delay the reason for a day of inexcusable idleness. As has been said, presence at one's work for eight hours can be supplied at any time when a man is well. The mine worker really should give that attendance though it may try him severely if he finds that those who "fly off the handle" and threaten to go home or who are in the habit of leaving work before the whistle blows are given undue preference. His patriotism will also be severely tried if he discovers that when working to remove the cause of delay—pumping the water or ditching it away—he is not credited with pay for his labor.

But in any event as the record is largely a personal record the mine worker should not be credited with another's fault if he really cannot possibly make a complete record. The operator may have to stand the blame even though it is largely not his, but the fault of some human link in the chain which elects to break incontinently. The record will in any event stimulate the operator to greater efforts and analyze his failures in regularity of operation as the cost sheet has analyzed the economy with which his plant is conducted.

It will not be surprising if the record when honestly filled is a little depressing and annoying to the operator unless the committee decides to fill it out by reporting unfavorably the absences of all men who leave their places while the mine is still working or who fail to report on working days, for the shortage of labor and the lack of material and supplies makes a "bull's eye" record almost a phenomenon. Conscience unfortunately will have much to do with this report and conscience is a variable quantity.

One might have wished that "air and water"—lack of air and presence of water—had not been copulated. Lack of air is much more condemnatory than presence of water and it is well to separate these two causes, for the correction of them is quite different. Intoxication and holidays should not be combined, nor floods with fires.

If Coal Had Been Stored at the Mines

IT IS A PITY that in the early months of the year when cars were scarce more coal was not stored at the mines. Had it been done the mines could have flooded the railroads with coal when cars were plentiful.

In the first weeks of this present year less cars were furnished than last year, and yet even last year's cars in January were less numerous than the year before. Early in February the car supply of 1918 became better than in 1917, but up to the Fourth of July in most places coal could have been stocked with advantage. Unfortunately the railroads had failed so completely to meet the situation that few thought well to make preparation for the time when the railroads would be able to supply more cars than were needed to accommodate the daily output.

Should the military draft and other influences continually lessen the ability of the operators to produce coal, and should the activity of the railroads be unhampered, and both propositions seem conceivable, it is quite likely that there will, at times, be plenty of opportunity to load stocked coal. In fact it should be the customary plan during the war to stock coal whenever the mine would otherwise be idle wherever the topography makes such a practice feasible. The steady production resulting would make the practice profitable. In this way both mines and railroads would work at full blast every day, and the mines would be able to furnish assistance to the farmer even in the early summer when car supply is at its best.

Gave Their "Fourth" to the Red Cross

UNDER this head we present a poster this week commending the patriotic work of the men of the Jewell Ridge Coal Corporation, with offices in Tazewell, Va. The mines are at Jewell, Tazewell County, and the coal mine is in one of the Pocahontas measures, No. 8 to be exact. The high quality and smokeless character of the coals of the Pocahontas series fits them well for bunker purposes, and the men who mine these coals have a right to feel that they are more than usually privileged in their opportunity to back up the sailors on the ocean front.

Only a few of the men are shown in the upper picture, which does not include some of those who posed for the photographer. The group had lined itself up in front of the Y. M. C. A. building. The second illustration shows the small schoolhouse and the children merrily at play. George W. St. Clair, the secretary of the company informs us that "we have been fortunate enough to have college graduates for teachers each year." Doubtless this matter came by design and was not wholly fortuitous. The lowest illustration shows the village of Jewell, situated 500 ft. vertically above the drift mouth.

One may be pardoned for listing the names of those who have given Jewell Ridge a preëminence for civic virtue to which no mere size would entitle it. Thomas M. Righter, of Mt. Carmel, Penn., was president, but he died on July 12. George W. St. Clair has been already named in this notice. J. B. Collins, a trained industrial secretary, manages the Y. M. C. A.; J. J. Delp is superintendent and R. J. Blakenship is mine boss. These men are entitled to full credit for creating a generous and devoted spirit in the personnel of the mines.

It is only fair to add that the miners of Jewell were by no means the first to give a day to the American Red Cross. Whole districts have done this. The exceptional character of their sacrifice was the surrender of the Fourth of July to the need of their country. By celebrating that day as they did they gave twice to the cause. They gave the navy coal it could not otherwise get, and it gave the Red Cross a big boost in the financing of its gigantic program.

The One-Industry Nation

GRADUALLY the entire industry of the country is taking one trend, is being focused upon one point —that of winning the war. Steadily we have seen the steel output turned to national needs, and the products of the factories, the mines, the farms, etc., are inevitably moving in the same direction. The progress that has been made toward this end has been rapid since our entrance into the world conflict—more rapid and complete than has been that of some of our allies who have been in the war since its beginning.

We print on page 303 a résumé in abstract from the *Journal* of the British Board of Trade. This shows among other things that at the time the article was published in the *Journal* only the London district of Britain was "on coal rations." Although the coal industry was under complete governmental control, it had not as yet been found necessary to ration any portion of the country outside of the London area.

In the United States, on the other hand, the entire country is "on allowance," and it is believed that all Britain will soon be rationed also.

In the conduct of the war this country has followed closely the example of England, and will doubtless continue to do so. This country has not even yet thoroughly realized that we are at war. In England that realization is a grim and stern reality.

Britain is today prosecuting but one business—that of war-making. It is stated that all other interests are, if not forgotten, at least side-tracked and neglected. Political issues arise which in normal times would create a furore from one end of the land to the other. Today they are settled after a half-hour's debate in Parliament, and if noted at all by the average Britisher they are considered as being merely interesting side shows to the great tragedy being enacted across the channel. The one and only business that occupies the attention of the British is the conduct of the war.

The citizen of Great Britain today has less personal liberty than was enjoyed in the early days of King John before the populace of the realm demanded and received the Magna Charta—yet nobody cares, no one complains. Lloyd George exercises greater power than any monarch who ever sat upon the throne of all Britain, yet no one raises a voice of protest. As one man the English people are working with unshakable determination, full speed, full steam ahead to defeat the Hun.

And as the blue stars upon the service flags displayed from the windows of millions of American homes begin, slowly at first and then more and more rapidly, to one by one change their color to that of gold, America will gain the spirit that now pervades England and France. The time is not far off when we also as well as our allies will have but one business, but one aim, but one purpose. The sooner that time arrives the sooner will that purpose be fulfilled.

The Hand of All for the Help of All

THE war is teaching us that our ideas, our plans and our ambitions must be at least nation-wide, if not wider. The methods and mechanisms we devise are not ours, but our country's. To hold them for ourselves alone is not modesty, but meanness. The things our brain has conjured up to produce more efficiency and greater safety, good will in the industry and health for the worker, should be communicated to others for their imitation. We who want to read and absorb such ideas should be as ready to distribute what we have as we are to accept those which others have conceived.

Thus we all owe a duty not only to the industry but through the industry to the nation. On Sept. 12 *Coal Age* will have a Safety, Welfare and Convention Number in honor of the National Safety Council, which has done so much to save lives by arranging for a free exchange of ideas on safety and by stimulating safety practices in all forms of industry by cartoons and posters.

Coal Age invites its readers to send articles on safety and welfare for that issue. Its many readers cover the whole field of mining safety and mining welfare. Their devoted efforts in that work have resulted in developments of value and interest. Let us serve as the medium for their further distribution and broadcasting. All articles used are paid for at a fair rate of remuneration.

These Men gave their "Fourth" to the Red Cross

1. Some of the Jewell Ridge patriots.
2. And the coming generation at play.
3. Road their boys took for "Over There".

The Jewell Ridge Coal Corporation, of Jewell Ridge, Va., planned to hold a big Fourth of July celebration with a band playing and flags flying. But the miners thought it would be a waste of time and of money, and the United States wants both badly just now.

So they declared they would mine coal and thus help the boys on the battleships and transports. They gave all they made to the Red Cross and the company did the same. These men of the Virginian mountains, by their example, teach us all a splendid lesson.

COAL AGE

DISCUSSION BY READERS

Ventilating a Gassy Slope Mine

Letter No. 1—I have read the inquiry of "Mine Foreman," *Coal Age*, July 25, p. 191, asking for the best method of ventilating a mine opened by a slope pitching 6 per cent., when the seam is generating large quantities of gas. I heartily agree with the editorial suggestion made in the reply to this question, where it is stated that three main slopes should be driven on the full dip of the seam, the center one to be used as the main intake and haulage road, while the two side slopes serve for the main return air-courses on their respective sides of the mine.

Let me add, also, what the editor probably had in mind judging from his statement at the close, that each lift of cross-entries should be ventilated by a separate split of air to insure the best results. This should be done as early in the development of each split as possible, since it will render the entire circulation ascensional, as far as that is practicable.

In my opinion, this mine should be ventilated by a large centrifugal fan of ample size and capacity. Also, the return airways should be of good size and unobstructed. I fully endorse the suggestion, that the ventilation of the mine should be on the exhaust plan. Also, a duplicate fan should be installed for use in case of emergency, and each of these fans should be large enough to meet the requirements of the entire mine. This is important in order to avoid shutting down the mine in case of accident to the ventilator.

Air-Tight Stoppings of the First Importance

Another important feature in respect to maintaining adequate ventilation is that of building air-tight stoppings throughout the mine, especially the stoppings separating the main slope from the air-courses on either side. It must be remembered that the main intake current always seeks the line of least resistance, which occurs at every leaky stopping. The result is that, where leaky stoppings exist, a large volume of air may enter and leave the mine, while the circulation at the working face is deficient.

At the first point where the air current must be split, it will be necessary to ascertain whether the natural division of the air will meet the requirements, or whether it will be necessary to build a regulator, which every practical man knows must be placed in the short split, since it is this one that will take more than its share of air unless some means is used to prevent. Sometimes when both splits are of the same length, one will take more air than the other because it runs to the rise, causing a natural air column to form in the entry.

Where the natural division of the air meets the requirements, it is evident that such a condition will prove of great advantage, since a regulator always absorbs a certain proportion of the power. We learn that a regulator placed in an airway has the same effect as increasing the length of the airway which, of course, would mean an increase of power on the air. In the development of a large mine, these points, which appear small in themselves, will frequently cause a considerable increase in the power required for the proper ventilation of the mine.

Plymouth, Penn. JOSEPH R. THOMAS.

Blasting a Ditch in a Mine

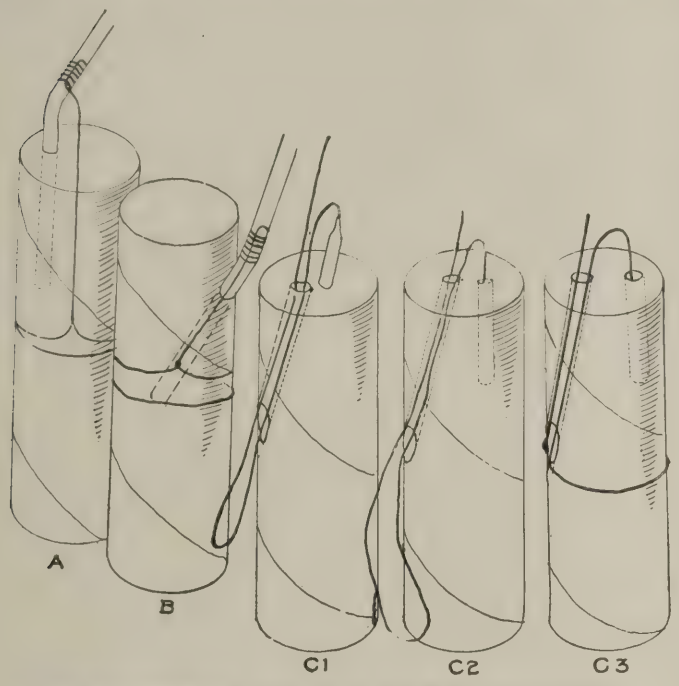
Letter No. 1—Kindly permit me to offer a suggestion in respect to the inquiry of George Smith, relating to blasting a ditch at the side of a slope road where 10 x 10-in. timber frames are set on 4 x 10-in. mudsills. It is stated that the ditch must be blasted in a hard bottom underlying the mudsills.

It is difficult to understand why the timber frames were set on mudsills, in this case, the bottom being hard. Usual mining practice is to employ mudsills only when the bottom is so soft that the legs would sink into the floor. However, accepting the proposition as it has been stated, I would suggest the following method of procedure:

Stand temporary posts under the collars of three or four sets, about 18 in. from the track, so as to allow the passage of the cars. Then take out the legs of these sets and the mudsills beneath them, which will give an opportunity to drill and blast the ditch at that point.

The holes for blasting should be drilled only to the depth required for drainage, and allowance made for a ditch 18 or 20 in. wide at the top. Care should be taken to drill the holes close together so that but a small amount of powder will be sufficient to break the rock. By this means, little or no damage will be done to the timbers.

Having completed the work under these four sets, the legs should be replaced and the temporary posts taken out. If the work has been properly planned, the mudsills can now be laid on the side of the ditch close to the rib. In the same manner another section of three or four sets can be treated and the ditch extended. I might say that where the ditch is shallow it may be practicable to use a point, made of octagon drill steel sharpened like a pick point. With this tool, it will often be possible to split up the rock, using wedges to assist the work. If this can be done it will not be necessary to use explosives, although the process will be much slower and increase the expense.



Let me say that, in my opinion, the ditch is much to be preferred to the siphon or pipe line suggested in the reply to this inquiry. It is true that the ditch would have to be cleaned, from time to time, but it would give better service and prove more permanent as a means of draining the slope, which is of the utmost importance when this is the main haulage road of the mine.

Cassidy, B. C., Canada. J. W. P.

Priming a Cartridge

Letter No. 1—I examined carefully the methods described by William Crocker, *Coal Age*, Aug. 1, p. 203, and H. J. Broughton, page 214 of the same issue, in regard to priming a cartridge. While I can agree with much that has been said by these two contributors, I would like to present the methods I have employed for this purpose, in my own work, during 25 years of practice in the blasting of rock tunnels and slopes and sinking shafts. These methods have always proved successful.

The accompanying sketch shows three arrangements, *A*, *B*, *C*, that I have employed at different times, in

SECURING THE CAP IN A PRIMER CARTRIDGE

blasting with the ordinary tape fuse, having a detonating cap crimped on the end, or when using electric detonators. The first two methods can be used in either case, but the last method is designed for electric fuse only. They are described as follows:

In the first method shown at *A*, a hole is punched in the center of the top of the cartridge, by means of a small wooden stick slightly tapered and rounded at the end. The electric detonator or the ordinary tape fuse with a blasting cap crimped on the end is inserted in this hole. As shown in the figure, the cap is made secure in the cartridge by a string tied to the fuse an inch or two above where it enters the cartridge, the other end of the string being made fast around the cartridge a short distance below the top. This prevents the strain of the fuse coming on the cap and dragging it out of the cartridge.

In the second method, as shown at *B*, the hole is punched in one side of the cartridge, running diagonally toward its center. The electric detonator or the ordinary tape fuse with cap is inserted in this hole and made secure with a string, in the same manner as described in the first method. In either of these methods, when the ordinary tape fuse is used, care must be taken that not more than ¼ in. of the fuse enters the cap, in which case there would be danger of the burning fuse igniting the dynamite, before the cap is detonated, which might prevent the detonation of the cartridge or lessen its force.

The third method, which applies to electric exploders only, is illustrated by three sketches, showing three stages of the operation. In the first stage shown at *C1*, a hole is punched near the center of the top of the cartridge and extends diagonally downward through one side. The lead wires of the fuse are now doubled back on themselves, about 18 in. from the cap. The double wire is inserted through the top of the cartridge and passed out through the side, forming a loop.

In the second stage, another hole is punched in the top of the cartridge about ½ in. from the first hole and the cap inserted into this hole, as shown at *C2*, in the figure. The third and last stage completes the operation by passing the loop formed in the wires around the cartridge and drawing them tight. In this manner the strain of the wires is prevented from coming on the cap and dislodging it from the cartridge.

Charging and Tamping the Hole

The charge and primer are now carefully inserted in the borehole and tamped with damp clay or other loose material gathered from the road, taking care to use only material that will not burn. "Bug dust" or the cuttings of machines must never be used for tamping. In any event, it is well to use a small plug of wet clay and press this gently down on the top of the primer. Then tamp gently for 8 or 10 in., using more force as the tamping proceeds to the mouth of the hole.

In closing, permit me to say that, in all my experience of 25 years, I have never heard of leaving an air space between the charge and its tamping, as suggested by Mr. Broughton and explained on page 216. In order to secure the best results in blasting, the charge should be packed in the hole so closely that no air spaces remain, which lessen the effectiveness of the expanding gaseous products. This would act in the same manner as clearance in a compressor cylinder acts to destroy the efficiency of the compressor. The firmer the tamping, the greater will be the execution of the explosive. Care must be taken not to disturb the detonator fixed in the primer when starting to tamp the hole.

Wilkes-Barre, Penn. J. P. G.

Safety in Shotfiring in Mines

Letter No. 7—To my mind, the most important feature, in connection with securing a maximum safety in the firing of shots in coal mining, is the use of electricity for that purpose. Employers of labor are recognizing, now more than ever, that it pays to protect the lives and health of their employees. It is almost impossible to step into any industrial plant of any size, without being confronted with the sign "Safety First."

In respect to safety, the method of firing shots by electricity possesses the greatest advantage over other methods. It has occurred to me that a brief description of the methods we have employed in our mines in blasting the coal would be of interest. It is well known that the coal seams of Franklin County, in this state, produce a good deal of gas. On this account, the use of black powder gave place to permissible powders long ago.

A customary charge is four sticks of the powder, although occasionally a miner will charge five sticks in a single hole. A sharp stick is used to make a hole in one of the cartridges, and a percussion cap is inserted to explode the charge. Most of the miners are using cotton-tape fuse to explode this cap, and I am only aware of one company in the county where the shots in their mines are fired by electricity.

The coal is all cut by machines, the fine cuttings and dust being loaded into a car and hauled out of the mine. According to agreement, the coal cut in each place is properly snubbed before a shot is fired in the place. The width of the room is 26 ft. Three shots are fired in each room, one center and two rib shots. The center shot is always fired first, which gives the rib shots a better chance to work.

Electric Firing in Illinois Mines

Where electric fuses are used in firing, the lead wires are 8 ft. long, which permits the ends of the wires to hang out of the hole far enough to attach the firing cable. The work of preparing and charging the shots is performed by the miners but all shots are fired by competent shotfirers after the men have left the mine.

When firing the shots, the shotfirer leaves his battery in a crosscut on the entry and drags the cable after him to the face where the shots are to be fired. The cable is of the twin type prepared especially for the purpose. The shotfirer scrapes the ends of the wires bright and, likewise, the ends of the lead wires, attaching them, in turn, to the wires of the firing cable. Having done this, he returns and connects the other ends of the cable wires with the poles of the battery.

Use and Care of Portable Hand Batteries

In the mine where I was employed there were six shotfirers, who did all the shooting for 375 or 400 loaders. The battery used was of small size, about a 6-in. cube, weighing 8 lb. The armature of this battery is operated by a spring, which must be wound up, and is held by a catch until released by pushing a button when the shot is to be fired. The battery is strong enough to explode four shots at one time if required, but care is needed to keep it in good condition. It must not be left in the mine where it would be injured by dampness and cause much trouble by frequently failing to explode the shots.

From time to time, the batteries used in blasting must be overhauled and a little oil applied to the bearings; loose connections should be tightened and the brushes cleaned and sandpapered. With proper care a battery will give good service for a long time. Some of the batteries, at the mines of the Old Ben Coal Corporation, have been in use five years, others for three years, and their use has never caused an accident. When it is considered that the No. 8 and No. 9 mines of this company, at West Frankfort, are hoisting between 8000 and 9000 tons of coal a day, some idea will be formed of the number of shots that are fired in these mines.

Briefly enumerated, the advantages of the electric firing system are: (1) The shotfirer is always in a safe place when the shot goes off. (2) There is no risk from a short fuse. (3) A possible fire started by the explosion of a shot is always detected by the shotfirer, before he leaves the place, which is not the case when the firing is done by fuse. I recall two instances when, as shotfirer, I discovered that the shots had ignited a gas feeder, which would have caused a disastrous fire if the burning gas had not been detected in time and extinguished.

SHOTFIRER.

West Frankfort, Ill.

Squibs vs. Electric Fuse

Letter No. 1—In response to the invitation to discuss the relative safety of single- and double-tape fuse, squibs, electric fuse, and electric detonators, for blasting coal, given in the reply to the inquiry by "Miner," *Coal Age*, July 20, p. 145, let me say that electric fuses and detonators are much the safest to be used, in my opinion.

My experience, derived largely in the old country, convinces me that there is greater safety in the use of any electric appliance, in place of the best quality of tape fuse, for the firing of shots in coal mining. If permitted, I will recite one or two instances to illustrate this point. In the first instance, 2 ft. of double-tape fuse continued to burn for 45 min. before setting off the charge, and in the second instance 2 hours.

Danger of Firing Shots with Tape Fuse

We were driving an incline in a 2-ft. seam of coal and lifting, on the average, 5 ft. of bottom. The explosive used was gelatin dynamite. We had encountered a large boulder of unusual hardness. With considerable effort, however, the leading miner succeeded in making a small pocket on the top of the boulder, in which he placed 150 g. (5¼ oz.) of gelatin dynamite primed with a detonating cap attached to the end of a 2-ft. length of double-tape fuse. The charge was covered with a handful of fireclay and the fuse ignited, after which we retired for lunch.

A half hour later the charge had not exploded. At that time, the foreman happened to come around and started down the incline. Believing that the fuse had gone out and fearing to warn the foreman of his possible danger, we allowed him to proceed. He had but just returned, a few minutes later, when the shot went off, much to our surprise and that of the foreman, who ordered us to report to the office that night. The foreman was so overcome by the thought of his narrow escape, that he could scarcely speak.

Another instance occurred when working on the night shift and packing a room with refuse slate and rock. A large rock had to be blasted, and a charge of 700 g. (1½ lb.) was used for that purpose. To ignite the charge the usual 2-ft. length of fuse was used. We listened in vain for the shot to go off.

Having in mind the mistakes of others in returning to a blast before it exploded, we waited a long time and then decided to put up some timbers in an adjoining place and not return to the shot. The result was that two hours later we heard the shot go off. Many accidents have come to my knowledge, caused by men returning to investigate a misfire, and practically all of these occurred in the use of a good quality of double-tape fuse.

Speaking of squibs, there are two general kinds used in the old country. First, there was what my friend

has called the "red spitter." It was the usual form of rocket squib, having a sulphur match for its ignition. This squib threw a shower of sparks into the air when the match reached the powder, and was dangerous to use in the presence of gas. What we called the "gas squib" had a match so impregnated that no flame was produced. This form was considered safe for use in gas.

In the use of tape fuse, I recall that a special igniter was employed, which consisted of a paper cartridge placed on the end of the fuse and capped with copper. Inside the cartridge was a small friction cap that produced the spark and ignited the sulphur with which it was in contact. The friction cap was exploded by a small key at the end of the cartridge. The sulphur fumes produced showed that ignition had taken place, but no sparks appeared outside the hole. The device did not prevent misfires, but as these cartridges were only carried by the shotfirers they were responsible for their use.

Let me repeat, in closing, that the safest of all means of firing shots is by the use of electricity. By means of the electric fuse, a charge of black powder can be ignited at its center, which greatly increases the execution, the charge being far more effective than when it is ignited at the top of the powder as when squibs are used. Even the best quality of triple-tape fuse will spit fire and ignite the top of the powder when the fuse has been extended to the center of the charge. Also, electric detonators do not need to be crimped, as is necessary when placing a detonating cap on the end of a fuse.

GASTON LIBIEZ.

Cedar Point, Ill.

[There appears to be some confusion in the terms applied to the different types of electric exploders. What is generally termed an "electric detonator," as has already been explained, consists of a copper cap containing a charge of high explosive, which is ignited either by an electric spark or by the heating of a platinum-wire bridge connecting the terminals of two copper wires that pass into and are secured in the cap.

The low-tension exploder uses the wire bridge to ignite the fulminate that explodes the charge, while in the high-tension exploder the fulminate is ignited by the spark passing between the wire terminals. The term "electric squib" is sometimes wrongly applied to the electric fuse, in which a paper cap is used filled with an explosive capable of igniting the charge, but causing no detonation.—Editor.]

The Miner and His Pleasure

Letter No. 1—Trusting I may be granted the privilege of explaining a statement made in my letter on "The Mining Situation," *Coal Age*, June 29, p. 1208, regarding miners owning and using automobiles, I desire to say that, in speaking of the large number of automobiles driven by miners and their frequent visits to other mining camps and towns, it was not my intention to question the right of a miner to own and operate an auto. That thought did not enter my mind.

I have been a miner, myself, long enough to know that he needs all the pleasure he can get. If he can find his pleasure in a car and has the money to buy one, no one has a better right to own and use an auto than the man who toils beneath the ground. Far be it from me to take from the miner any of the few enjoyments he has in life.

My reference to the autoing of miners was intended to emphasize the great need of increasing the production of coal at this time. My contention was then and is now that the miner should not allow pleasure to interfere with his regular work in the mine. In the present crisis, loyalty demands that pleasure must give place to work, and this does not apply to the miner alone, but to every man connected with the coal industry whether he be mine official or miner.

No one will deny that the need of an increased production of coal is pressing. It must be apparent to every observer that much time is lost by mine workers absenting themselves from the mine instead of sticking close to their work. To overcome this evil, I suggested the employment of a truant officer to hunt up men who are out of their places and ascertain the reasons for their absence. It was the best suggestion I had to make and it was my hope that others would follow with a better one. The plan is not original with me, as I have seen it tried where it worked successfully.

Result of Not Enforcing Penalty Ruling

When the ruling was first made of imposing a penalty of $1 for each day a miner was out of his place, the money to be paid to the Red Cross, we understood that it would be enforced and notices were posted to that effect. The result was that little time was lost by the miners that month. When it developed, however, as it did later, that the fines were not collected, miners again laid off and did not work regularly every day the mine was running.

Before closing, let me refer to the exception taken by Fred Hicks, in his letter, July 20, p. 144, to my statement that 90 per cent. of our men are foreign born and many of them could not read, so that all they know is what they hear. Mr. Hicks claims that 95 per cent. of the men working in the anthracite region can both read and write. I regret that such is not the case in our own locality, and am certain that my former statement is well within the mark.

It is not the fault of a foreigner that he cannot understand the English language and is unable to read or write the same, it is rather his misfortune. I have the utmost sympathy and respect for this class of workers in our mines, as many will testify who have worked for me.

However, as I remarked before, it is hard to make these men understand the seriousness of the present situation. Perhaps we are more to blame than they, for this failure on their part. There has been, however, a great change in this respect. Efforts are now being made to educate our foreign workers, and the mine boss or superintendent who does not use these men right and give them all the assistance they need is not wanted by the best companies. One of the most urgent duties of the mine foreman, today, is the education of his men, especially the foreign born, to understand what is wanted of them and to instill the principles of loyalty and true citizenship in the mind of every worker.

THOMAS HOGARTH.

Coal Run Mines, McIntyre, Penn.

INQUIRIES OF GENERAL INTEREST

Loss in Storage of Anthracite

Can you give any data, or say where to find them, regarding the loss in the storage of anthracite? Is there any diminution in weight when the coal has been dumped in a pile and allowed to remain, say a year before being used? I refer only to the natural and unavoidable shrinkage due to dusting, loss in handling several times and weathering. This information is of particular interest at present and will be greatly appreciated.

New York City. H. M. D.

The chief loss in the storage of anthracite in open piles is the loss by breakage, resulting in the degredation of the several sizes and the consequent depreciation in market value of the aggregate. As is well known, what are called the "prepared sizes" of anthracite; namely, broken, egg, stove and chestnut, command a higher price in the market than the smaller sizes of steam coal, which include pea, buckwheat, rice and barley.

Because of the breakage due to handling, the aggregate weight of the prepared sizes is decreased and that of the smaller sizes increased, in storage. The loss of weight, due to weathering, is practically inappreciable, in a limited period of storage of anthracite, as has been shown in the clean-up of large storage piles of this coal.

In an interesting and valuable paper prepared by R. V. Norris, consulting engineer, Wilkes-Barre, Penn., and read before the Wilkes-Barre meeting of the American Institute of Mining Engineers, June, 1911, it is shown that the depreciation in market value of anthracite stored in piles, aggregates, for all sizes, 5.36c. per ton. In his paper Mr. Norris gives the following table based on 1,000,000 tons of assumed quantities of egg, stove, nut and pea, stored on the Dodge system of large open piles:

Size	Original Quantity, Tons	Price per Ton	Original Value	Quantity Shipped, Tons	Price per Ton	Final Value
Egg	350,000	$5.00	$1,750,000	300,300	$5.00	$1,501,500.00
Stove	200,000	5.00	1,000,000	219,450	5.00	1,097,250.00
Nut	200,000	5.00	1,000,000	210,480	5.00	1,052,400.00
Pea	250,000	3.25	812,500	253,240	3.25	823,030.00
Buckwheat	.....	.....	.....	7,775	2.50	19,437.50
Rice, Barley	.....	.....	.....	8,755	1.75	15,321.25
Totals	1,000,000	.....	$4,562,500	1,000,000	.....	$4,508,938.75

Loss, $53,561.25, or 5.36c. per ton.

In the same paper, Mr. Norris shows that the loss by breakage of the coal when stored in bins or pockets, is far greater than when stored in open piles. In an estimate based on 1,000,000 tons of assumed quantities of broken, egg, stove, nut and pea, he shows that the depreciation in market value was found to reach 54.5c. per ton. The following table, presented by Mr. Norris, was prepared from several tests, although not representing average conditions, owing to the pockets not being filled in any instance, thus causing a greater drop and somewhat increasing the average breakage above what would occur when the pockets are completely filled:

Size	Original Quantity, Tons	Price per Ton	Original Value	Quantity Shipped, Tons	Price per Ton	Final Value
Broken	130,000	$4.75	$617,000	96,040	$4.75	$456,190.00
Egg	225,000	5.00	1,125,000	191,770	5.00	958,850.00
Stove	195,000	5.00	975,000	192,410	5.00	962,050.00
Nut	200,000	5.00	1,000,000	215,040	5.00	1,075,200.00
Pea	250,000	3.25	812,500	248,630	3.25	808,047.50
Buckwheat	.....	.....	.....	35,515	2.50	88,787.50
Rice, Barley	.....	.....	.....	20,595	1.75	36,041.25
Totals	1,000,000	.....	$4,530,000	1,000,000	.....	$3,985,166.25

Loss: $544,833.75, or 54.5c. per ton.

Mr. Norris draws attention to the fact that the cost of handing each way, including labor, repairs to equipment and supplies, but making no allowance for taxes, interest on investment and depreciation, will vary greatly owing to periods of inactivity when fixed charges continue in force. The tabulation, however, is suggestive and valuable.

Natural Mine Ventilation

The following question asked in a recent examination has puzzled me and others. Can it be answered in two ways? A mine has two openings, one 150 ft. higher than the other, at the surface. The outside temperature being 60 deg. F. and the inside temperature 40 deg. F., in what direction will the current flow and why?

Shamokin, Penn. ASSISTANT FOREMAN.

The correspondent does not state whether the seam is flat or has an inclination and, in replying, it must be assumed that the temperature throughout the mine and the shafts is 40 deg. F. On this assumption, the air in the upper part of the deeper shaft would be cooler than the outside air. The upper 150 ft. of air column in the deep shaft would then outweigh the corresponding 150 ft. of atmospheric column above the shallow shaft, while the remaining shaft and atmospheric columns balance each other. The result is that a downcast current is formed in the deeper shaft and an upcast in the shallow shaft.

However, in practice, the pressure due to these air columns cannot be estimated on such assumed temperatures, since the temperature of the air entering the deeper downcast shaft will be greatly modified by reason of its higher temperature in the atmosphere before entering the shaft.

While the average temperature of the upcast air, in the shallow shaft, can be assumed as 40 deg. F., the average temperature of the downcast air in the deeper shaft will be somewhat higher, depending on the depth of the shaft. This will have the effect to reduce the effective air column producing the circulation. The problem is further modified by the fact that the second opening may be a drift, instead of a shallow shaft. This would reduce to a minimum the counteracting effect of the increase of temperature in the downcast air caused by the warm air entering that shaft.

EXAMINATION QUESTIONS

Mine Foremen's Examination, Shamokin, Penn., Apr. 23, 1918

(Selected Questions)

Ques.—What precautionary measures would you take with the abandoned portion of a mine in operation?

Ans.—The Anthracite Mine Law of Pennsylvania requires that all abandoned parts of a mine in operation shall be, as far as practicable, kept free from accumulations of dangerous gases and water, or the inspector of the district notified when it is found impracticable to do this. General practice has been to ventilate all abandoned portions with a sufficient air current to prevent the accumulation of gas, or to seal off such abandoned places by building air-tight stoppings. When abandoning any portion of a mine permanently, all track material and other equipment should be removed and timber withdrawn, for use in other places.

Ques.—In case of a squeeze occurring in a mine under your charge, at what stage of its progress would you consider yourself justified in stopping operations and withdrawing the workmen?

Ans.—When there is plain evidence that a squeeze has started in a certain section of the mine, safety would require that the men working at the face in that section should be withdrawn promptly and not permitted to return to their working places until the mine is again quiet. During the progress of a squeeze there is danger of loose pieces of slate or rock falling at the face. Sections of the roof that would otherwise be safe may suddenly be loosened and fall, during the progress of a squeeze. At such times, little warning is given by the falling roof. Only competent men should be employed to do what they can to arrest the progress of a squeeze by drawing timber in certain standing areas that have been abandoned and working back pillars in other sections of the mine that are as yet unaffected by the squeeze. Every reasonable effort should be made to start a heavy roof fall, in adjoining sections, so as to relieve the pressure on the pillars in those sections of the mine affected by the squeeze.

Ques.—When the water gage is 1.85 of an inch, what pressure per square foot does it indicate?

Ans.—Each inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft. in the airway at the point where the gage reading is taken. A water gage of 1.85 in., therefore, corresponds to a pressure of $1.85 \times 5.2 = 9.62$ lb. per sq.ft.

Ques.—In driving a gangway in the Mammoth vein, the coal being of a bursting nature, timbers are set 5 ft. apart; what precaution would you take in making room for the next set of timber?

Ans.—Besides setting the usual temporary posts for the protection of timbermen when putting the next timber-frame in place, means should be taken to support the side pressure on the ribs and prevent the bursting out of the coal, until the required lagging can be placed behind the timbers. For this purpose forepoling or a system of temporary lagging should be employed. Where the roof is frail it should also be supported by forepoling.

Ques.—What method of ventilation reduces the danger of explosion, also friction?

Ans.—Splitting the air current as often and as quickly as the development of the entries will warrant affords a better control of the ventilation in each section of the mine, reduces the velocity of the air at the working face, provides fresh air in each section and conducts the gases generated therein directly into the return current, thereby reducing the liability to an explosion. The reduced velocity, also, greatly lessens the friction.

Ques.—The anemometer makes 275 r.p.m., in an airway that measures 7 ft. 4 in. at the top, 11 ft. 11 in. at the bottom, and is 7 ft. 6 in. high; what quantity of air is passing?

Ans.—The average width of this airway is the half-sum of the top and bottom widths, which is 9 ft. 7½ in., or 9.625 ft. The sectional area of the airway is, therefore, $9.625 \times 7.5 =$ say 72 sq.ft. Taking the speed of the anemometer indicated by the dial, as the average velocity of the air current, the quantity of air passing in this airway is $72 \times 275 = 19{,}800$ cu.ft. per min.

Ques.—Which should be the largest, the inlet or the outlet airway, in a mine, and why?

Ans.—Considering the ventilation only, the return airway of the mine should have a larger sectional area than the intake, for several reasons: (1) There is always more or less gas generated in a mine, which increases the volume of the return air current. (2) Almost without exception, the temperature of the return current is higher than that of the intake, which expands the volume of the return air, making it larger than that of the intake current. (3) Since air flows from a point of higher pressure to a point of lower pressure, it follows that the return current is subject to a less pressure than that of the intake. This reduction of pressure on the return airway acts to increase the volume on the return current, which is true whether the fan is blowing or exhausting.

It may be important to consider other practical questions relating to the working of the mine, in deciding the relative size of the intake and return airways. For example, in a gaseous mine where the haulage is generally performed on the intake airway and men are compelled to travel on this road in passing in and out of the mine, safety requires that a good clearance should be provided at the side of the track to enable the men to pass the cars with safety. This consideration may require a larger sectional area on the intake than is necessary in the return airway. Also, the movement of the cars, and especially that of the loaded trip passing out of the mine, offers considerable obstruction to the air current, and this consideration, again, may require a larger sectional area for the intake airway.

COAL AND COKE NEWS

What Happened in July

[The bracketed figures in the text refer to pages in the present volume, reference to which will give fuller information regarding the matters discussed in the item to which the bracketed figures are attached.]

July 1—New prices are set for coal delivered in Cook County, Ill. (Chicago)—John S. Wentz, one of the principal stockholders in the Wentz Coal and Iron Co., Wentz Corporation, Upper Lehigh Coal Co., Maryd Coal Co., Midvalley Coal Co., and J. S. Wentz Coal Co. dies at Philadelphia [84]—Strike ends at Tuxhorn mine, Springfield, Ill., where negroes and foreigners had clashed [71].

July 2—Henry F. Shoemaker, a leading coal operator in Ohio dies in New York City—The Fuel Administration adds 25 inspectors to its staff to watch the preparation of bunker coal [22].

July 3—Viscount Rhondda, formerly David A. Thomas, British Food Controller dies. Lord Rhondda, as D. A. Thomas, was closely bound up with the development of the South Wales coal fields and it was expected at one time that he would become a large owner of West Virginia coal lands and collieries [66]—Fuel Administration prohibits the distribution of gas coal from docks on Lake Michigan or Lake Superior without permission, except to persons engaged in the manufacture of gas or in the operation of byproduct plants—The Fuel Administration issues a regulation reducing the coal supply of the breweries to 50 per cent. of that used in the past three calendar years [67]—Eugene C. Eppley appointed head of hotel section of the Conservation Bureau of the United States Fuel Administration [67].

July 4—Jewell Ridge Coal Corporation and mine workers donate to American Red Cross all the coal mined on this day [70]—Supply of cars to the Huntingdon and Broad Top R.R. is reduced 50 per cent.

July 5—Fuel Administration defines "modified mine run"—mine run from which large sizes are removed—and provides prices for same ranging from 40 to 90 per cent. of the difference in price between run of mine and screened coal above the price of the former [67]—Telegrams sent to 750 retailers threatening to cut off coal supply if reports were not furnished weekly [68, 178]—Inquiry by Board into the operation of high-cost mines in Central Pennsylvania.

July 6—Anthracite Tridistrict Board asks for a higher wage scale to meet increased cost of living [79]—Agreement to compensate the owners of undermined and wrecked buildings is made in Wilkes-Barre, Penn., binding certain coal companies and not binding the city. It provides compensation to owners of properties on the assessed valuation of the property up to $5000, and provides a $100,000 compensation fund. Owners of properties undermined are to be notified, to be compensated in full for moving expenses and to be remunerated in full for rental of new premises—Department of Labor refuses to permit the importation of Mexican labor to mines in New Mexico [70]—New classification for Ohio is issued dividing state into eight producing districts and providing rates for each division [67]—Fuel Administration orders that the amount of coal furnished to domestic users shall not exceed quantity necessary to heat every room up to 68 deg. Fahr. using scientific and conservational methods [68].

July 7—The War Labor Policies Board announces the establishment of Community Labor Boards to mobilize labor [70, 71].

July 8—Bill reported to Senate forbidding the manufacture of beer, wine and other intoxicating malt or vinous liquors for beverage purposes after Nov. 1 and all sale of such liquors or of distilled spirits after Dec. 31 except for export—Department of Labor limits work of United States Employment Service to manufacturers of war material employing over 100 workers and declares itself willing to permit the engaging of men where service is not directly or indirectly solicited [71]—Members of the Anthracite Conciliation Board directs that in case of the funeral of the victim of a mine accident the company owning the mine shall pay an additional $150 to the compensation provided by the compensation law provided that no men lay idle on that day except the members of the immediate family and six other men, the abstention of whom will not cripple the colliery. The six men will be chosen by the mine foreman and grievance committee. Their wages will be paid by the company [181, 227]—Order is issued by Fuel Administration fixing prices of crushed and screened coke and breeze from byproduct and beehive ovens, on beehive coke in Utah and on gas coke [68]—United States Fuel Administration sets prices for charcoal [68]—Furnace Run tipple and retarding conveyor of the Allegheny River Mining Co., near Kittanning, Penn., is burned down [148]—Battery of 80 Koppers byproduct ovens is charged for the first time by Bethlehem Steel Co., Steelton, Penn. [193].

July 10—Thirteen men burned in an explosion of gas at the Lackawanna colliery of the Delaware and Hudson Co. [148]—Preferential supply of coal cars to mines producing railroad fuel is discontinued—U. S. Fuel Administration announces that brewers can only count on receiving enough coal to complete the manufacture of beer from materials now in process of manufacture [134].

July 11—A. H. Smith, Regional Director of Railroads, issues order to speed railroad coal cars declaring that production had declined since June 15 owing to decreased car supply [133].

July 12—The National Coal Association with a membership producing annually 400,000 tons of bituminous coal declares in favor of immediate prohibition [136]—James B. Neale, Director of Production, U. S. Fuel Administration, addresses coal operators at Fairmont, W. Va., urging that operators and directors of companies spend their time at the mines speeding up production [229]—Organization meeting of Northern West Virginia Coal Operators Association held at Fairmont in which operators in an area embracing 12½ counties participated [147]—Thomas R. Brown, administrative engineer for Fuel Administration announces that a saving of coal equal to 81,000 tons annually has been effected in Pittsburgh plants by efficiency methods. A national saving of 25,000,000 to 30,000,000 tons is forecast in the 250,000 industrial plants of the country. One firm had a plant with only 59 per cent. efficiency.

July 13—Fuel Administration prescribes that country clubs may without a permit use wood or peat if railroad services are not utilized, but must obtain permits for the use of any other fuel [133]—Production of bituminous coal in the week just ended reaches 13,243,000 tons, the largest weekly production thus far attained in this or any year [180, 185, 196]—Harleigh-Brookwood coal breaker near Hazelton, Penn., is burned down [193].

July 16—Greenwood Colliery of Delaware & Hudson Co. is closed by a strike for higher pay to miners. (Strike ends on July 20) [180]—G. B. Markle Coal Co. puts its new breaker at Oakdale in operation [193]—Fanhouse of Lehigh & Wilkes Barre Coal Co. at Tresckow destroyed by fire [193].

July 17—John W. Moore, of Columbus, Ohio, has his distributor's license revoked, and the Elk Coal Co. doing business illegally under his license is required to refund commissions collected by it upon transactions carried on under the license issued to J. W. Moore [178]—Explosion of powder magazine of Black Brothers' Coal Co., Blackfield, Penn., kills one man and injures a dozen others [194].

July 18—Fuel Administration prohibits all persons owning or operating a dock on Lake Michigan or Lake Superior from selling, shipping, delivering, or distributing smokeless coal received at any such dock from the New River, Pocahontas, Tug River and other low-volatile smokeless coal fields for any other purpose than making illuminating gas, byproduct coke or coal briquettes or for special purposes as may be designated by the Fuel Administration under special permits—Fuel Administration expresses disapproval of carnivals and like gaieties in coal-mining regions [160, 276]—Coal cut off 70 coal dealers who were remiss in filing weekly reports [68, 178].

July 19—War Labor Policies Board announces that the Department of Labor will enforce a ruling that no contractor shall directly or indirectly employ children under 14 years in the performance of a contract for the Government nor shall he permit any child between 14 and 16 years to work more than 8 hours in any one day, more than 6 days in any one week or before 6 a.m. or after 7 p.m.—Fuel Administration provides that in Michigan, Ohio, Indiana and Illinois, where the allotment of anthracite for the current year has been materially curtailed, domestic anthracite sizes should be distributed first to those communities within the state which would experience the greatest inconvenience, difficulty and suffering by a failure of the supply expected [79]—Fuel Administration formulates orders for a reduction in outdoor lighting. This order is commonly referred to as the "Lightless Nights" order [178].

July 20—New order made by Fuel Administration revising former orders relative to required quality and grades of coal for bunkering steamships at Atlantic and Gulf ports [225].

July 21—German submarine sinks three coal barges and sets fire to the tug pulling them. This action took place near Cape Cod on returning from a trip with coal to Gloucester, Mass.

July 22—District draft appeal board at Scranton declares that mine clerks and stenographers are not essential workers [239, 227].

July 23—President Wilson by proclamation announces that on July 31 the Government will take over the telephones and telegraphs—President declares by proclamation that he will assume control of the Cape Cod canal July 25, and directs the Railroad Administration to operate it. It is the intention to safeguard the transit of coal to New England by the use of the canal which will be deepened to a depth of 25 ft.—D. W. Cooke, vice president, Erie R.R., appointed fuel administrator for New York State to replace Albert H. Wiggin, resigned—Fuel Administration appoints a Bureau of Labor, comprising John P. White and Rembrandt Peale, to administer coal mining labor disputes subject to the Administration and in accordance with a series of specified principles of practice [228]—Major Stuart, of Huntington, W. Va., in charge of recruiting in West Virginia, told not to take mine workers [229]—Strikes at 14 mines in Michigan for an increase of 10c. per ton in the rate for coal mining [277].

July 24—Fuel Administration announces that 150 coal miners at Mercer, Penn., have returned to work after several years of retirement [227]—Coal for lake transportation to be given preference over all coal except railroad coal, byproduct coal and coal for illuminating gas [226]—New "Lightless Nights" order of July 19 becomes operative [178].

July 25—Fuel Administration puts maximum price of domestic coke f.o.b. cars where produced at $1 less than maximum Government price for selected foundry coke f.o.b. cars at the same point [226]—Conference between representatives of Fuel Administration and the smokeless coal operators of West Virginia to adjust standard of prices [226]—Prices are set for coal at all Nova Scotia operations by C. A. Magrath, Fuel Controller of Canada.

July 26—Frank J. Hayes, president United Mine Workers of America, completes a tour of the anthracite region made for the purpose of speeding production—Fuel Administration appoints Roy A. Rainey, of New York, and David D. Bush, of Chicago, to the Production Bureau in charge of priorities in mine supplies to work in conjunction with War Industries Board [226].

July 29—Order in Council in Canada gives railroads the right to file increases in tariff rates of 20 per cent. in transatlantic traffic on Aug. 1, to come into effect Aug. 12, and to remain in force to close of war—Scranton surface Protective Association declares mine-cave agreement unacceptable—John R. Powell, pioneer "squib" manufacturer dies at Plymouth, Penn. [290].

July 30—New prices are made for wagon coal at mine and delivered in Pittsburgh, Penn. [274, 275].

Harrisburg, Penn.

Coal production in the Central Pennsylvania field for the week ending July 20 totalled 1,282,000 tons, 89,390 tons less than the estimated full-time tonnage for the mines reporting. The loss attributed to car shortage was 20,821 tons, and the loss due to labor shortage was 51,980 tons. The week's production was 78,000 tons less than the week before.

R. W. Gardner was appointed production manager of the United States Fuel Administration of the Pittsburgh district on Aug. 6, to fill the place made vacant by the resignation of O. A. Blackburn. Mr. Gardner says that steps will be taken whereby the production will be increased by 15 to 20 per cent. This will mean an added tonnage of 30 or 40 tons each day. He said: "We are planning to have a committee of six at each mine. Three of these men will be chosen by the operators and a like number by the miners. Each committee will report every week to the production manager. Thus we will be able to discover the shortcomings of either the men or their employees."

The coal operators have agreed to pay the salaries in the production manager's office. The Government will furnish the funds for the office rent and furniture.

Inspection of boiler on steam dredge taking coal from navigable streams of Pennsylvania is outside of the scope of the authority of the Department of Labor because such dredges have the status of other steam vessels navigating the streams of the State, holds Deputy Attorney General Emerson Collins.

Uniontown, Penn.

Step by step, the Connellsville coke region is being geared up to war-time efficiency. The last few weeks has seen several orders of a rather drastic nature promulgated by the Fuel Administration and compliance with those regulations has resulted in a steady although not extensive increase in production despite the prevalence of hot weather, which is ordinarily a factor to contend with on the coke yards. There was a discouraging slump in both the coal and coke output for the week of July 20, but for the week ending July 27 production again showed a marked increase, the coal output being 171,293 tons or a gain of 10,153 tons over the previous week and a gain of 29,169 tons over the corresponding week in June, while the coke output was given as 348,180 tons. These figures were issued from the local Fuel Administration office.

Meantime the elaborate and rather complicated labor supervising system is being rounded into shape and its effects are already felt. There is a noticeable tightening up of labor throughout the region, the personal letters directed by the Fuel Administration to labor slackers usually being sufficient to bring them into line. To add further to the effectiveness of that system there is now being considered the appointment of a production manager at every plant, whose business it will be to see that the men stay on the job.

There was little grumbling among the workers because coal company employees were not included in the recent 10 per cent. wage advance given certain munitions employees of the United States Steel Corporation. The men are now making more money than they ever made before in their lives and seem contented as far as wages go. A notable instance of big pay envelopes was at the Adelaide plant of the H. C. Frick Coke Co., where Joseph Malachick drew $158.34 last week for two weeks' work. His pay for the last four weeks was $300.96.

The maximum price fixed for screened coke by the U. S. Fuel Administration is considered favorable by the operators engaged in salvaging coke breeze from ash dumps, an industry which has reached some proportion in the Connellsville region. As applied to this region the order means that cleanly screened coke from ash dumps which can be used as domestic fuel can be sold at a maximum of $6 whether it is shipped for domestic use or not. If it is sized coke over ¾ in. it will bring a maximum of $7.30, and under ¾ in. a maximum of $5. The $6 price applies to all sizes mixed together if the coke is large enough for domestic use.

Charleston, W. Va.

Climatic conditions and a light car supply are believed to have had a marked effect on coal production in West Virginia this week. The supply in many districts seemed to be much lighter than usual, and this scarcity seemed to be more or less uniform throughout the state. Seeking for a cause for such a condition it was learned that districts in other states having fallen behind in their supply last month, an effort was now being made to help them catch up. The intense heat of last week has been such in all the coal fields that it was almost beyond human endurance, and consequently there was a marked decline in the number of men reporting for work.

Last week, laboring under high pressure to meet Government requirements, the mines of the Fairmont district produced coal in such quantities that it threatened a serious congestion at many division points on the Baltimore and Ohio Ry. During the current week, however, the supply has been exceedingly light. Monday the car supply in the Fairmont district was exceedingly small, being 1376 cars—something like 400 under requirements. On Tuesday cars were even more scarce, there being only 1051 in the region. Team back operators in the Fairmont region were hard hit by the issuance of an order prohibiting the shipment of coal loaded in box cars to New England points. As an order already in effect prohibits westbound shipments of the same nature, the snow-bird mines have only a limited field to which to ship. An effort is being made to have the new order changed or canceled, as production will be to some extent affected unless it is rescinded or altered.

Production in the Kanawha District underwent a slight decrease last week as compared with the last week in the month, the production for the week being 216,528 tons, a decrease of about 3500 as compared with the previous week, this decrease being due to labor shortage and to mine disabilities largely, though this week the car supply is only running about 80 per cent. of requirements. The present slight shortage is not regarded as being permanent.

Coal production in the Guyan field was brisk during July, more than a million tons being loaded. It is felt, however, that had the railroad service been a little better and had men remained steadily at work there would have been a production of at least 1,500,000 tons.

Production is being slowly increased in the Pocahontas and Tug River fields, but the operations in those regions have been hard put to get a sufficient number of men to man the mines there. However, since a recent production campaign waged in that district miners are applying themselves more assiduously to mining; and though the draft has made inroads on the industry, greater regularity in reporting for work has to some extent helped keep up and in fact increase production.

Fairmont, W. Va.

Final steps were taken here last Saturday to complete the organization of the Northern West Virginia Coal Operators' Association, begun at a large meeting held here about the middle of July.

In calling the meeting to order, R. B. Isner, chairman of the organization committee, designated C. H. Jenkins, of Fairmont, as temporary chairman and F. J. Patton as temporary secretary. As soon as the report of the organization committee had been submitted and the plan of organization ratified the board of directors chosen at the meeting unanimously elected C. H. Jenkins, formerly president of the Central West Virginia Association, as president of the new organization. R. B. Jane was elected vice president and C. J. Ryan treasurer.

As the appointment of A. B. Fleming, Jr., as director of production for Northern West Virginia had just been announced, Mr. Fleming was called upon. He told of his conference with J. B. Neale, director of production at Washington, and outlined what was hoped for in the way of production.

Temporary directors for the various subdistricts, elected at the July meeting, were made permanent directors as follows: Fairmont subdistrict—A. B. Fleming, Jr., A. C. Beeson, J. A. Clarke, Jr., Geo. E. Peddicord and C. H. Jenkins. Clarksburg subdistrict—A. L. White, D. Howard, J. M. Orr, C. J. Ryan and V. E. Goecke. Elkins subdistrict—E. D. Baker, A. C. Wadell, W. J. Williams, A. R. Miller and R. B. Isner. Morgantown subdistrict—S. D. Brady, B. M. Chaplin. Directors at large—J. M. Wolfe, of Fairmont; J. A. Jenkins, of Clarksburg, and E. Drennen, of Elkins.

Representing as it does a merger of four preëxisting associations, the new association is now said to be the largest association in the United States. The Central West Virginia was the third largest prior to the consolidation.

Herrin, Ill.

The tonnage of coal in the Williamson and Franklin field, as well as in the Harrisburg field, at mines depending upon the Central Illinois Public Service Co. for its supply of electricity, continues to show a loss of production on account of the inability of the service company to maintain current.

In the month of July the following record has been tabulated at Herrin, showing the number of times in the different days that the juice was off: July 2, off 2 times; July 3, off 5 times; July 5, off 5 times; July 10, off 3 times; July 11, off 5 times; July 15, off 4 times; July 16, off 4 times; July 17, off 6 times; July 18, off 1 time; July 22, off 5 times; July 23, off 11 times; July 24, off 1 time.

Not only are the operators vexed, but there is a growing dissatisfaction among the miners, machine men and others who work with electricity; and this may be one of the reasons why many men are leaving this field and going to mines not depending upon this current and to mines in other fields where their own current is produced locally.

Nanaimo, B. C.

The Jingle Pot mine, owned and operated by the Nanaimo and Vancouver Coal Co., which has been closed up on account of a fire in the workings for the last ten months, has been reopened again and will be in full operation in the course of two weeks, when the necessary repairs have been completed.

The Western Fuel Co.'s new shafts, at the Wakeisah farm, are being rushed down at top speed. W. H. Moore, the manager, expects to have from 200 to 300 tons of coal coming from those shafts by the end of the present year. The Harewood mine, recently opened up by the same company, is getting out a record tonnage, amounting to nearly 11,000 tons daily. Albert Rowbotton has been appointed tipple foreman at this mine in place of Mr. Davis.

The Grant mine, which is situated at Nanoose Bay and owned by a local company, is producing about 150 tons of coal a day. As this is a new mine, development work is being rushed as rapidly as possible. It is only a matter of a little more time when a handsome tonnage will be obtained from this colliery.

It is currently reported in the district that the Canadian Pacific Railway Co. has leased 960 acres of coal lands in Cedar district, where borings will be commenced in the near future for coal.

PENNSYLVANIA

Anthracite

Park View—Some people, upon arising on Aug. 3, found their war gardens had been swallowed up in mine caves. The heavy rains are thought to have caused a settling of the ground.

Freeland—The employees of the J. S. Wentz Coal Co., of Hazel Brook, will hereafter be allowed street carfare one way each day they report for work and the company will add 15c. for carfare per day to each man's earnings.

Bituminous

Horatio—After being idle for more than 22 years, the Old Berwind-White Coal Mining Co. mine is again on the job producing coal. The mine was known as "Horatio" No. 2, and is being operated now by the Anita Coal Co. shipping first-class coal in paying quantities. When the mine was abandoned coal was selling at so close a margin that no operator could afford to spend much time or money to overcome faults, rolls, etc. In addition the mine was a wet one and required considerable expense in pumping out the surplus water.

WEST VIRGINIA

Roderfield—New equipment is being added to the plant of the Fall River Pocahontas Collieries plant at this place, in addition to the construction of a number of houses for miners.

Huntington—A second substation is being installed by the Algoma Coal and Coke Company at its Algoma plant. New houses for the accommodation of miners are also being built.

Big Sandy—A number of improvements have been made to the plant of the Hampton Roads Colliery Company's Big Sandy plant, consisting of 30 stucco houses for miners, a club house and bath house. A new system of sewerage has also been installed.

Clarksburg—C. S. Elliott, of Clarksburg, has sold the valuable coal tract owned by himself and his brothers to Pittsburgh capitalists for $750,000. The field purchased is located near Fayette City, Penn., and it is understood development work will be begun at once.

Welch—Coal from the Cyrus and Kimball mines of the Kimball-Pocahontas Coal Co. will be run over the same tipple. This company is building more houses to accommodate additional miners. A new 15,000-gal. water tank is also under construction. The superintendent is Mike Barron.

Bluefield—The progress being made by the Solvay Collieries Co., of which W. P. Goodman is superintendent, at its Hemphill plant is such that the company will be able to begin shipping coal by Oct. 1. The capacity of the new plant will be 2000 tons a day. Thirty stucco houses are now under construction.

Keystone—New equipment is being added to the plant of the Eureka Coal and Coke Co., of which T. W. Chambers is superintendent at Eckman. The company is also building a number of new miners' houses. The Keystone Coal and Coke Co. is erecting an up-to-date steel tipple at its plant here, under the direction of W. W. Wood, superintendent. Forty new houses are also under construction.

Gary—Additional equipment is being installed at the Elbert No. 7 mine of the United States Coal and Coke Co., where 45 new miners' houses are also being built under the direction of W. P. Kearns, superintendent. A new steel tipple has been completed at the Elbert No. 8 mine of the same company, of which J. L. Sullivan is superintendent. A number of new miners' houses will be built at this plant. It is estimated that by the time all the improvements are completed the company will be able to ship 1500 tons of coal a day.

INDIANA

Brazil—Coal miners in the Brazil territory are pleased with the action of officials of the Pennsylvania R. R. in agreeing to place in service a miners' train between Harmony and Glen Ayr to carry miners to and from their work. The train was taken off the road two years ago.

ILLINOIS

Decatur—Decatur is two and one-half to three months ahead of ordinary summer seasons in putting in its coal supply. In other words, the situation for Aug. 10 is about the same that it would ordinarily be about Oct. 10. Some of the Decatur coal dealers have contrasted their daily business this year with their usual September and October business, stating that before the war July was a month which was dull beyond all extremes.

Nokomis—The Keller Coal Co. has resumed hoisting coal in its No. 10 mine after a shutdown of over two months. The closing of the mine was due to a fire which broke out in the underground workings of the mine early in May and raged fiercely for over a week and for a time threatened the destruction of the entire mine. The mine has a hoisting capacity of over 6000 tons per day and for a long time held the state record. Over 1200 men will be employed in this mine in the future.

Carlinville—The Standard Oil Co. has had to stop work on the sinking of mine No. 2 northeast of Carlinville on account of quicksand and water which were encountered when about 100 ft. down. The abandonment of the mine is said to be only temporary, as the company expects to continue the shaft as soon as it can secure the necessary material to make the working conditions safe. In the meantime the company has commenced work on the sinking of mine No. 3 on the same tract. It was not the intention of the company to sink mine No. 3 until mine No. 2 had been completed. Work on Mine No. 4 is progressing nicely, and it will be ready for operation by Oct. 1.

UTAH

Peerless—The Peerless Coal Co., whose mine is located here, is now shipping coal. The mine is equipped with modern machinery and is expected to produce 1000 tons of coal a day. The seam being worked is over 12 ft. thick. Other seams of coal on the property will be worked eventually.

Foreign News

Victoria, B. C.—Coal mine casualties in British Columbia for April, May and June of this year were only four as compared with 39 for the same three months in 1917, according to the quarterly statement of mine fatalities issued by the Provincial Department of Mines. For the first six months of the year the deaths were six for 1918 as compared with forty for 1917. Of these six all were killed underground, three by falling roof and rock, two by mine cars and one by falling timber.

Personals

James D. Simpson is now mining manager of the Berwind-White Coal Mining Co., with headquarters at Windber, Somerset County, Pennsylvania.

L. R. Bayer, formerly with the Bureau of Standards, has joined the organization of E. & T. Fairbanks & Co., scale manufacturers, St. Johnsbury, Vt.

Alan C. Dodson, of Bethlehem, Penn., has been appointed a member of a new committee recently formed by the Fuel Administration to aid in an intensive campaign to provide for an increased production of coal.

Robert Howard has resigned his position of state coal mine inspector of Utah to accept the superintendency of the Peerless Coal Co., which has a mine at Peerless, Utah, with general offices at Salt Lake City.

John E. Williams has resigned as state fuel administrator of Illinois. He is succeeded by Raymond E. Durham, who has been serving as fuel administrator of Cook County (Chicago). Mr. Durham is vice-president of the Chicago Savings Bank and Trust Co. and is a well known and influential business man of Chicago.

John Crawford, of Helper, Utah, has been appointed by the Industrial Commission of Utah to the position of state coal mine inspector. His appointment took effect Aug. 1. Mr. Crawford has been working in and around the mines of the State of Utah for the past 20 years and has held various positions from mine foreman to superintendent during that time.

Charles O'Neill, of Altoona, Penn., has been appointed manager of the Central Pennsylvania coal district by the Fuel Administration. Mr. O'Neill will have supervision over Westmoreland, Cambria, Armstrong, Huntingdon, Somerset, Elk, Tioga, Clinton, Jefferson, Indiana, Clearfield, Cameron, Bedford, Lycoming, Blair and Centre Counties. Mr. O'Neill is secretary of the Central Pennsylvania Coal Producers' Association.

Obituary

Julius E. Bierach, sales manager at Louisville, Ky., for the St. Bernard Coal Mining Co., has passed away. Mr. Bierach started with the company 30 years ago as a weigher, later he became a salesman, and finally sales manager. At the time of his death he was 54 years of age. Death was due to a complication of diseases, following an illness of a year, a considerable portion of which was spent at St. Anthony's hospital.

Frank M. D. Watkins, assistant general sales agent of the Shawmut Coal and Coke Co., died at his home in Binghamton, N. Y., July 21, following an operation. He was 40 years old and leaves a family. He had been with the company nearly ten years and was nominally attached to the office of the general sales agent in this city. A man of the finest character and high social attainments, he was also a leader in business and will be much missed everywhere he was known.

Fuel Saver and Smoke Consumer. L. D. West, Denver, Colo., 1,267,295. May 21, 1918. Filed June 12, 1917. Serial No. 174,319.

Furnace Grate. A. W. Bennis, Little Hulton, Bolton, England, 1,267,172. May 21, 1918. Filed Mar. 29, 1915. Serial No. 17,858.

Coal Pit for Locomotive Tender. E. G. Bartlett, Boston, Mass., 1,267,170. May 21, 1918. Filed Sept. 26, 1917. Serial No. 193,357.

Mining Apparatus. C. J. E. Waxbom, assignor to Jeffrey Manufacturing Co., Columbus, Ohio, 1,267,943. May 28, 1918. Filed Oct. 11, 1912. Serial No. 725,322.

Trade Catalogs

Nonpareil Insulating Brick for Furnaces and Ovens. Armstrong Cork and Insulation Co., Pittsburgh, Penn. Booklet, Pp. 4; 3½ x 6 in.; illustrated. Shows the necessity of properly insulating steam lines against loss of heat, and gives data to prove that Nonpareil insulating brick saves 60 to 75 per cent. of the heat ordinarily lost by conduction and radiation.

Catalog No. 33, May, 1918. Steel City Electric Co., Pittsburgh, Penn. Pp. 108; 6 x 9 in.; illustrated. First edition of a complete catalog covering this concern's standard materials. For convenience in ordering by telegraph a code is furnished. The catalog is indexed and cross-indexed, and should prove of service to the buyers and users of Steel City Electric Co. materials.

Motor-Operated Brakes for Alternating-Current Service. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Pp. 4; 8½ x 11 in.; illustrated. Points out the application and desirable operating features of these brakes. Two installation views are included—one showing the brake applied to a large mine hoist motor, and the other to a motor-driven elevator machine. Dimensions, engineering data and the formula for determining the retarding torque required for any brake installation are also given.

New Incorporations

Kane, Penn.—The Big Level Coal Co. Capital, $25,000. To mine for coal in the Kane district. Albion Bengston is the principal incorporator.

Adah, Penn.—The Lynch Creek Coal Co. Capital, $25,000. To develop coal properties in the Adah district. R. C. Schultz is the principal incorporator.

Fairchance, Penn.—The Zebley Coal Co. Capital, $12,000. To operate coal properties in the Fairchance district. Harry Zebley is the principal incorporator.

Van Ormer, Penn.—The Beacon Coal Co. Capital $50,000. To develop coal lands in the vicinity of Van Ormer. A. N. Arthur, Evansburg, is the principal incorporator.

Coeburn, Va.—The Twin City Coal Co. Capital, $90,000. To engage in the development of coal properties near Coeburn. J. P. Lay is president and C. O. Ramsey is secretary.

Charleston, W. Va.—The Liberty Coal Mining Co. Capital, $10,000. To develop coal properties in the Charleston fields. Incorporators: J. A. Thomas, B. M. Smith and J. V. Sullivan.

Tulsa, Okla.—The Gunther City Coal Mining Co. Capital, $150,000. To engage in coal mining operations in the Gunther City section. Incorporators: E. A. Vernon and A. C. Gunther.

Fort Worth, Tex.—The Bowie Coal Mines Co. Capital, $100,000. To operate coal properties in the vicinity of Bowie. Incorporators: A. H. Woodfin and J. Murrin, Fort Worth; and W. R. Potter, Bowie.

Industrial News

Hazard, Ky.—The Midland Mining Co. has recently filed notice of an increase in its capital from $100,000 to $150,000, to provide for expansion.

Knoxville, Tenn.—The Cross Mountain Coal Co. has filed notice of an increase in its capital from $400,000 to $500,000, to provide for business extensions.

Scranton, Penn.—The Scranton Coal Co. is planning for the opening of new veins at its properties in New County. The coal will be handled at the Pine Brook colliery.

Patton, Penn.—Fire, July 18, destroyed the coal tipple of the Pennsylvania Coal and Coke Co., with estimated loss of about $30,000. It is understood that the plant will be rebuilt.

Goodwater, Ala.—The Central Railroad of Georgia, Savannah, Ga., is considering plans for the construction of a new local concrete coal chute to have a capacity of approximately 300 tons.

Indianapolis, Ind.—Retail coal dealers will have preference over manufacturing plants which are not included in the priority list prepared by the War Industries Board at Washington.

Chattanooga, Tenn.—The White Oak Coal Co., which recently filed notice of a change

in its corporate name to the Christian Coal Co., has increased its capital from $10,000 to $50,000, to provide for expansion.

Beaver Brook, Penn.—The C. M. Dodson Coal Co. is planning for the installation of a quantity of new equipment at the coal breaker at its Beaver Brook colliery to increase the present capacity of the plant.

Harrisburg, Penn.—The Buckeye Coal Co. has secured permission from the State Department of Health for the construction of a new town in Greene County, including a water-supply system, sewage-disposal plant, sewerage system, and other work.

Birmingham, Ala.—The Eagle Coal Co., recently organized, is planning for the development of about 100 acres of property at Adger. The company will install a plant to provide a daily output of about 200 tons. J. C. Maben, Jr., is president.

Hazleton, Penn.—Anthracite production in the Lehigh field was reduced by approximately 40,000 tons due to the idleness of the mines caused by a fire at the substation of the Harwood Electric Co., which supplies power for operation, on July 30.

Pineville, Ky.—The Greasy Gap Coal Co., recently incorporated with a capital of $25,000, is planning for immediate work on the development of about 480 acres of coal properties in the Wheeler district. I. Glickman is president and manager and M. Euster is vice president.

Elkhurst, W. Va.—The Elkhurst Coal Mining Co., the Thompson Block Coal Co., the Big Block Coal Co., and the Foy Splint Co., operating in the Elkhurst district, are planning for the electrification of their properties, power to be furnished by the Hartland Power Company.

Corinth, W. Va.—The Freeport Coal Co., which recently filed notice of an increase in its capital from $25,000 to $100,000, is now developing about 325 acres of coal properties in the Corinth district, with daily output of 100 tons. The company is planning for increased operations.

Joliet, Ill.—The Elgin, Joliet & Eastern R. R. has awarded contracts to the Ogle Construction Co., 28 East Jackson Boulevard, Chicago, for the construction of new coaling stations, about 20 x 20 ft., at South Chicago, Ill., and Gary, Ind. The structures will cost about $25,000 each.

Baltimore, Md.—In connection with extensions in its terminal facilities at its Bayview Junction, Md., yards, the Baltimore & Ohio R. R. has awarded a contract to the Empire Engineering Co., Curtis Bay Junction, for extensions in its coal-handling equipment, to provide for increased capacity.

Fairmont, W. Va.—Development will be undertaken in South Fairmont by the South Fairmont Coal Co., which has been formed with a capital stock of $150,000, those principally interested in the company being John W. Poling, McLough, W. H. Spedden, Carl D. Springer and E. C. Frame, all of Fairmont.

Jefferson City, Mo.—A report from the Bureau of Mines and Mine Inspection shows that in the past 18 months there were 82 fatal and 58 nonfatal mine accidents in Missouri. The mine tax law produced $27,318 since the law became effective, while the total cost of mine inspection during the 18 months was $14,102.

New York, N. Y.—Statistics just made public, show that during the month of June, there were exported from the Port of New York 6761 tons of anthracite with a valuation of $43,991 and 6807 tons of bituminous, valued at $50,751. Of the anthracite 5278 tons were sent to Canada and of the bituminous 4428 tons went to Brazil.

Henderson, Ky.—The Uniontown Coal Co., recently incorporated with a capital of $100,000, has perfected its organization, and is planning for immediate work on the development of approximately 1500 acres of coal lands in the Henderson district, to have a capacity of 500 tons daily. Clarence O. Potter, of Nashville, Tenn., is president.

Dunkirk, N. Y.—In connection with extensive improvements at the Brooks plant of the American Locomotive Co., plans have been prepared for the construction of a large new coal trestle to provide for an increase in the coaling facilities. The entire work, which includes the erection of new shop buildings, boiler plant, etc., is estimated to cost $150,000.

Zeigler, Ill.—For the first time in its 15 years of existence the town of Zeigler, founded by Joseph Leiter after his spectacular plunge in wheat some years ago, has now secured a church. The Southern Illinois Baptists have started the erection of a building. This is the first church the town has had. It is one of the largest strictly coal-mining towns in southern Illinois.

Huntington, Ill.—C. B. Williams, fuel administrator of Huntington County, has gone into the coal fields of southern Indiana where he will buy a reserve of coal for next winter. Nine dealers in Huntington have pledged themselves to store five carloads each for such a purpose. City officials, at a meeting held with Mr. Williams, told him that the city was not in a position to maintain a municipal coal yard.

Bristol, Va.—The Floyd Elkhorn Consolidated Collieries, recently incorporated, will acquire the properties of the Floyd Elkhorn Coal Corporation and the Drift Coal Co. in this vicinity. The new organization plans to increase the output at the works, and will install considerable new equipment, including mining machinery, mine cars, etc. A new electric power plant is also planned. The work is estimated to cost $150,000.

St. Louis, Mo.—The city of St. Louis has renewed its contract for the city institutions with the St. Clair Coal and Mining Co. and will pay $2.30 f.o.b. mines per net ton for all lump and egg, and $2.05 for 2-in. screenings. The contract covers between 200,000 and 300,000 tons of coal and is for one year. This is Standard coal, with a freight rate to St. Louis of 95c. This price is about 10c. under the price paid last year.

Duquoin, Ill.—At the recent meeting of the state and Federal mine officials in connection with the rescue station work the course of instructions in helmet work was changed from twelve to eight lessons with 10 hours for oxygen work. The course in first aid was changed to eight lessons. After passing the examination for the Bureau of Mines, the student will be examined for a state certificate by the managers of the different rescue stations.

Cincinnati, Ohio—More than half a million bushels of Kanawha River coal was brought to Cincinnati recently by a fleet of towboats and barges on the crest of an artificial wave in the Ohio River, which was started at Government Dam No. 20. Seven towboats, with 82 barges, loaded lightly because of the low water which prevailed in spite of the artificial rise, came into the harbor. Each barge carried an average of 325 tons, making approximately 25,000 tons total.

Indianapolis, Ind.—Western Kentucky coal will not be moved into Indiana and Illinois. The fuel administrator held that such coal is no longer needed in Indiana and Illinois because of the large production of coal in these states. This coal will be moved, however, to the Cincinnati switching district. Horace H. Herr, of the Indiana state fuel administration, says that the order will affect only the west tier of Indiana counties and that eastern Kentucky coal can still come to Indiana.

Toledo, Ohio—Activity at the Toledo docks of the various coal-carrying railroads continued, according to the figures of loadings given out covering the week ending Aug. 3. The Hocking Valley docks during the week loaded 164,602 tons as compared with 172,906 tons the previous week. The total for the season is 2,000,000 tons. During the same week the Toledo & Ohio Central docks loaded 73,000 tons as compared with 57,740 tons the previous week, making a total of 940,000 tons for the season.

Indianapolis, Ind.—Fifty tons of coal have been piled on the pavilion at the north side of the Federal Building and approximately 400 tons more will be added. The coal will be stored for heating purposes next winter. About 1200 tons of coal are required to heat the Federal Building each year, and when it was found that there was not sufficient room for storage in the basement the custodian of the building ordered the outside pavilion used. The coal will be piled on all sides of the fountain in the center of the pavilion.

Nelsonville, Ohio—The Buckeye Coal and Railway Co. has secured between 200 and 300 new workers at its mines in the Hocking Valley field, because of the closing down of the large number of brick manufacturing plants in the Hocking Valley. The company readily saw the value of the additional labor and secured the operation of special trains to bring the men from their homes to the mines, where they were most needed. This move has greatly increased the output of the company, which owns or controls 59 operations in the Hocking Valley.

Indianapolis, Ind. — Indianapolis Coal dealers will not be permitted to charge their customers more than 50c. a ton for wheeling coal from the street to the basement of a house. The administrator's ruling provides that the dealer and purchaser shall arrange for the price to be paid for the delivery of coal in bags. The Retail Coal Merchants' Credit Association announced a charge of 75c. would be established for wheeling coal from curb to basement or coal shed, $1 for delivering coal in bags to the first floor of a house and $1.25 for delivery of coal in bags in the basement. Fuel Administrator Matin Rehfuss then made an order reducing the wheeling of all coal to 50c. a ton from street to coal depository.

Louisville, Ky.—Recently an order was issued by the Fuel Administration placing Jeffersonville and New Albany, Ind., across the river from Louisville, out of the zone for western Kentucky coal supplies. However, the matter was taken up with the higher officials, and on Aug. 5, Fielding L. Wilson, Clark County administrator at Jeffersonville, received notice from Evans Woolen, state administrator, to the effect that western Kentucky coal would be permitted to enter the two cities, which for years have depended on western kentucky coal. The dealers had booked heavy orders on the strength of earlier rulings under which Kentucky coal could enter the cities. A few years ago both Jeffersonville and New Albany used Pittsburgh River coal almost exclusively.

Indianapolis, Ind.—A campaign to bring about a saving of approximately 20 per cent. of the fuel used in industrial plants of Indiana will be started at once under the direction of Frank C. Wagner, administrative engineer for the state fuel administration. L. R. Clapp, of Washington, D. C., representing the Federal Fuel Administration, has been in Indianapolis recently to confer with Mr. Wagner concerning preliminary plans for the campaign. Questionnaires will be sent to all owners of factories and industrial plants in the state asking for complete information as to conditions of boilers and furnaces, and suggestions will be made by Mr. Wagner as to changes in equipment and methods which will tend to reduce the supply of coal required to operate the plants.

Columbus, Ohio.—To instill patriotism into Ohio coal miners a series of war meetings is being conducted in mining districts which are expected to result in an increased production and a better spirit of coöperation with the nation's program. One of these was held last week at Byesville, attended by several hundred miners. Besides rousing a more defined win-the-war feeling in the workmen, each miner solemnly pledged himself to increase his individual production three tons daily. Among the speakers were General Schneider of the United States Shipping Board, President John Moore, of the Ohio Mine Workers' Union, and Sergeant Charles Blank, a British soldier, who suffered several wounds in battle. His story and plea to the men that they do their best to win the war made a strong impression on the miners.

Terre Haute, Ind.—The production of 2,865,163 tons of coal in Indiana during the month of July established a new record for Indiana, the output being more than 300,000 tons greater than the June production. In spite of the increase of production in the state, the supply will not be greater than required. The Fuel Administrator of Indiana expressed the hope last March that Indiana mines would produce coal at the rate of thirty million tons annually. Production has now reached the rate of 34,000,000 tons a year. The estimate of the Fuel Administration was made at a time when Kentucky and Virginia coal could be shipped into Indiana, and it was not required that the southern peninsula of Michigan be supplied with Indiana coal. These changes have made it necessary for the Indiana production to be increased above the tonnage which the Fuel Administration expressed as its desire early in the year.

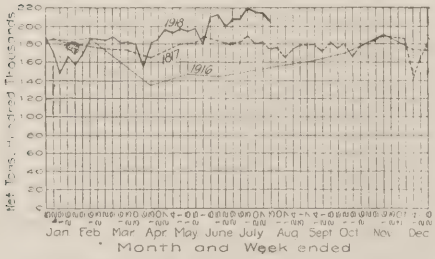
Lexington, Ky.—On account of the shortage of labor in the mines of the State of Kentucky production will this year fall below the 27,000,000 ton showing of last season, according to an estimate made by F. C. Horton, assistant inspector of mines. This shortage of labor, according to Mr. Horton, is due to increased developments and to the selective draft, which has greatly depleted the miners' ranks. Some of the mines which have a capacity production of 1200 to 1500 tons a day have only been able to load out 300 to 400 tons a day of late. If sufficient labor could be had, Mr. Horton estimates the production would easily be 35,000,000 tons this year, the increase over last year being made possible by new equipment that has been installed in the mines. A coal production of this amount would place Kentucky fourth among the coal producing states of the country. The possibilities of the coal fields of Kentucky after the war are declared unlimited. The known supply at present is enough to last for 600 years, while the extent of the deposits in the eastern parts of the state are unknown.

MARKET DEPARTMENT

Weekly Review

Intense Heat Somewhat Retards Both Production and Distribution—Present Needs Well Supplied, but Anxiety Is Felt for the Future

THE intense heat of the past week has exerted an influence more or less potent upon coal production and distribution. So great was the heat that it was difficult to keep men on the tipples or in the washeries and breakers. Many retail teamsters and car unloaders either worked only part time or refused to work at all. This naturally did much to retard both production and distribution. With all of the heat, however, which in many localities made a high record, the output of the country only fell off about 3 per cent.



Reports received from all over the country fail to reveal any shortage in present needs. Some regions have been able to accumulate surplus stocks in fair volume; others have not been able to build up any reserves whatever. That portion of the country lying roughly between the Rocky and Allegheny Mountains appears to be fairly well supplied with fuel. True, coal is being pushed to the Northwest via the Great Lakes with all possible dispatch, and some complaint is heard of a fuel shortage (especially in domestic coal) in Michigan; the greater part of this region is nevertheless well supplied. Near its center, in southern Illinois, certain grades of coal are selling below Government schedule.

Scarcity of coal seems to be most pronounced along either coast. New England, while admitting that coal is coming forward in adequate supply to meet immediate needs, is apprehensive as to the future; and the belief appears to be prevalent that not enough coal is being stocked, especially by railroads and large industries. Complaints of a similar nature are heard from other regions such as Baltimore, where industry has been kept going by emergency shipments.

The Pacific Coast also appears to be somewhat short of fuel. Although little scarcity is felt at present, anxiety is expressed for the future; and it is anticipated that other fuels such as wood must be employed in considerable quantities there during the winter.

COAL PRODUCTION

During the week ended Aug. 3 the output of bituminous coal not only decreased over 3 per cent. but recorded the third successive week of decreased production. Production of bituminous coal (including lignite and coal coked) during the current week is estimated at 12,422,000 net tons, a decrease compared with the week preceding of 398,000 net tons, but an increase over the same week of 1917 of 1,563,000 net tons or 14.3 per cent. The average production per working day during the week of Aug. 3 is estimated at 2,070,000 net tons as compared with 2,137,000 net tons during the week of July 27 and 1,810,000 net tons during the week of Aug. 3, 1917. Shipments during the past week decreased from all districts with exception of Cumberland-Piedmont and Somerset, Tennessee and Kentucky and Iowa, Texas and the Southwest States. The increase from the Cumberland-Piedmont district was 7 per cent., from the Tennessee and Kentucky district 5 per cent. and from the district including Iowa, Texas and the Southwest States, 4.8 per cent. Material decreases in shipments were as follows: Western Pennsylvania, 6 per cent.; Ohio, 3.6 per cent.; the district including northern Kentucky, high volatile of southwest Virginia and Virginia anthracite fields, 7.8 per cent.; southwest Virginia, 16.8 per cent.; Alabama, 17 per cent. and the district including Illinois, Indiana and western Kentucky, 6.1 per cent.

Anthracite shipments during the week ended Aug. 3 decreased 1310 carloads or 3.2 per cent., the total movement amounting to 39,632 carloads.

Beehive Coke—Production of beehive coke in the United States during the week ended Aug. 3 is estimated at 606,000 net tons, a slight decrease compared with the week preceding. The average daily production during the current week is estimated at 101,000 net tons as against 103,000 net tons during the week of July 27. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke, during the week ended Aug. 3, at 342,644 net tons and operation of the plants at 76.5 per cent. of their present capacity as against 76.6 per cent. during the week preceding. The carriers furnished a 100 per cent. car supply during the week. The same operators produced 164,350 net tons of coal.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: July 13	July 20	July 27	Aug. 3
Bituminous shipments, 123 roads	235,291	229,770*	228,331*	220,823†
Anthracite shipments, 9 roads	42,419	40,664	40,942	39 632

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

Dry Goods Economist—Cotton and cotton fabrics received the major share of attention in all discussions of conditions in the world of dry goods this week. The two conflicting estimates of the condition of this year's cotton crop had just one point of unity. Each indicated a surplus, and of the two surpluses even the smaller one was large enough to cause men in cotton goods salesrooms to shrug their shoulders when asked what would become of prices if the holders of the surplus cotton decided to realize on it.

Bradstreet's—Trade and industry are quieter this week. Extremely hot weather has acted as a deterrent to industry, and though war essential lines are crowded with orders, civilian business in many lines tends to reflect more conservatism. This relative reaction proceeds from high temperatures, which have discouraged indoor and outdoor work, besides buying at retail, from the continuous induction of men into military life, which is telling on purchases of civilian attire, and from the fact that corn and cotton crop news is decidedly less favorable. The hot wave has, of course, cut down production of manufactured articles, and reorders are light, while less essential industries are being crimped more and more, either by governmental action or by the indisposition of the banks to advance large credits to the so-called non-essential lines.

American Wool and Cotton Reporter—The South American wool situation has been uppermost in the minds of the wool trade, particularly as to the question of getting wools into this country which have been previously bought and stored in South America. Some of the trade are protesting against the fact that not all established houses have been permitted to share in the purchase of this wool. The new clip is coming in fast from the West. The cotton market has taken a decided change. Many have become convinced that there would be a large crop of cotton and that without Government price fixing the weight of cotton would be such that prices would be depressed radically. Cotton is in a strong position and even though the carry-over will be great, the price is not likely to be specially low, and possibly not much lower that it is at present.

Atlantic Seaboard

BOSTON

While situation is comfortable as to current supply the undertone is one of apprehension. Apparently a fixed idea in Washington that New England requirements have been set too high and only through vigorous action will coal be allowed to come forward more than a few weeks longer on the present basis. All-rail movement from Central Pennsylvania continues favorable Wagon coal is a distinct help, although care has to be used in distribution. Shortage of labor makes unloading difficult. Similarly there is more congestion of steamers due to the lack of berth room to discharge railroad fuel. Hampton Roads dispatch is good, but the volume of coal running to the piers has already been reduced, and trouble is ahead when bottoms again reach the loading ports. Baltimore loading continues fair, although the diversion of coal from New York piers still presents a problem. Effort to make up anthracite arrears by shipments all-rail.

Bituminous—While the situation is still curiously mixed and some plants are overwell stocked and others have practically no reserve, the market is what in ordinary times would be called "easy." No consumer finds it difficult to get steam grades, particularly if he is willing to pay the price for water-borne coal. Largely for this reason, many of the small buyers have been lulled into a sense of security, as if coal were always coming forward on the present basis. In other words, all the circumstances would have to continue just as they are now, with an increased tonnage either for lake or other territory or for bunker and other Government requirements, and even then it would be extremely difficult for New England to pile up the reserves really necessary for continued operating during the winter. The larger railroads still have less than 40 per cent. of the reserve it has

always considered only prudent for them to have on hand by Nov. 1, and certainly curtailment now would be nothing short of disastrous in its effect upon New England in December and January.

Those having supervision at Washington are of course beset by serious problems. The heavy movement of troops and enlarged Government activities abroad, not to speak of additional ships for the naval force overseas and the demands of our Allies, all mean increased use of coal, and with all the advertising that has attended New England's efforts to get coal it is only natural the authorities should look to this territory as likely ground for curtailment. It is argued that from Apr. 1 to July 1, there was on paper a shortage of 2,000,000 tons, and yet all the wheels have kept turning. This, however, takes no account of the great extent to which coal has always been accumulated in New England against cold weather when deliveries both by rail and water slow up. One has only to compare receipts today with the volume of coal coming in last January to realize how much New England is dependent upon a reserve supply. Unconsciously those more familiar with conditions in the Middle States, where customarily reserves are much lighter, are apt to measure New England by their own yardstick.

All-rail movement from the Central Pennsylvania district has thus far been maintained on the July average, about 690 cars bituminous, including railroad fuel. The volume of shipments is therefore quite favorable, but it will probably not be long before there are whisperings of car shortage. This always reacts first against New England, although it will be interesting this year to observe the result in this respect of Government operation and the pooling of cars. Just now the situation is of some difficulty because we have good receipts by water; at the same time volume shipments by rail are reaching many of the mills, and in such way as to cause slow unloading. One result is a report through the Railroad Administration that New England is holding up cars and nothing could be more serious as bearing upon efforts here to keep coal coming continuously on the present basis. Here as elsewhere the labor shortage makes prompt rehandling next to impossible. This is especially apparent on wagon coal in box cars which is now being sent to New England from off the Pennsylvania railroad. Great care has to be exercised in distributing this coal to avoid just the kind of car congestion already referred to. The volume of this coal amounts now to perhaps 15,000 tons per week, and is a distinct help toward building up the desired reserve, particularly among smaller consumers and retail dealers.

Early in July there was so much anxiety over railroad fuel, and pressure was brought on Washington to such extent, that a large number of steamers were arranged for to freight the coal. One result is that for a fortnight past there has been actual congestion at the Boston piers and in several cases cargoes intended for railroad supply had to be unloaded for other purposes. In other words, there was a lack of berth room for the number of ships coming forward to the railroad wharves. Arrangements were made this week to work 24 hours a day, and the situation in this respect has materially improved. Apparently ships were loaded for Boston both at Hampton Roads and at Baltimore without much regard to the berths where they would discharge, and it has taken a good deal of ingenuity to give these ships anything like good dispatch. It has been expensive for the railroads concerned, but a suitable reserve is so necessary that no complaint is made.

Temporarily the volume of coal available at Hampton Roads is about on a level with the tonnage reporting, but already there are signs that the amount of coal running to the piers will soon be reduced. By-product plants and the Western trade will now come in for their share, and detention will certainly follow for coastwise ships. Coal is running to the Baltimore piers in fair volume and thus far the dispatch has been good. A proportion of the coal, however, has been taken from the Western and line trade, and it is likely the volume of coal there will also be materially reduced. As it is now quite a tonnage is being diverted to Baltimore from coal that ordinarily runs to the New York piers for Long Island Sound points. How this tonnage is to be made up to ports like New Haven, Bridgeport and New London is still a problem. Most seriously does this affect illuminating gas plants that have relied upon regular receipts from the Fairmont region.

Anthracite — Domestic sizes all-rail are still being received in good volume. Movement through the five gateways continues on a 600 car per day basis. Retail dealers at many of the inland points have had more tonnage than last year at this time, but so great is the demand from the consumer that there is no accumulation anywhere. Deliveries by team are made as fast as receipts by car will permit.

The same thing is true of tidewater dealers, now that an increased effort is being made to build up the receipts of the latter by increased deliveries all-rail. This is being done all along the coast and the number of cargoes actually shipped does not measure the tonnage sent forward.

There continue to be many problems of distribution before the anthracite committee, and only gradually are these complications being cleared up. In many ways 1916 distribution presents an awkward basis for shipments this year, since in the fall of 1916 shipments were notably irregular.

NEW YORK

Anthracite moving easier and dealers optimistic. Excessive heat causes falling off in dumpings. Buckwheat No. 1 in good demand. Bituminous situation shows slight improvement. Demand continues and spot buyers make slow progress. Cars reported better.

Anthracite—Coal is moving easier and the entire situation is an improvement over the previous. While the dumpings for the week ended Aug. 9 show a decrease as compared with the previous seven days, the local trade seems to have handled more supplies. Locally the dealers complain of a lack of egg and stove, with broken, chestnut and pea much easier.

The market is in a fair way now to obtain supplies commensurate with its increased requirements and there are those who believe that orders similar to those issued by the anthracite committee of the fuel administration with regard to shipments to New England, will be sent out with respect to this market. Conditions with regard to the fuel supply in towns on Long Island are said to be bad, and the same is true of near-by towns along the water front which get their coal from this tidewater.

Receipts here are being drawn heavily upon because of orders issued by the anthracite committee of the fuel administration to producers and distributors stating that during this month water shipments to New England should be up to the maximum available boat equipment. At the same time all-rail shipments are to go forward on the present year's basis of allotment to each state. The committee also ordered that shipments of domestic sizes, including pea coal, shall be discontinued to 44 communities in Massachusetts, 45 in Connecticut and 146 in New Hampshire, directing that shipments shall be concentrated to other points in these respective states.

The improvement in the situation has not interfered with the activities for conserving fuel. A movement is on foot looking toward a union of church services in Brooklyn for the winter. Household consumers are securing their requirements in good shape and with reasonable receipts the situation is likely to be satisfactory by early cold weather.

Conditions in the mining fields are good. Production is heavy and with the labor situation remaining as it now is, operators believe they will be able to avert a coal scarcity such as the country faced last winter. It is estimated that of the 26,000,000 tons of anthracite mined during the first four months of the present coal year, 17,500,000 tons of domestic sizes have been placed in consumers' bins. A movement is also on foot to have the mine workers observe Labor Day by remaining at work, but this will not probably be accomplished. With all the mines idle it is estimated there will be a loss of 275,000 tons in production.

There was a loss of 605 cars in the dumpings at the local tidewater docks for the past week, 7004 cars having been dumped as compared with 7609 cars the week previous. Much of this loss was due to the excessive heat, the men at some of the docks refusing to work one entire day.

The steam coals continue active with the heavy demand for Buckwheat No. 1 continuing. Rice and barley are somewhat easier, but by no means plentiful, and with quotations at full circular prices.

Current quotations, per gross tons f.o.b., tidewater, at the lower ports, are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Pea	$5.20	$5.95
Egg	6.35	7.10	Buck	5.10	5.90
Stove	6.60	7.35	Rice	4.65	5.10
Chestnut	6.70	7.45	Barley	4.15	4.30
			Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—Conditions are slowly improving. While free coals continue to be out of the market, regular customers are receiving good-sized supplies and the situation is in better shape. However, larger receipts would be welcome. Cars at the mines arrive in larger number, and some operators say they would be unable to load many more with the present labor supply.

The demand is steadily increasing, war industries asking for more coal than has yet been allotted to them. There has also been a heavy increase in the requirements for bunker fuel and producers whose mines were classified in either Pool No. 1 or Pool No. 71 are finding a ready market for their output.

Orders have been issued discontinuing Pool No. 72 as overseas bunker fuel. This pool was formed a few weeks ago by taking certain coals from Pool No. 10. These coals now revert to Pool No. 10, leaving Pools Nos. 1 and 71 as the exclusive pools for overseas bunker fuel.

Dumpings at the local tidewater docks for the week ended Aug. 9 show that 6763 cars were dumped as compared with 6619 cars the week previous, an increase of 154 cars.

Producers say conditions at the mines are gradually improving. Labor is more settled and, with cars moving easier, production is steadily showing an increase. Shipments to the New York market from central Pennsylvania for the week ended July 20 were 3534 cars as against 3325 cars the week previous.

There is a decided effort being made here to conserve fuel. Outside of the observance of "lightless" nights, one of the department stores is now open from 10 a.m. to 4:30 p.m. five days a week. Saving of fuel is also being accomplished in most of the big office buildings.

Stocks at the various docks are low. Spot buyers report few purchases and these far between. Bunkering is steady with the result that there is little surplus on hand.

Current quotations, based on Government prices at the mines, net ton f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite activity halted temporarily by heat. Overshipments to some sections cause trouble. One company close to quota on local trade. Outlook seems better. Labor question unsettled. Public works getting good supplies. Stove and nut in heaviest demand. Steam situation unchanged. Good tide business. Bituminous car supply improved. Good shipments received. Plans for increased production.

Anthracite—Due to the unprecedented hot weather, the various sales agents report the trade has allowed them a week of comparative quiet. They have had fewer personal calls from the dealers than for many weeks and even their telephones have been quieter. The heat also interfered to a considerable extent with retail deliveries and many yards shut down completely during several afternoons. The demand also fell off, temporarily, but will increase now that September is near with new prices going into effect in the fall.

The feature of the week has been the unusual shipments to West Philadelphia, and the methjod of shipping has been severely criticized. Several dealers received more coal in a few days than they could possibly unload in so many weeks. The dealers were anxious for the coal, but in some cases there was considerable transferring. The new car service rates make the rates so exorbitant for demurrage that it is out of the question to allow the cars to stand any length of time. Later when these same dealers ask for more coal they fear the fuel authorities will take the stand that they have not coöperated with them.

It would appear to some that the authorities have judged by the unfilled orders and where a dealer was a few thousand tons behind on his deliveries, took it for granted he would be glad to receive the coal at once. There are others who intimate the shippers complied with these requests of the local fuel people and shipped as they directed, only to show them that they had not yet mastered the situation.

In directions other than West Philadelphia the shipments have not been free and at least one big company is advising its trade that it expects to be one month behind until the New England situation has been relieved. This company has large obligations in New England and the in-

creased percentage ordered there was the cause of restricted shipments to customers in this city.

The company above referred to was also ordered to supply a large block of coal for the public schools here. This is business it has not handled before and further upset their plans for their local trade.

At the office of another big company it was learned that its most desirable trade had received its quota for the first quarter of the 1916-17 coal year, and in some cases this included the increase of 18 per cent. The fuel administration has cut off so many places to which this firm formerly consigned coal that its responsibilities have been greatly relieved. A spirit of optimism is manifest that has been absorbed by some of its largest buyers. Several of the largest retailers state that while they expect trouble all winter they are satisfied the experiences of last season will not be repeated.

Broken is now never heard of as a domestic fuel. Consumers of this size have been converted to the use of egg. Egg coal is not short, except in the suburbs. Stove and chestnut continue to be the sizes most sought after by the dealers and unfilled orders call chiefly for these two sizes. Pea is now actually easy with some dealers but by winter will undoubtedly be in greater demand than any of the other family coals. Less pea than either egg, stove or nut has been ordered and consequently by cold weather there will be less stored in the cellars. Naturally the dealers are crying for it, for they know of the coming demand, but there are a number who even now have fair stocks.

There has been no noticeable change in the steam trade recently. One week is simply a repetition of the preceding one. As a matter of fact there is little solicitation now on the part of steam users for further supplies, as they have by this time felt out all the possible sources of increased supplies. Old customers continue to accumulate almost unusual stocks of all the steam sizes. This is especially the case with several large department stores, who are accumulating extra large stocks on vacant lots. There is little culm activity locally, but heavy shipments are still going forward to eastern points. There has also been an increase in the tide shipments, but the rail movement to eastern points is still considerably in excess of normal.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—This week there has been a considerable improvement in the car supply, although there has been no change in the situation as to the adoption of the old rating plan by the Pennsylvania R. R. in the central Pennsylvania region. As a consequence of the improved car supply shipments received here have also increased and essential plants are adding to the already quite large stocks they are accumulating.

Plans are well developed by local operators whereby a systematic effort is to be made to encourage the miners to increase production. This is in pursuance of the Government's plan to have a committee of miners at each operation take charge of this problem and thus reach the men and keep them constantly impressed with the importance of their work to the nation.

BALTIMORE

More than 100 cars of special relief coal aids situation here. Conditions remain tight, however. Complaints of quality heard, even on preferential coal. Little change in anthracite situation except that deficit on apportionment grows.

Bituminous—Faced with facts to show that many important industries not on the actual preferential list were in dangerous condition as to fuel supply, the Washington fuel administration officials arranged for diversion of more than one hundred cars of soft coal to Fuel Administrator Meyer the past week. These came in small batches from District Representative Brydon and in considerable measure were assigned to the packing business which had been hard hit for lack of fuel at the height of the packing season. Others went to the more urgent needs on a list held by the fuel administrator, and by a close distribution and the aid of local coal men the situation was tided over and is still being handled in that fashion.

There is at present wide complaint as to the grade of coal coming through. For a time such complaints were made by those outside of preferential delivery, and the granting of best coal to war industries and public service corporations was given as the reason for the poorer grades reaching general business. Now there are also complaints from every source of much dirty coal. Numerous rejections have been noted from the Tidewater Pool, and a curtailment of street car service in this city the past week was blamed by the electric line officials largely on poor grade coal that cut down boiler efficiency.

Anthracite—Not much change is to be noted in the hard coal trade here. Receipts continue below normal. The local fuel committee has been promised that the full allotment will finally come through—just when is a question. Whether enough can now be secured to give all consumers here the planned two-thirds on orders before winter sets in is extremely doubtful. Some coal men are frank to say that even if the coal was poured in in unexpected quantities in September that the war-limited equipment and forces of the dealers here would not allow of its handling.

Lake Markets

PITTSBURGH

Production well maintained. Ample Lake transportation facilities. Coal needs of the iron and steel industry. Practically no market.

Production of coal in the Pittsburgh district is well maintained and with long range comparisons shows a material increase. There is no surplus of rail coal for stocking purposes, however, as the rule still holds good that after the current requirements of essential industries are taken care of the balance must be shipped in the Lake trade, and the Lake shipments thus far have not increased greatly over the allotments made prior to the ruling that the Pittsburgh district would have to make up for the decreased shipments from West Virginia and Kentucky due to their being required to furnish much more coal for the Navy.

There is an ample supply of Lake transportation. The Lake fleet moved in July 10,659,203 tons of iron ore, making a new record for a month, while the railroads are handling the coal to Lake ports well, no congestion at docks being reported.

If the steel mills require anything like the amount of coal the War Industries Board estimates the Pittsburgh district and other regions serving the steel industry are going to be kept very busy, for in a recent conference the War Industries Board informed the Fuel Administrator that the steel requirements for the present half year are 22,000,000 net tons, and that nearly five tons of coal is required per ton of steel, so that 110,000,000 tons would be needed for the half year. The demand was evidently made with a view to its being scaled down, for coal is hardly plentiful enough to give the iron and steel industry a supply equal to 220,000,000 tons a year. The board had previously undertaken to remind the steel industry that it had never made more than 16,500,000 tons in a half year, and it is obvious that more coal is not the only requisite in increasing the steel output. The allowance of five tons of coal per net ton of finished steel is also excessive. A fair estimate, though a rough one, would be 70,000,000 net tons of coal a year to produce the coke the blast furnaces use, and about 80,000,000 tons a year, for power, for producer gas and for heating steel, making 150,000,000 net tons of coal a year, or 75,000,000 tons for a half year. This amount would probably represent the outside consumption possible by the iron and steel industry if everything else were absolutely favorable to its full operation.

The condition remains that there is practically no open market in coal, such transactions as occur being in almost all cases the result of allocations. The brokers are doing but little business now. The market remains quotable at the set maximum prices: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c extra permitted to be charged by brokers to buyers.

BUFFALO

Trade slowing up somewhat. Diversion of coal to other points probably the reason. Cars more plentiful. Fear entertained that this district will run short.

Bituminous—The market is hardly keeping up with former activity and there is some uneasiness on that account. The question is how long the diversion of coal that is naturally tributary here will go on. If it lasts all the summer and fall it will leave this territory short of essential requirements. Coal that would otherwise go to points in this territory is being ordered to New England and up the Lakes, so that the operators themselves do not know what promises to make or what orders to take.

At the same time all jobbers and sellers are trying to be active. Some of them are sending out extra men to hunt for coal in order to keep a supply for their customers. They have about dropped the practice of selling at delivered prices. So many items must be added, such as freight, war tax, profit and the like that mine prices have been adopted to a great extent. Everything is so subject to change that often a shipper is unable to fix a delivered price and be safe in it.

This state of things, so many dealers with prices of their own, is such that it often takes considerable figuring and estimating to give a quotation. Consumers appear to understand this and are not insistent on this or that price. What they want is coal. They can no longer buy what they need in the open market. If they get coal for their manufacturing they are pretty sure of a good profit, no matter what it costs. If they do not get it they can do nothing.

Allowing for minor differences the prices of bituminous are $4.65 for thin-vein Allegheny Valley coal, $4.45 for Pittsburgh lump, $4.20 for mine run and slack, $5.85 for smithing and smokeless and $5.50 to $6.10 for cannel, all f.o.b. Buffalo per net ton.

Anthracite—The demand is as insistent as ever, in spite of hot weather. Advices from Canada agree that the amount possible to be got into that territory is sure to be light, but wood and bituminous coal will be laid in to take its place. Shippers and retailers do not agree as to the amount put into cellars here. One says the ordinary amount is delivered and the other is sure of a shortage.

CLEVELAND

Signs are becoming increasingly evident that the movement of bituminous coal to the Northwest must be continued until near the end of navigation. Shipments, which at the end of July were a round million tons behind the Fuel Administration's schedule, continue losing at the rate of 200,000 tons a week. Official orders have been received by operators in the Pittsburgh vein district of southern Ohio, that they are expected from now on to turn over 1200 cars daily to the lake trade. Industrial stocking of bituminous may well be said to be at an end, for the present.

Bituminous—Famine conditions seem inevitable until the close of navigation on the Great Lakes now that D. F. Hurd, secretary of the Pittsburgh Vein Operators' Association of Ohio, with offices in Cleveland, and zone director for the Fuel Administration, has formerly notified operators in the Pittsburgh vein district of southern Ohio that they are expected to provide the lake trade at least 1200 cars a day from now on. This means that receipts for industrial and domestic purposes here will be cut fully 50 per cent., and receipts for the past three or four weeks have been far short of spot requirements. The latest report of the output of operators who belong to the association, which covers the period ended July 21-31, shows that the output totaled 9005 cars, of which 1886 cars went for railroad fuel, 4778 to the lake trade, 1772 to Ohio, 450 to Indiana and Michigan and 119 to Canada.

Shipments of No. 8 coal from members of the association in July as compared with July, 1917, according to official figures compiled by the association, were:

	July, 1918		July, 1917	
	Cars	Per Cent.	Cars	Per Cent.
Railroad	6,094	23.01	7,336	37.91
Lake	12,980	49.37	6,428	33.21
Trade	7,262	27.62	5,590	28.88
Totals	26,291	100.00	19,354	100.00

From this it will be seen that to divert 7200 cars a week to the lake trade will require more coal than was produced for all purposes in July.

Labor conditions in the southern Ohio coal regions are reported only fair, with no prospects of immediate betterment by reason of the increased demand of the war services for men. Car supplies continue at between 90 and 100 per cent.—in any event ample for the labor forces. Detailed figures on the car supply accorded members of the Pittsburgh Vein Operators' Association of Ohio for July are:

Railroad	Car Rating	Supplied in July	Short	Tons Short
B. & O.	16,509	13,794	2,715	135,750
Penna.	9,166	8,174	992	49,600
W. & L. E.	8,263	7,306	957	47,850
N. Y. C.	2,236	1,958	278	13,900
Total	36,174	31,232	4,942	247,100

Anthracite—Due to the operation of the zoning system virtually no anthracite or smokeless coal is entering this market.

Lake Trade—Bituminous is coming forward liberally to lower lake ports, and cargo space is ample; but shipments seem not to be able to get much ahead of 1,000,000 to 1,050,000 tons a week. With a schedule calling for 4,900,000 tons each in August and September, and the lake movement a round million tons behind by the close of July, it can readily be seen why lake vesselmen see the coal season continuing up to the very end of navigation. Revised figures for the week ended Aug. 3 place the shipments at 1,050,000 tons. The estimate for the movement in the week ended Aug. 10 is the same. Reports that Pittsburgh vein operators in southern Ohio would be called upon to supply 1200 cars daily for the lake trade have become fact with the issuance of such an order in the past week. This is one of the results of the visit here ten days ago of Charles P. White, who is in charge of lake and Canadian coal shipments for the Federal Fuel Administration. Government figures show that in July 2,121,603 tons of bituminous coal passed upbound through the Soo canals, while anthracite shipments amounted to 233,764 tons.

DETROIT

Inadequate supply of anthracite and domestic bituminous alarms Detroit manufacturers, who fear migration of labor. Lake movement holds volume.

Bituminous—Distribution of winter fuel in Detroit is still impeded by the restricted supply of domestic stock available. Jobbers report fair amount of steam coal is coming into the market, though the quantity is not sufficiently large to provide a reasonable supply for building reserves after provision is made for the day to day needs of steam coal users. The stock reaching the city is largely mine run of a character unsuitable for use in household heating plants. The proportion of lump and domestic coal is small and jobbers say little success attends their efforts to increase the supply.

Users of steam coal are actively in the market. There is no free coal on tracks and the accumulation of reserve supplies is not general, though some of the larger establishments have succeeded in putting aside a comfortable surplus.

Anthracite—Detroit's anthracite receipts show no improvement. Instead of shipments arriving in increased volume, as the season advances, it is reported the movement has dwindled down to around 18 or 20 cars a day. With the great r proportion of Detroit's domestic consumers having heating plants in which anthracite is ordinarily burned, the situation is assuming an alarming aspect. Manufacturers assert that continuation of operations on war orders is likely to be jeopardized by an exodus of labor from Detroit unless immediate action is taken to increase the present supply of coal and improve the prospects for augmenting the supply later.

Representatives of several large corporations have been appointed to a committee which will go to Washington within a few days to present an appeal to the war industries board, the shipping board and the secretary of war. The committee will also appeal to the federal fuel administrator, if he is back from his vacation. In the effort to improve Detroit's situation, the local Board of Commerce has appointed Edward J. DuBois, vice-president of the American Coal and Coke Co., as a permanent representative in Washington.

Lake Trade—Shipments of coal over the Lake routes are showing a slight increase in volume, and for the week ending Aug. 3 carriers loaded 1,050,000 tons. This is the heaviest movement of any one week for the season. Even this falls short, however, of the schedule of 4,900,000 tons which shippers had decided would be necessary for the months of August and September to assure supplying the Northwest before the coming of winter.

COLUMBUS

The hot weather has had its effect on mining operations and production is smaller. Lake trade is booming. There is a good steam and domestic demand.

The extreme hot weather which has prevailed for a week has had a bad effect on mining operations. Miners are not as active; neither are tipple men or outside labor. The result is that a curtailment of production, while not marked, is having its effect on the demand. Retail trade is active and there is not a great deal of coal going to the dealers because of priority orders. On the whole the tone of the trade is good and prospects are considered bright.

Lake trade is now attracting the major part of the attention of producers and shippers. Under orders from W. D. McKinney, federal representative, about 85 per cent. of the production of Ohio mines is being moved to the Lakes for shipment to the Northwest. Reports show that there is still a shortage in the upper lake region although this is not as bad as earlier in the season. The vessel movement has been good.

The domestic trade is rather quiet, although there are frequent demands for tonnage on the part of dealers. Consumers are placing orders rapidly as a survey of the state shows that many householders have not yet arranged for the winter's fuel. Retail prices are firm at the levels which have prevailed for some time. Retail stocks are small. Some West Virginia splints are on hand but the amount of Pocahontas is small.

Steam demand is also strong but a minimum tonnage is allowed steam users. The question of necessity enters largely into apportioning tonnage for steam plants. The smaller users as well as the heavy consumers have been able to accumulate a fairly good surplus and as a result industry is not suffering. Many large consumers have enlarged their storage facilities and have a larger tonnage on hand than ever before.

Production is rather good despite the labor shortage and the extreme hot weather. The Hocking Valley is working at about 85 per cent. of capacity and eastern Ohio is producing in the neighborhood of 80 per cent. Other fields also show good production figures.

LOUISVILLE

Production continues comparatively light, with car supply inadequate, and labor somewhat harder to secure. Steam demand is normal, with domestic demand heavy, and dealers well behind on orders. So far dealers have been unable to secure any surplus.

Deliveries of coal to steam and domestic consumers have been handicapped somewhat during the past week by the hottest weather in 17 years, the thermometer going to 105 deg., on Monday, Aug. 5, with a street temperature of 117 deg. This made it hard to hold men, and keep animal-drawn carts moving. This has been the most peculiar season of many years. Just after the first of the year the coldest weather for 40 odd years was experienced, and now we have the hottest weather since 1901.

Production in the eastern Kentucky fields is showing no improvement, and is dropping off in the western Kentucky fields due to the heavy drafting of negroes, who are claiming few exemptions, and patriotically reporting when called. With the starting of the cotton picking season it is expected that many negroes will leave the mines for a time, making the situation still worse.

Heavy movement of coal into the Lake district has made the car shortage more acute. However, the use of coal cars is being materially restricted for handling coal alone, and this should aid things somewhat.

In Indiana and points west of the Mississippi florists are having an easier time of it than in the Eastern sections. Indiana florists have been advised that they may burn low grade Indiana screenings in addition to their 50 per cent allowance of steam coal. Efforts of Kentucky florists to secure the same advantage have been of no avail.

BIRMINGHAM

No important changes in market conditions. Demand strong for all grades. Supply slightly improved. Production last week reached highest recorded figure. Shortage of cars causing loss in output at some operations.

The past week did not develop any material change in trade conditions locally. The production for the week ending July 27 showed a gain of about 15,000 net tons over the output of the previous week, according to figures compiled by District Representative E. A. Homes, of the Fuel Administration. This was a record production for Alabama, and it is expected that a substantial increase will be noted each week from now on.

Inquiries for steam coal are showing no diminution and the requirements are in excess of the supply available. The slightly increased production has not affected market conditions as yet, and the output will not likely reach such proportions as will greatly ease the tenseness of the demand on this district.

Domestic trade continues steady and records indicate that more domestic coal was bought by consumers in July than the preceding month. Dealers are delivering coal from the cars set into their yards in many instances and only a few retailers have any coal in stock.

Men in the coal-mining district as a whole appear to be working more steadily, though there is yet much idleness among the mine workers, which is causing a heavy loss in the output. Mines on the Frisco have lost some time during the past week, from one hour to a whole day, waiting on equipment for loading, coal cars being rather short with this line.

Coke

CONNELLSVILLE

Continued completion of by-product ovens. Connellsville ships more raw coal. Ruling on cleaned coke. Merchant oven output maintained.

The feature of the coke situation continues to be increased production of by-product coke. At the Clairton plant of the Carnegie Steel Co., where the first coke was made late in June, the first battery of 128 ovens is now in full operation and producing about 10,000 tons of coke per week. This is sufficient to operate the three Clairton blast furnaces. The second unit is expected to be in moderately full operation by the fore part of September, and three more units by the end of the year. Completion of the remaining six units will occur much later.

The Lorain plant of the National Tube Co., which will embrace 208 ovens altogether, now has half its ovens in practically full operation, with expectations that the remaining half will be in practically full operation within 60 days. The 180 ovens at Cleveland of the American Steel and Wire Co., where the first coke was made in May, are now in full operation. A few of the 204 additional ovens of the Youngstown Sheet and Tube Co. were completed a few days ago, but are only now starting, as there was a delay in receipt of additional coal supplies.

These various new plants draw their coal largely or wholly from the Connellsville region, which accordingly has much difficulty in maintaining its coke production in face of the additional coal that must be shipped. The last week reported upon showed merchant ovens operating at as good a rate as they have attained this year, but production by furnace ovens decreased 12,000 tons. This is the only decrease attributable to the drain of new by-product ovens, so that on the whole the production of coke, by one process or another, from Connellsville coal is increasing.

The local fuel administrator has ruled that coke that is screened and otherwise cleaned may be sold at as high as $6 if it is not in prepared size, and it would appear that even if it is screened from an old dump it would be permissible to sell it at up to $7.30 if over ¾-in. Such material, from old dumps, has brought up to $6.50 and while it is practically as good for heating purposes as new crushed coke its appearance is against it and the retail dealer must be given a concession in consequence.

Scarcely any furnace coke is offered in the market, but a number of operators continue to offer foundry coke rather freely and the foundries appear to be stocking up. The market remains quotable at the set limits, as follows: Furnace, $6; foundry, 72-hr. selected, $7; crushed, over ¾-in., $7.30, per net ton at ovens. Screened and cleaned coke not sized is limited to $6, cleaned crushed under ¾-in. to $5 and breeze to $3, but these prices could hardly be obtained.

The Courier reports production in the Connellsville and Lower Connellsville region in the week ended Aug. 3 at 340,980 tons, a decrease of 11,645 tons. The decrease was wholly in the furnace oven production, the merchant oven production increasing 550 tons to 142,930 tons.

Buffalo—The demand is heavy, as all furnaces are running strong. It is always hard to get a supply, but, at least, this is accomplished to such an amount that no shutting down is reported. Jobbers do not try to handle coke but get a good profit on the breeze that they obtain from the by-product plants.

Middle Western

GENERAL REVIEW

Operators disturbed over Fuel Administration's rulings relative to sized screenings and modified mine-run. Shortage of skilled labor. Idleness reported on account of poor car supply.

Coal operators in the Middle West, in general, and in the southern part of Illinois,

in particular, are disturbed, to put it mildly, over the recent decisions of the Fuel Administration relative to sized screenings and modified mine-run.

The Fuel Administration's statement No. 667 reads as follows: "For all special sizes passed over a mesh over ½ in. in size the mine price for prepared coal is allowed." This paragraph clears up a doubtful point; namely that such coal from Franklin County or Williamson County as special stove (2 x 1¼ in.) or domestic chestnut (1¼ x ¾ in.) shall be considered as much a prepared size as lump or egg. The ruling goes on to state, however, that for special sizes passing over ¼-in. and under ½-in. screens, the mine price for run-of-mine coal is allowed. This classes as mine-run carefully prepared pea coal (½ x ¼ in.), which is given just as much care in producing and preparing as the larger sizes. This coal is not used at all extensively for domestic purposes, except perhaps for underfeed furnaces, but makes a highly efficient steam fuel. This pea coal, or No. 4 nut, as it is sometimes called, is just as expensive to produce and prepare for market as the larger prepared sizes, and there is a question in the minds of the operators affected just why the Fuel Administration made this differential. The ruling goes on to state as follows: "For all fine sizes passing through a mesh of ½ in. or smaller the price fixed is 30c. per net ton less than the prevailing price for standard screenings. If fine screenings or carbon, passing through ½-in. or smaller mesh as a result of producing specially sized screenings are mixed with other coal, the selling price shall not exceed the applicable Government price, less 30c. per net ton." This reduces the price on carbon, or No. 5, as well as ¾-in. screenings from $2.05 per ton to $1.75 per ton. Roughly speaking, 20 per cent. of the entire output of a southern Illinois mine is ¾ or ½-in. screenings. This reduction of 30c. per ton is a serious matter to these operators.

Another ruling unfortunate for the Illinois and Indiana operator was issued around the first of the month. This ruling modifies to a large extent the United States Fuel Administration's statement No. 617, issued July 6, which allows for special prices on modified mine-run. According to the original statement, No. 617, modified mine-run is mine-run passing through a screen with 2-in. perforations up to 6-in. perforations. The new ruling states as follows:

"In certain districts there are mines which prior to Jan. 1, 1916, used 2 to 2½-in. standard screens and which consequently should sell coal passing through such screens at the applicable slack price, according to the terms of the order of May 27. These same mines are now reported as billing this product at the modified mine-run price, thereby overcharging the consumer from 10 to 12c. a ton."

In other words, if an operator in Illinois made 2-in. screenings prior to January, 1916, he can only charge $2.05 per ton for such screenings. If, however, he made 1¼-in. screenings at that date, and say six months ago changed his screens to 2 in. then he is entitled to charge for his coal on a modified mine-run basis, which would bring 2-in. screenings up to $2.17.

The labor situation in the field is practically unchanged. There is a tremendous shortage of skilled labor, such as machine runners, and motormen, but there is a plentiful supply of common labor. The local exemption boards are reported to be coöperating with the operators and helping them in every way to procure men for the mines. The car situation for this period is not as good as it has been for the past few weeks.

CHICAGO

Heavy production almost resulted in sharp break in market. High grade coal scarce. Lower grades selling freely. Car supply poor.

There is not much change in the Chicago market. High grade coal is still difficult to purchase, and the medium to lower grade products are selling freely on a basis of "Government price current at time of shipment," or below this basis.

The recent heavy production periods nearly brought about a sharp break in the market, but this was avoided by placing a large tonnage in the lower peninsula of Michigan, as well as parts of Ohio, for Indiana coal. In addition, the car supply has not been as good as it had been for the past few weeks, and this was also a factor in keeping the market fairly firm.

MILWAUKEE

Fuel administrator receiving complaints of overcharge on the part of some dealers. Registration of coal and coke distributors.

The coal market, if the present method of trading in coal can be called marketing, is abnormally active for the season. Small dealers complain that they are not allowed sufficient hard coal to keep their teams busy. Some say that at the present rate of supply they will not be able to fill their orders until next spring. Bituminous coal, however, is being handled freely.

An additional charge of 75c. is being made by some hard coal dealers on what they term "premium coal," or coal secured by them after special effort and at above normal expense. This has resulted in complaints of overcharge. Fuel Administrator Fitzgerald has referred the matter to headquarters at Washington for instructions. Meanwhile the dealers interested will continue to exact the extra sum.

The anthracite coal situation is improving, as far as this district is concerned, and the opinion is expressed that there is now hard coal enough in sight to meet the needs of the state on the basis of current restrictions. The recent advances of 40c per ton was made, it is alleged, to cover increased freight rates. The new retail margin decided upon by the advisory board of the fuel administration has not yet been announced, but it is practically the same as the margin now in force—$2.25.

The work of registering coal and coke dealers in this district is now in progress. Every fuel handler, including organizations distributing coal to employees or members, must register by Aug. 20, with county fuel administrators, and the certificate of registration must be posted conspicuously. Coal and coke wholesalers are warned, under severe penalty, not to sell or ship fuel to those who have not complied with the registration order.

Two cargoes of hard coal, aggregating 15,300 tons, were received since last week's report. A feature of the week was the docking of a record-breaking cargo of bituminous coal—13,768 tons. August will be a big month if the present volume of receipts is kept up. The record up to and including the 7th, is 15,300 tons of anthracite and 163,716 tons of soft coal.

ST. LOUIS

A continued quiet market, with a let-up in the domestic demand on everything except Carterville. Steam sizes moving slow. Hot weather affecting shipments. Car supply poor, while movement shows improvement.

In St. Louis proper the coal situation is almost at a standstill. The weather the past week has been the warmest on record here for 17 years, and it has affected domestic deliveries. Many of the inexperienced drivers who take the places of those who have been drafted quit after making a load each day, and many of the larger companies had two-thirds of their equipment in the stable. The result is that the yards are pretty well loaded with coal, drawing demurrage, and the scarcity of help to unload steam coal has caused a surplus of steam sizes to accumulate.

In the Southern Illinois field there has been a scarcity of water at many of the mines that is interfering with production. Car supply has been poor in the Carterville field, and transportation not all that it might be. The Missouri Pacific R. R. was short 300 cars for railroad coal in this field last week.

The labor situation is becoming acute again in view of the prospects of losing a large number of miners in the August draft, and only by the most strenuous efforts are the operators enabled to keep a large number of men from enlisting in the Navy in order to evade being drafted in the Army. Somewhat similar conditions exist in the Duquoin field.

In the Harrisburg district, from which territory a small tonnage comes in to St. Louis, the conditions are worse in some respects than in the Carterville field, especially as regards water. Throughout both of these fields the power for the operation of mines is supplied by a public service company, and the service has been so unusually poor that it is also affecting the tonnage produced, causing dissatisfaction among the men.

Conditions in the Mt. Olive field are uniformly steady. There is little variance week after week in this field. The car supply is fairly good. The labor supply is affected as in other fields, but it is not quite so apparent.

The tonnage produced here about equals the demand. Although a large railroad tonnage moves from this field the same as from the Carterville and the Duquoin fields, it is not affecting the domestic deliveries.

In the Standard district there is a car shortage and a surplus of screenings from the mines that do have cars. Added to this is the unequal distribution of empty equipment, which still continues in the face of protests from mines.

The water shortage is also severe at some of the mines here. There is a surplus of coal at the present time in this field that is being moved to the Northern markets and also to towns in Michigan. Locally, St. Louis is pretty well supplied with domestic coal of this grade, and from now on for some time a larger movement of this coal can be expected to move to Michigan and Northern points.

There are no eastern coals of any kind coming in and very little Arkansas. Standard 2-in. lump is a little under the maximum Government price. It is selling as low as $2.35 and $2.40 while screenings are around $1.65 and $1.70. All other sizes from all other fields are bringing the Government maximum. The Government maximum price here is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....
No. 3 nut	2.55@2.70	2.55@2.70	.....
No. 4 nut	2.55@2.70	2.55@2.70	.....
No. 5 nut	2.05@2.20	2.05@2.20	.....
2-in. scrgs	2.05@2.20	2.05@2.20	1.25@1.50
3-in. lump	.....	.....	2.25@2.40
2-in. lump	.....	.....	2.25@2.40
Steam egg	.....	.....	2.25@2.40
Mine run	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1	2.75@2.90	2.75@2.90	.....
No. 2	2.75@2.90	2.75@2.90	.....
No. 3	2.55@2.75	2.55@2.75	.....
No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

SEATTLE

State warned to lay in a supply of coal. Coal dealers required to secure licenses. Curtailment of power to save fuel is started. New mining operations discouraged.

If Washington or British Columbia coal is needed somewhere else it will be ordered sent there by the fuel administration, if fuel oil must be withdrawn and coal substituted, or if wood or other fuel can take the place of coal such action will be taken according to A. W. Calloway, director of distribution who has been investigating methods to speed up coal deliveries. The fuel shortage it is believed is going to be felt more next year than this winter and there is no way to avoid this winter's shortage.

Coal buying and distribution in the Northwest is to be readjusted according to Mr. Calloway. California contends it cannot get enough British Columbia coal and must therefore depend upon Wyoming and Utah. Portland argues that it must have Utah coal because it cannot get Washington coal. In eastern Washington consumers are drawing upon Montana and Utah for coal that should be supplied from this state or the Crows Nest fields of British Columbia. Mr. Calloway therefore believes that Washington is going to be compelled to supply her own needs and the needs of steamships here. This will release British Columbia coal which stands shipment better to San Francisco.

Retail coal dealers of the state have been required to register not later than Aug. 15. About 600 coal dealers are affected in the state. The registration is considered necessary for proper distribution, the control of the retail market situation and the securing of reports from retail dealers in the stocks on hand and the amount of coal handled by them.

General Statistics

NORFOLK & WESTERN TONNAGE

Coal tonnage from mines on the Norfolk & Western Ry. and from other railroads, for the month of June, 1918, were as follows:

From	Net Tons
Pocahontas Field	1,511,208
Tug River Field	305,025
Thacker Field	275,267
Kenova Field	96,098
Clinch Valley Field	138,467
Other N. & W. Fields	14,090
Total N. & W. Fields	2,340,155
Williamson & Pond Creek R.R.	183,556
Tug River & Kentucky R.R.	56,842
All other railroads	99,663
Grand total	2,680,216

Your Troubles

BY FLOYD W. PARSONS

A LOT of men and women continue to talk of their troubles and are grieved because the world doesn't stand at attention while their distress is relieved.

In America today there are countless people who look out on the horizon of their lives and, seeing a glow-worm, think it is a conflagration.

The fact that the fate of all humanity now hangs in the balance is second with them to the fact that one of the children is sick and the mortgage is due.

Why, man, do you not know that all former standards for measuring happiness and sorrow have been destroyed? Mrs. Smith next door has a wonderful son already sleeping in a grave in France, and Mrs. Jones across the street has a Red Cross daughter destroyed by a Hun bomb and buried in alien soil. What are your troubles to these?

You say that your business has been cut in half. Do you not know that hundreds of corporations have had to close up entirely due to the war? You cry out that the cost of your everyday necessities is abnormal. Are you not aware that more people have died of starvation in Europe and Asia this year than have succumbed to enemy bullets?

This is no day to whine and practice self-pity. It is a time that calls for decision and action. All worthwhile things are difficult. We learn by trying. Every day we delay our fight means a stronger enemy. And while we are hammering away, let us grin; there is a big difference between a grin and a smile.

The trouble is not our inability to bear adversity, but rather our inability to forget prosperity. Let us think more of the unconquerable spirit of the people who inhabited devastated Belgium, and we will be less conscious of our own trifling sacrifices.

Sorrow, like ill weather, comes without being sent for; but it will pay no debt and add nothing to the force of our effort. We might as well try to catch the wind in a net as to expect victory from a nation of weepers. It is our sacred duty to strangle the grumblers and mourners.

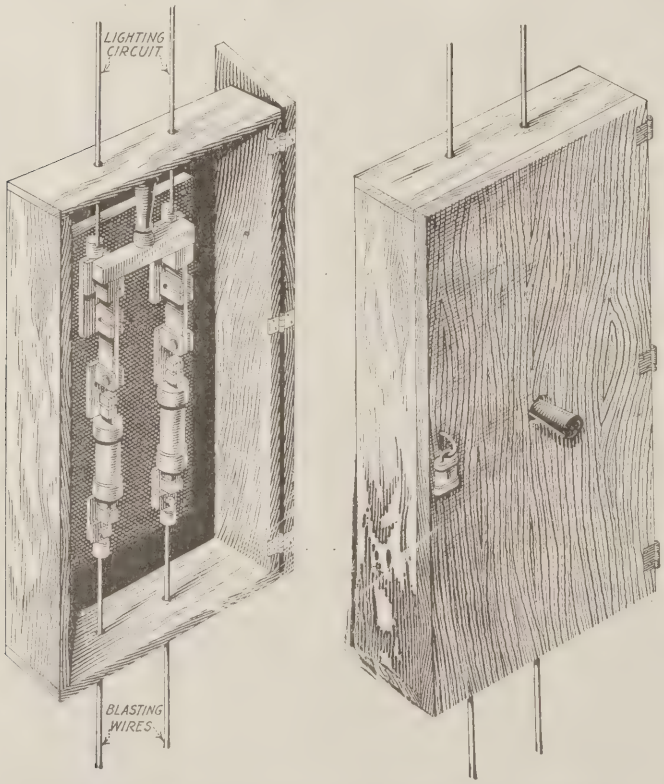
Griefs appear swift and remedies slow, but time tames the greatest sorrow. No mine or mill can set a new high figure for production if the men working there are morose and dreary.

Let us chase away the joy slacker. We must pool not only our material forces, but our glee forces. The man who holds the ladder is as bad as the one who climbs up it into your house and steals your goods. Any person in America today who goes about shrouded in gloom is as much a member of the Kaiser's army as the surly Prussian who carries a gun.

We are up against a de-humanized nation, a country whose soul has been shriveled and benumbed by the poison of hate and self-worship. We are fighting a people devoted to scientific barbarism—a government whose record of broken treaties and hideous cruelties goes back as far as its history. In order to win and forever silence the Huns and their Kaiser, who impudently anoints himself as the "Sword of God," we must forget our petty troubles and present a cheerful nation behind a cheerful army.

Grin and Work and Fight.

IDEAS AND SUGGESTIONS



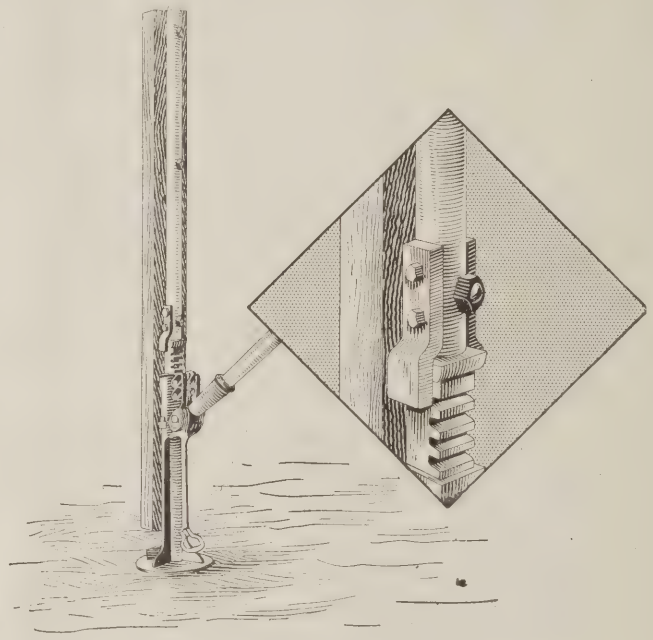
Blasting with the Lighting Circuit

BY THOMAS J. PASCOE

The following method of blasting, which is practiced in a mine in the vicinity of Norway, Mich., is sure to explode every hole: The current is taken from a 110-volt lighting circuit, and the charge is fired by means of a single-throw knife switch, connected as shown in the illustration. The switch is provided with fuse plugs. To explode 15 holes, a 10-ampere fuse is required. The blasting wires are so connected with the switch that, by closing the latter, they are cut into the lighting circuit.

The switch is placed in a wooden box, with a hole cut in the door, as shown. When the door is closed, the handle of the switch projects outside. This is done so that the miner may know positively that the switch is not in contact with the live wires before he attempts to connect his blasting wires to the charge. Otherwise a serious explosion may occur.

The miners prefer the method detailed to the old way with batteries, as it never fails to explode every



KNIFE-SWITCH USED IN EXPLODING CHARGES

hole at the proper time. The switch box should always be kept locked, and the key be given to the man responsible for the blasting. The knife switch should be placed with the live connections up. Then in case the door should be left open, and the handle drop, it would not come in contact with the live wires.—*Engineering and Mining Journal.*

A Quickly Adjusted "Jack-Prop"

BY HARRY GOODNOW
Du Quoin, Ill.

When a fire is raging at the face of an entry or room the first efforts put forth are to advance a canvas brattice up as close to the seat of the fire as possible in

THIS JACK-PROP IS RAPIDLY ADJUSTED

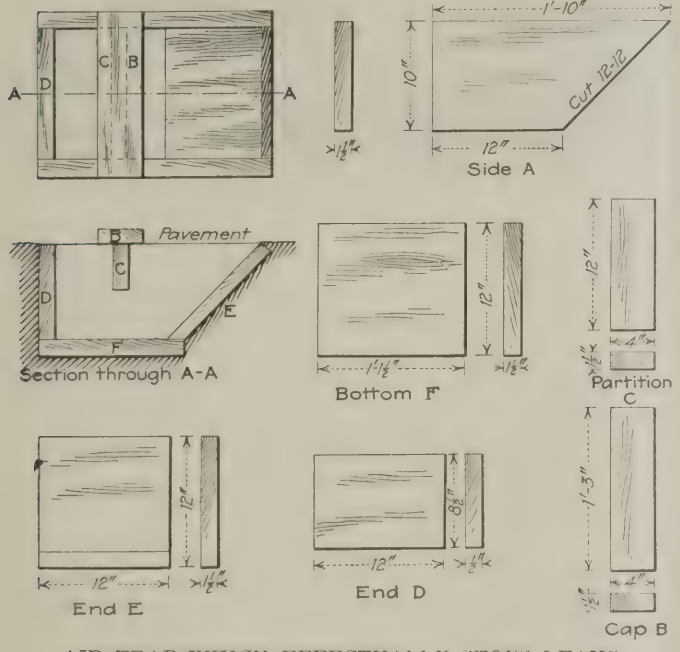
order to clear away the smoke so that the actual work of putting out the conflagration may commence.

How many practical mining men who read this have carried, into the suffocating smoke, a prop and tried to set it only to find it too long or short. Then with lungs ready to burst a hurried effort is made to guess at or measure the proper length, the heavy timber is hauled out and replaced or cut into supposed size, when another effort is made to set the right length of prop, which goes into place—maybe.

To obviate these troubles and delays a "jack-prop" was devised (as shown in the accompanying illustration). This is composed of two parts, as its name implies, any jack and a piece of pipe socketed to fit the top of the jack. This pipe has a wooden strip bolted to it upon which to nail the canvas.

A supply of these pipes, easily made by the mine blacksmith, and of different lengths, can be kept in a car together with canvas, fire extinguishers, etc. Upon the alarm of fire one man with a mule can take in this car, while another, acquainted with the mine, can quickly gather a few jacks to keep things moving.

Of course, these "jack-props" can be replaced with common props as soon as the smoke is cleared out, thus allowing a few used over and over again to carry the canvas an indefinite distance.



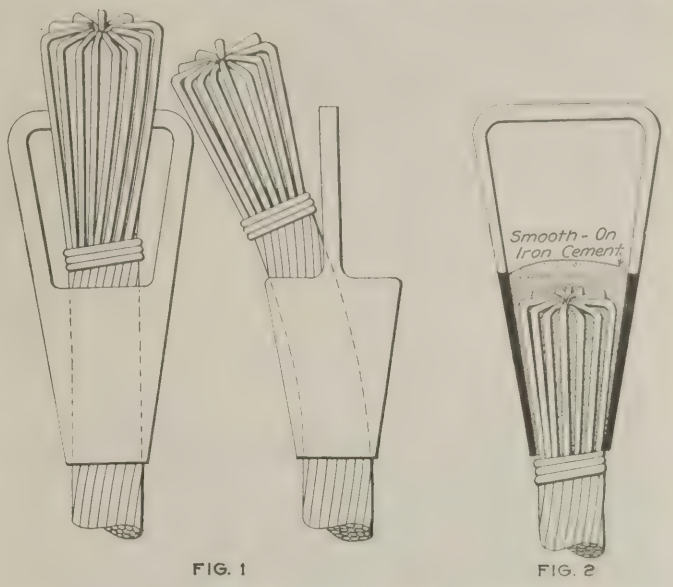
An Effective Air Trap

The old rhyme about "Little drops of water, little grains of sand," etc., might, so far as coal mining is concerned, be paraphrased somewhat as follows: Little drops of water, Running as they can, May mean a mighty air leak, And perhaps a fan. The air trap here described will effectually stop one kind of air leak that is at times quite troublesome.

One advantage of the construction shown in the accompanying illustration is that when the vertical side for the box is placed toward the flow of water a fall is formed that tends to keep the sediment in the bottom stirred up and washed out over the slanting side. Furthermore, where the flow of water is unsteady or intermittent, the trap stands full of water and prevents leakage.

A trap of the dimensions shown is large enough to handle the discharge from an 8-in. pipe and an air pressure up to 4 in. of water. For a greater volume of water, the box may made longer. Confining each side or member of the box to one piece of plank lessens the number of joints that are liable to leak.

The top of such a trap should be set even with the bottom of the ditch carrying the water. The slanting or discharge side should be so placed that a shovel may be used if necessary to clean out the box.



AIR TRAP WHICH EFFECTUALLY STOPS LEAKS

Tile bends are sometimes used in place of these traps. However, there are less satisfactory than boxes similar to the one shown, as they are more difficult to clean and more liable to break.

New Way of Socketing Wire Ropes

Many ropemen who have experienced difficulty in making a satisfactory joint when placing a forged socket on the end of a wire cable will doubtless be interested in a new method developed by John T. Willison, of Ambridge, Penn. Mr. Willison, who was testing 19-strand cables for tensible strength, was particularly interested in making a joint which would be stronger than the cable itself. After trying several methods unsuccessfully, the joint failing in each case before the cable was loaded to capacity, he finally conceived the idea of securing the cable in the socket with iron cement in the way shown in the illustration.

The cable end was first passed into the socket, as shown in Figs. 1 and 2. One of the outside wires was

FIGS. 1 AND 2. METHOD OF PASSING CABLE END INTO SOCKET

untwisted and wrapped tightly around the others. Above this wrap the remaining wires were untwisted and belled out as shown, and the ends turned down. "Smooth-On" Iron Cement No. 1 was mixed with water to a smooth putty-like consistency, and the socket packed closely with this material. The cable was then pulled firmly into place and the cement allowed to metallize. In metallizing, the iron cement expanded to such a degree that it completely filled the spaces between the wires and between the cable and the socket shell and thus wedged the joint securely. A firm union resulted, which, on test, proved to be stronger than the cable itself.

A bunsen burner can be used to show how mixing air with a flame affects combustion. When the air supply is turned off the flame from a bunsen burner is luminous. Its luminosity is due to incandescent particles of solid carbon resulting from the decomposition of hydrocarbons in the gas. The interior of the flame contains no oxygen to burn the hydrocarbons, and they are decomposed by heat into hydrogen and carbon. When the air is mixed with the gas as it enters the burner, the flame is nonluminous and has a well-defined inner cone. In this inner cone the oxygen of the air combines with hydrocarbons of the gas, producing H_2 and CO, which burn on the outer envelope of the flame. The reactions in the presence of oxygen produce gases that are easily burned, whereas the carbon produced in the absence of air is difficult to burn. Similarly, air mixed with volatile matter in the furnace before the tar is decomposed by heat may produce a larger proportion of combustible in the form of gas and less in the form of carbon.—*Bureau of Mines Bulletin No. 135.*

Orient Mine of Franklin County, Illinois

By GEORGE W. HARRIS
Editorial Staff "Coal Age"

FIG. 1. ORIENT PLANT OF THE CHICAGO, WILMINGTON AND FRANKLIN COAL COMPANY.

IF ALL the 324 commercial shipping mines of Illinois would produce as much coal in a year as the Orient mine of the Chicago, Wilmington & Franklin Coal Co. did last year, this country would be provided with one-half of the whole amount of bituminous fuel needed to supply 1918 requirements. Illinois is a great coal state and has some wonderful plants. The Orient mine is about 3½ miles northwest of West Frankfort, in Franklin County, Illinois, where big production is taken as a matter of course.

Standing on the hilltop adjacent to and overlooking Orient town, a person can readily see some of the big producers of this famous section. There are 14 mines around Orient, within a radius of about seven miles, which are producing 50,000 tons of coal daily. Among those participating in this good work are the Old Ben Coal Corporation plants near Christopher to the northwest; the U. S. Steel Corporation's Middle Fork, Benton Coal Co. and Chicago, Wilmington & Franklin mines at Benton on the northeast; the Byproduct Coke Corporation plants, Old Ben No. 8 and No. 9, and West Frankfort mine around the town of West Frankfort on the southeast, and the Ziegler property a few miles west. For the year ended June 30, 1917, this remarkable group of mines, including Orient, produced over 9½ million tons of coal, which was one-eighth of the total production of the state, while these 15 mines were only the 1/22 part of the 324 commercial shippers of Illinois.

The Orient mine is located on a 12,000-acre property, on which two additional plants of about the same capacity as the existing mine will be located. The No. 6 seam here runs from 9 to 12 ft. thick, and if it persists over the whole tract at an average thickness of 10 ft., the property will contain about 212 million tons of coal of this seam alone. It is expected that the new plants will incorporate some of the latest ideas in development which have come to be considered especially applicable to mining in Franklin County. The underground workings will also (similar to Orient) include isolating panels, which are most desirable in case of fire in the mine or an explosion taking place.

On Nov. 12, 1917, the Orient mine made its record run (which is also the record for this field) of 5508 tons of coal dumped in eight hours—this on a single-cage hoist. Needless to say, the cage is the self-dumping type; it is the Olsen pattern, made by the Eagle Iron Works, of Des Moines, Iowa. On the day the writer was at the plant 4900 tons were hoisted in eight hours; this coal was loaded by 441 men, or an average of about 11 tons per loader. In the year ended June 30, 1917, this mine shipped 1,100,000 tons of coal in 272 working days or part days that the mine operated, or about 4050 tons per day on an average. A number of conditions are necessary to enable a record run to be made, conditions which seldom prevail on many consecutive days. Car supply and labor have been erratic for the past year or so, making it increasingly difficult to even maintain normal production let alone record tonnage even for short periods.

The hoist at the Orient tipple is 600 ft. from the landing at the bottom of the shaft to the dump; the dump is 80 ft. above the surface. The No. 6 seam mined

here runs from 9 to 11 ft. in thickness and carries the characteristic blue band, which runs from ½ to ¾ in. in thickness at about 1½ ft. up from the bottom. The bottom rock is fireclay and the top a shale. The latter does not stand well when the coal is removed, making it necessary to leave up about 2 ft. of top coal in the rooms (at least until the rooms are finished) and 3 ft. in entries as a roof. Near the top of the No. 6 coal in Franklin and Williamson Counties is a persistent parting, at which the coal of the main bench easily separates from the top coal; these two benches vary in thickness. At some operations the top bench is the best coal in the mine, the ash running from 3 to 3½ per cent., while the ash content of the lower bench may run from 6½ to 9½ per cent. The heating values of the two benches are in inverse proportion to the ash content, the top bench having the greater heat values when the ash content is lower than in the bottom bench.

From the operator's standpoint nature seems to have favored Franklin and Williamson Counties doubly, in the sense that the coal is thicker than in most other sections and the values of farm lands are as low as any, and considerably lower than in most of the coal-bearing sections of the state. The greatest depth of cover over the No. 6 bed occurs in this general section. Damages for injury to surface would be much more serious in the case of mining a thick seam with little cover where the farm values were high than with low-priced land, as great disturbance to surface would inevitably take place on removal of such a thick bed with little cover.

The room-and-pillar panel system of mining is used at the plant in question, as shown in Fig. 2, which includes a portion of the mine west of the shafts. The rooms are turned on 40-ft. centers—18-ft. pillar and 22-ft. room; they are worked to a depth of 250 ft. Each panel has 16 rooms on each side of the double stub entry. A pillar of coal 20 ft. wide is left between the ends of finished rooms, and the main entries are protected by pillars 150 ft. in width. The 16-room panels are separated by 50 ft. of solid coal. Thus each group of 32 rooms has no connection with the balance of the mine, except where the stub entries connect with the east and west main entries. The shafts are protected by a pillar of about 20 acres in area. The north and south mains are also on the three-entry plan up to the last parting, and double entry from that point to the boundaries. In

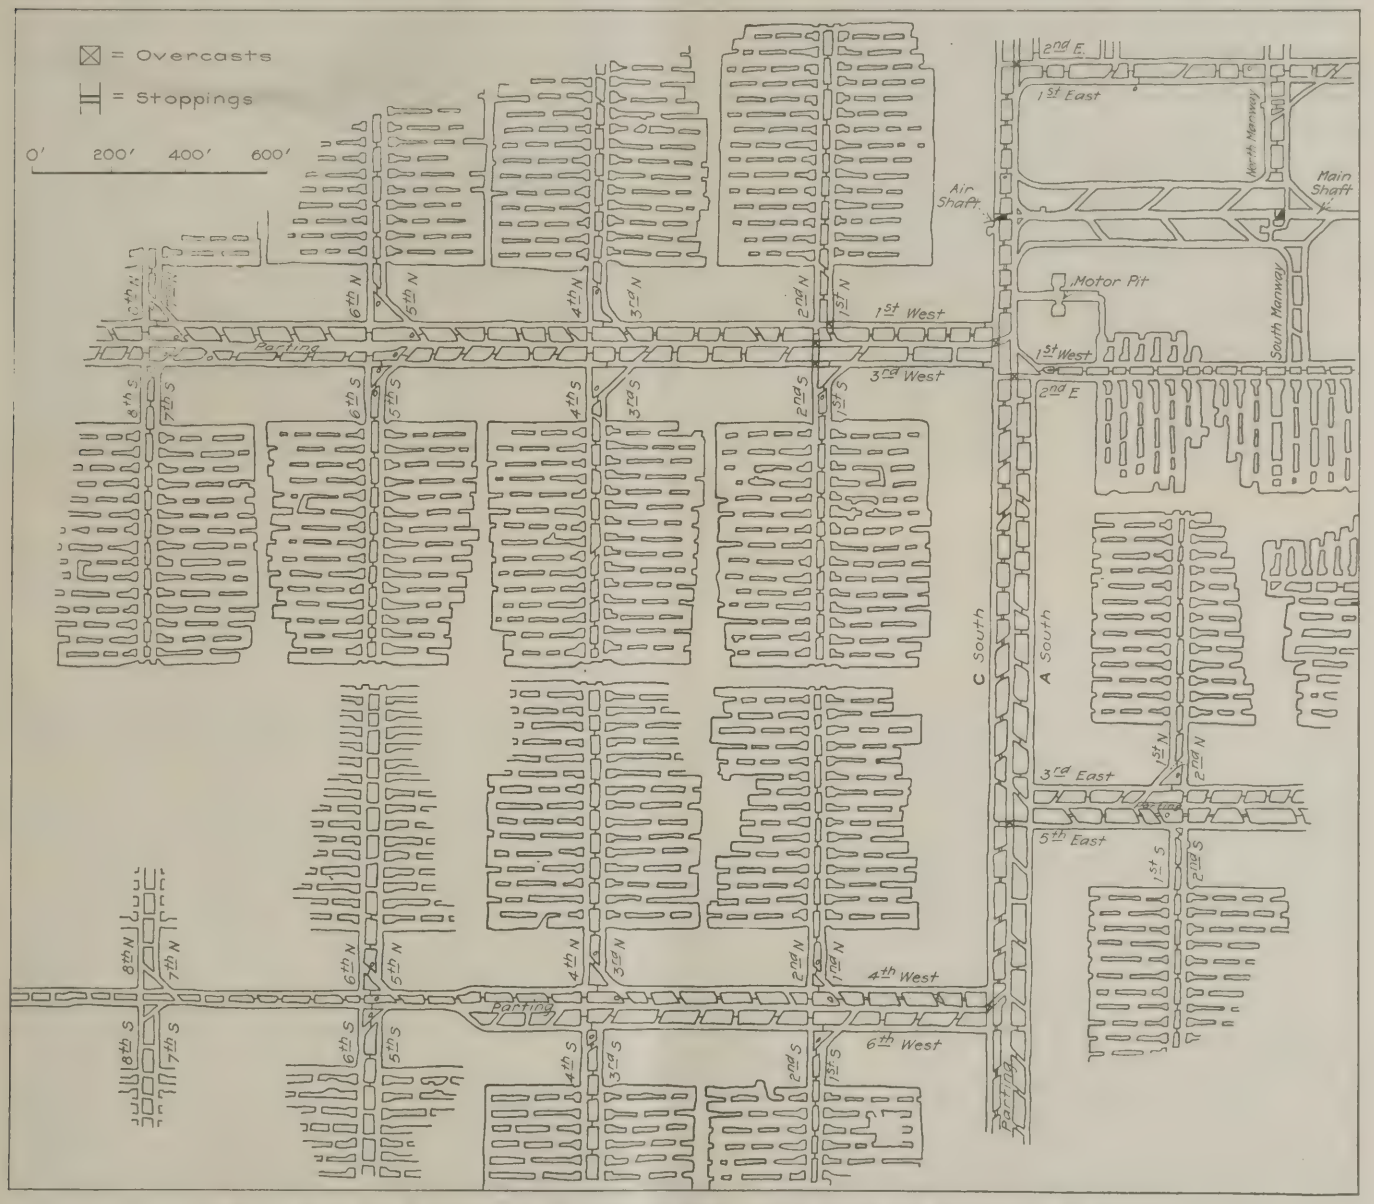


FIG. 2. MAP OF A PORTION OF THE ORIENT MINE SHOWING METHOD OF MINING

FIG. 3. MODERN SHAFT BOTTOM OF THE ORIENT MINE

the case of the triple entry, the center entry is used for haulage; the entry nearest the hoist shaft is the intake; the entry farthest from the hoist shaft and also the haulageway are the return.

As soon as panels are worked out they cave, break to the surface and close. The top coal and as much of the pillars as practicable are recovered, which gives an extraction of from 55 to 60 per cent. Mining in Illinois has undergone some changes in the last few years, perhaps the most notable improvement being the adoption of the panel system by the more progressive operators. Until quite recently little system was practiced by most Illinois operators. The result was most disastrous, except as regards temporary low cost of production. In 1909 George S. Rice, of the United States Bureau of Mines, wrote a paper for the American Institute of Mining Engineers on "Mining Wastes and Mining Costs in Illinois," in which he states: "The influencing conditions causing the great losses that are at present incurred are: (1) Cheapness of coal in place—that is, in the seam. (2) Low market prices, resulting from extreme competition. (3) Character of the seam, roof and floor as determining the method of mining. (4) Surface subsidence due to mining. (5) Interfaced boundary ownerships. (6) Carelessness in mining operations."

The great extent of coal territory offered for sale in Illinois resulted in transfers of coal rights at extremely low figures. Many mines were opened up, and the coal markets were greatly overstocked. All this tended to cause excessive competition and loose mining methods. Thick seams and a shale top which readily weathered encouraged the leaving up of top coal to save expense; this method, carelessness in mining operations and damage suits for subsidence of surface, all resulted in large loss of coal from varying causes.

Since 1909 conditions have changed. Coal lands have enhanced greatly in value, and there is a tendency to the acquirement of large holdings by big interests and development on an extensive scale. There was a growing interest in better methods of mining, greater recovery of coal, less loss through squeezes and more attention to the claims of those owning surface over mine workings. The outcome was an extensive Federal and state investigation into the whole situation and several reports on coal mining in Illinois, with special reference to percentage of extraction. A number of the large companies gave the matter individual attention and instituted reforms, possibly the most noteworthy improvement being the adoption of the panel system of mining and greater system as to proper proportion of pillar to room width and size of pillar to suit the various conditions of top.

With adjustment of the selling price of coal to permit of a respectable profit being made by the operator, another and important incentive was established for better mining. The map of the mine (Fig. 2) accompanying this article illustrates the panel system of mining, the advantages of which are too well known to need much comment. It is especially well adapted to the improvement of conditions in Illinois, in that it tends to localize squeezes which were of such frequent occurrence as to be notorious throughout the state.

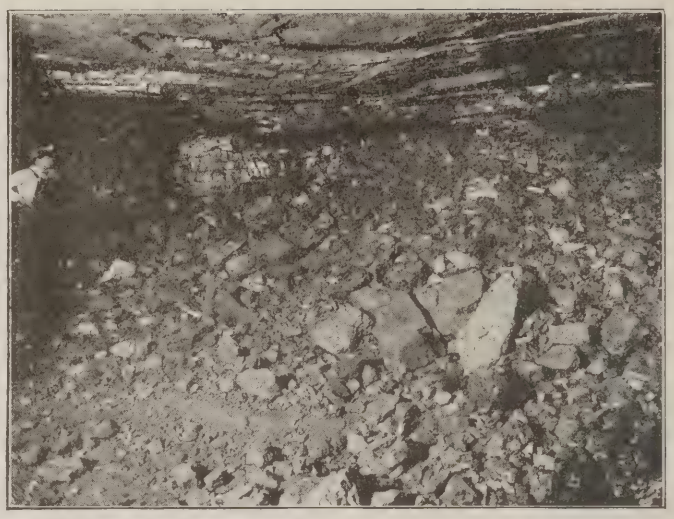
Among the interesting features of the Orient underground workings is the shaft bottom shown in Fig. 3. It is typical of the best development in shaft bottoms, in which I-beams support the roof and in turn rest on side walls of concrete. Concrete is a permanent investment in mines, especially in those workings which are as free from water as is the average Illinois mine, with sufficient cover to do away with much danger of large surface breaks. If mine water contains much

sulphuric acid it is said to be detrimental to ordinary concrete. Concrete is used extensively at and around the shaft bottom here, in cases where a permanent support of the roof is essential and the side walls should be kept up. When the side walls and top are whitewashed and the place lit up by electricity, the operations of moving cars and attending to various duties about the shaft bottom, partings and other busy underground places are not only much simplified but the chances of accident are greatly reduced. It seems to be easier to have a place kept clean and in order when the brightness of day is present. At the bottom a cager is in use which was made by the American Safety Device Co., of Bowerstown, Ohio—it is installed at many big producing mines.

The cars shown at the shaft bottom hold about 4½ tons of coal on an average; depending on the topping, they may hold five tons. The cars have Sanford-Day (Knoxville, Tenn.) "Whitney-wonder" roller-bearing wheels, which together with 45-lb. rails contribute to ease of haulage on main line roads. For such service three 15-ton, General Electric, "armor plate" locomotives are used. Six or eight-ton General Electric trolley motors are used for gathering cars, and 21 of these locomotives are necessary at this mine. It requires motive power to move 5500 tons of coal from face to shaft bottom in eight hours.

The coal is undercut by 35 Sullivan shortwall mining machines. This machine is shown at work in a room at the Orient mine, Fig. 4; it is about to make a sumping cut. The Sullivan Machinery Co., of Chicago, Ill., the maker of the machine noted, states that the use of mining machines in the United States has advanced from 545 machines in 1891, when 6,211,732 tons (or 6.66 per cent. of the entire output) was won by machines to 16,198 machines in use in 1911 (the latest year reported), in which 283,691,493 short tons (or 56 per cent. of the total production) where mechanically mined. Several feet of the upper part of the seam is left up temporarily to support the top in this mine as the rock immediately overlying the coal is a shale which gives trouble at certain seasons when unprotected. It is important that such top especially should not be disturbed more than necessary by shots. In machine mining shooting off the solid is practically eliminated, with its attendant injury to top, greater percentage of slack and less lump coal.

In Fig. 5 the coal has been undercut and the shots placed, and the shotfirers are represented as about to fire the shots by lighting the fuses. In the next illustration, Fig. 6, the coal has been shot down and is ready to be loaded. After a close inspection of Fig. 5, a person would not expect such good results as shown in Fig. 6, from the fact that the undercut has not been snubbed. But the shots evidently were well placed and gaged, for the coal seems to have been thrown out well and to be in good shape for loading. In Fig. 7 the loaders have about cleaned up the face of loose coal. The men shown in the room give a good idea as to the height of the seam. Also there is ample room between the car and the roof to permit of loading without much difficulty and to allow generous topping with lumps of coal.



There are about 700 men at the Orient plant, of which number 500 are loaders, 50 are machine men and 150 inside and top company men.

The town of Orient is about 3⅓ miles northwest of

FIG. 4. SULLIVAN SHORTWALL MINING MACHINE AT WORK IN ORIENT MINE

FIGS. 5, 6 AND 7. WORKING FACE AT THE ORIENT MINE
Fig. 5—Shotfirers lighting the shots. Fig. 6—Immediately after the shots have blown down the coal. Fig. 7—Loading the coal into cars

West Frankfort and the Chicago, Wilmington & Franklin Coal Co. runs a miners' train in to the mines in the morning and back to West Frankfort at night, for the accommodation of those employees desiring such service. About 60 per cent. of the men live in the town of Orient, including all office and other organization men. The town at the plant has all grown up in the last two or three years. The company has been building a number of frame houses for $1200 each down, and rents them to its employees or sells them on easy payments. Some 75 to 80 houses have been sold and sales are being made all the time. Also houses are being rented as fast as they can be built.

The vacant acreage so generally noticed in the vicinity of towns in mining regions is partly utilized in the case of Orient. A garden club has been organized, and prizes have been offered for the best garden. The benefits growing out of this activity are manifold. Outside of any material gain in garden produce is the improved appearance of otherwise waste ground about mining towns and the betterment of the morale of the community. Any movement which tends to attract the better class of labor and induce it to buy homes in the town at the mine will simplify problems of management.

A large capacity plant has different problems from one of small output. When the big producer lies idle, overhead charges quickly reach large figures and many employees are affected. During the last year or so, especially when transportation was erratic or entirely inadequate to the needs of operators, storage was resorted to in some cases to enable the mines to run with some degree of regularity. At the Orient mine the trestle system of storage was installed. On either side of this trestle are several parallel tracks on which two 20-ton clam-shell bucket locomotive cranes operate; these machines were built by the Link-Belt Co. When railroad cars were not available for shipping coal at the tipple it was loaded into 15 side-dump cars which emptied at the storage trestle. The 2-yd. clam-shell cranes piled the coal back from the trestle when necessary to permit greater storage, and also reloaded it into railroad cars at other times. Each crane has loaded 20 to 50 railroad cars a day on occasion. This scheme relieved the car-shortage situation and gave an opportunity to hoist; thus the 700 men at the Orient mine were given a chance to work full time. The trestle is kept as a reservoir; it is an elasticity proposition for steady output. The tonnage has sometimes been restricted by the men not coming out to work at times when they had an opportunity to do so. Shipment of coal from Orient can be made over any of the following three railroads, which supply cars to the mine: Chicago, Burlington & Quincy, Chicago & Eastern Illinois and the Illinois Central.

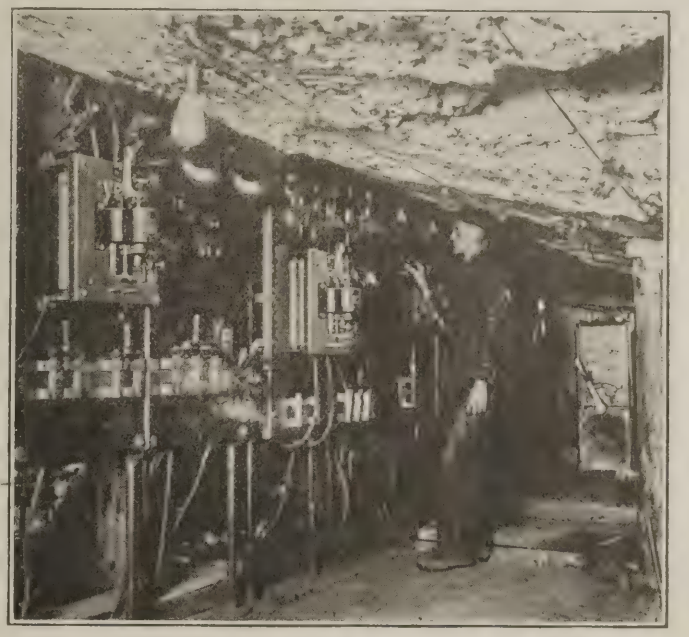
It is interesting to note the performance of the plant in question during the past few years, in which time it has passed from a new mine to the leading producer of Franklin County. In the calendar year of 1915 it shipped 500,000 tons of coal; in 1916, 830,000 tons; in 1917, 1,100,000 tons; and for the 12 months ended April 1, 1918, this mine shipped over 1,200,000 tons of coal. The best month's work was 120,421 tons. To make the fine record (5508 tons in eight hours) which this plant holds, it was necessary to dump three mine cars per minute, each car holding 4½ to 5 tons of coal. As an average daily tonnage of 5200 can be maintained, the management claims that the plant easily has a capacity of 6000 tons in eight hours. Larger capacity has been mentioned in the case of some plants now building, but a mine in Illinois able to achieve that record today would be considered a safe top-notcher, for a time at least. Among others the Orient people con-

sider that the main effort at present is to get coal—and then more coal—and they consider it a patriotic duty to see that everything is done at the mine to achieve this end.

In the recent sale of Liberty Bonds (the third loan) the company subscribed and then arranged a plan so that its employees could make easy payments for bonds subscribed for through the company. In the loan in question 1760 employees subscribed for $136,350 of bonds through the company Liberty Loan club; many others subscribed direct through banks and paid in full. A splendid showing was made on a wide distribution. Also in the Red Cross drives this company apportioned a part of its subscriptions to the counties in which it was operating mines, which subscriptions were heavily supplemented by the subscriptions of individual employees.

The Chicago, Wilmington & Franklin Coal Co. operates six other mines in Illinois. This company purchased mines A and B at Herrin, Williamson County, of the Chicago & Carterville Coal Co. The other plants are at Benton, Franklin County; at Virden, Macoupin County; at Thayer, Sangamon County, and at South Wilmington, Grundy County, respectively. The trademark slogan of Orient coal—"Hot and Bright Like Anthracite"—is full of significance and carries conviction, for the coal makes a fine appearance on cars, as it is clean and bright, stocks well, and is remarkably free from sulphur and less smoky than some grades.

The operating officials of the company are George B. Harrington, president and general manager; T. F. Holmes, general superintendent, and D. J. Carroll, assistant general superintendent. At the Orient plant Joseph Lewis is mine superintendent; G. M. Meagher, mining engineer, and John Rodenbush, mine manager. At the main office in Chicago, and also at the plant at Orient, the writer received the most courteous treatment in his quest for information, photographs and maps, and acknowledgment is here gratefully given for such favors.



Automatic Circuit Breakers in Coal Mines Effect Real Economies

Coal mines in the Central West which use electric power for operating coal cutters and haulage locomotives are finding economical applications for circuit breakers of the automatic reclosing type. At ordinary mines, with a power house or substation above ground feeding direct current to switchboards under ground, a single large breaker is usually installed at the station and another one for each branch circuit is installed at the underground boards.

To facilitate the operation of such a system a 1200-amp. automatic reclosing circuit breaker is installed in the substation, while below ground two 600- and one 400-amp. reclosing circuit breakers are placed on the switchboard. Each of the latter is connected into a circuit running far out into the workings. If now a short circuit or heavy overload should come on one of the 600-amp. lines on account of a "cave-in" tearing down a trolley wire or from some similar cause, the 600-amp. breaker would open the circuit and keep it open until the trouble was cleared up, whereupon it would automatically reclose. This would not interrupt the men working in places served by the other circuits. If the "cave-in" was not serious, the miners could make sure that the breaker would stay open by grounding the circuit with a chain or crowbar placed between the trolley and the rail. They could then clear, cutting the trolley wire if necessary. With this original ground cleared the chain or crowbar could be carefully removed, allowing the breaker thereupon to close of its own accord.

If the opening of a breaker were caused by a severe overload, and the breaker was of the manually operated type, work would have to be held up while word was sent to the switchboard to close the switch. With the automatic reclosing circuit breaker this delay would not be necessary, because as soon as the load was reduced to the value at which reclosure was desired the breaker would close automatically.

A low resistance shunt around the reclosing coil to the ground prevents the breaker from alternately

SWITCHBOARD INSTALLATION EQUIPPED WITH RECLOSING CIRCUIT BREAKERS

opening and closing at high speed under short-circuit conditions. It will either remain open or closed as conditions justify. The practice of installing an automatic breaker at the substation is usually followed because the attendant is not always right at hand and this unit is required to protect the station apparatus. The rating of this breaker is usually less than the sums of the ratings of those on branch circuits on account of diversity.

In some mines the installation of this apparatus is effecting real savings in money and in labor. One mine which formerly paid a man $5 a day to sit at its switchboard under ground and see that a 1200-amp. breaker remained closed has now replaced this arrangement with an automatic breaker at a total cost of $600. Thus in less than 120 days the mine had its money back, and during that time and ever since it had the productive labor of another man. The usual installations are smaller than this, requiring breakers of 100 to 400 amp., which can be installed for $135 to $150.

Coal Mining and Man Power

By F. A. POCOCK
Philadelphia, Penn.

SYNOPSIS—*At a time when the supply of available men is low and decreasing, and the output per man is also low, any means to increase the output per man should be given careful consideration. The longwall method of mining with certain modifications would appear to be a means whereby the output might be increased.*

DISREGARDING the anthracite region, for what I have to say does not apply there, this country is short of men who are versed in coal mining. The heads of departments are still on the job, and the thinking power of the industry still has its hand on the wheel and can be relied upon to steer the ship. Should this class fail, we still have the mining force of the Government to fall back on for the thinking. Possessed of this, is there no way of increasing the tonnage per worker? Can the thinker not make the worker more productive?

The following is submitted for careful consideration of the men who must do the producing. The fact that three tons per man per day is above the average production in the coal mines of the United States is in itself alarming. It means that the average man is only producing $9 per day, and that he is not working more than 70 per cent. of the possible days in the year.

Now there are a great many bituminous mines to which the following will not be applicable. At all events, however, it applies to the whole bituminous field of the State of Pennsylvania, and therefore to probably one-fourth of the national industry.

The time has come when the merits and shortcomings of the longwall method of working must be considered. Every phase of the system should be carefully taken into account. It is over 30 years since the Scott Co. in the Youghiogheny Valley section, under William S. Gresley, proved this system out. Mr. Gresley was a master in the art, but even he was hampered by the death of Scott. The interests succeeding Scott forced Gresley's resignation.

Cost of Mining Favors Longwall

Today we are in a totally different condition as regards electric power, locomotives, coal cutters, loading devices, and the lack of man power for the industry. Personally I have not the necessary data to give a résumé on the subject; but the costs of mining by longwall, as against the room-and-pillar method without electricity and all that it implies, was generally vastly in favor of the longwall. It therefore stands to reason that if the coal cutter can cut a face 300 ft. in length without having to move ten times, each of these moves involving the time necessary to travel an average of at least 200 ft. over mine rails, the loading of the machine, unloading and setting up again (which must involve at least one-half of the working time), the machine and its two men would be able to undercut at least twice the amount of coal that it can under room-and-pillar conditions. This does not only mean that the cutting expense will be reduced more than half, but that the same man power will produce twice the quantity of coal at twice the power cost. This will furthermore be achieved at one-half of the labor cost and at roughly one-half of the overhead costs.

May Be Feasible to Use Concrete Props

In longwall methods of working the roof must be supported near the face. This involves the use of considerable timber. It is customary not to set props and headpieces, but to build cribs allowing a slight slant from the side near the working face toward the waste ground that has been worked out. Here is where great economy can be practiced. It is necessary to allow the roof to come down gradually, so the lowest pieces can be short lengths of wood that will crush under the load. Above these well-seasoned concrete pieces can be used up to near the roof, where again the last packing, to insure an even load, can be of wood that will take the crush. As most of the concrete pieces will not be injured by the pressure they can be used again and again. There have been a number of references to the use of concrete in mining timbering, but it would seem that if it were adaptable anywhere it would be in longwall work, where all the crushing stress can be supported by adequate sections and the material be recovered and used repeatedly. The necessity for props will be reduced to the few places where the roof is locally bad and must be held to prevent accident to the men working the machines.

As the coal cutters will leave a fairly flat floor, the setting of the cribs will be an easy problem and the wood foundation and finish pieces can be made almost a standard as soon as the finished height of the seam is determined. In this way the cost of timber and timbering can be materially reduced from what it is in the room-and-pillar system.

There is no more heart-breaking work in a thin bed of coal than loading into the car, and there are no loading machines that will work in even a 4-ft. seam. There is, however, no difficulty in designing a conveyor that can operate in less than 2 ft. of height, nor any difficulty in driving a 300-ft. (center to center) length of such conveyor by electric motor. As this is fairly flexible, it can be on such a floor as a coal cutter will leave. It will be necessary to have height in the haulage road, and as these beds usually have a clay floor the cost of making the necessary height will be less by taking up floor than by taking down roof. This also gives the advantage that the top of the car will be little, if any, above the floor of the longwall face. Therefore the coal will not have to be loaded, and the conveyor end can be raised the

necessary distance to allow the coal not only to clear the top of the car but to be taken almost across it; also, the loading can be done without manual labor. It will be necessary to have a second machine working at an angle to the conveyor to load the coal broken down onto the conveyor, but as this can also be electrically driven, and of simple design, there is every argument in favor of its being built.

The method of handling the trip of cars will depend largely on the strength of the roof, on how far back this will stand up of sufficient height to allow the cars to be pushed beyond the loading point of the conveyor. This would of course be the cheapest method of handling the trip. But even if the roof is short and breaks close up, by using a small motor-and-rope transfer and a double track the switching of the cars under the loading end of the conveyor will be a rapid process if flat plates are used as a terminal instead of rails. By this means the loaded car can be sent out after the empty is brought up to its side, or slightly beyond, and the empty be hauled back under the conveyor, against a guide rail which will easily force it over if the wheel flanges are on a flat plate. Thus little, if any, time need be lost in switching the car to the loading point.

Fifty Men Secure 500 Tons a Day

A 300-ft. face in a 3-ft. bed, with a 6-ft. undercut will give 200 cu.yd., or roughly 250 tons of coal. From a haulage point of view this tonnage should be handled in eight hours. The coal cutter should also be able to make cuts of 300 ft. each in an eight-hour period.

It will therefore require two locomotives and two loading machines to give an output of 500 tons per day. The man power for the foregoing operations only will be:

Coal cutter	2	Locomotives	4
Loading device	2	Shot drillers	4
Conveyor control	2	Shotfirer	1
Car handlers	2		
		Total	17

At an average wage of $5 this will amount to $85. This would give a wage cost of only $0.17 per ton. The costs for track and timbermen, cleaning up and other necessary operations are not so easy to estimate, but if the foregoing cost items are doubled, there will still be a large factor left in favor of the longwall method of working.

The tipple, road and overhead costs will not be much affected, except that the road-repair cost may be slightly raised because the tonnage moved is heavier. At all events, here is a basis for considerable discussion. Practical mining men should consider the foregoing from their own standpoint and from local mining conditions; and see if they cannot modify it so as to secure local success. A greater tonnage per man when men are of the greatest value to the whole world is well worth securing.

One thought more. Assuming that it will take double this number of men to keep these 17 at work; or if, say, 50 men can secure an output of 500 tons per day, we will have raised the tonnage per man per day to 10 from, we will say, the best, or 4. In other words, this would mean an increase of 250 per cent. Is this not worth attempting?

Colorado Meeting of A. I. M. E.

The American Institute of Mining Engineers will hold its meeting in Colorado from Sept. 2 to Sept. 7, and the program will be as follows:

Sunday, Sept. 1

Registration at Brown Palace Hotel, Denver.

Monday, Sept. 2

9:00 a.m. Technical Session on Metallurgy.
Automobile trip to the ferro-alloy plant and other points of interest in Denver, followed by mountain trip.
1:00 p.m. Luncheon at Hosea Lodge in Genessee Park, Lookout Mountain.
7:00 p.m. Dinner at Country Club, Denver.

Tuesday, Sept. 3

8:15 a.m. Entrain for Colorado Springs.
11:00 a.m. Arrive Colorado Springs. (Headquarters, Broadmoor Hotel.)
12:00 noon Memorial to Dr. James Douglas.
1:00 p.m. Luncheon at Broadmoor Hotel.
2:00 p.m. Technical Sessions, Ore Dressing and Cyanidation; Coal and Coke.
Moving Pictures of Employment of War Cripples in Industry.
8:30 p.m. Reception and dance.

Wednesday, Sept. 4

All-day trip to Cripple Creek.
8:00 p.m. Technical Session, Geology and Mining.

Thursday, Sept. 5

8:00 a.m. Automobile trip to Pike's Peak.
2:00 p.m. Visit to Golden Cycle Mills.
4:00 p.m. Memorial Meeting for Members of the Institute who have given their lives in the Service of the Allies.
8:00 p.m. Technical Session, Petroleum.
Moving Pictures of Employment of War Cripples in Industry, especially in regard to Mining and Metallurgy.

Friday, Sept. 6

8:30 a.m. Entrain for Pueblo.
12:30 p.m. Luncheon at Minnequa Steel Works, Pueblo.
7:30 p.m. Banquet, Broadmoor Hotel, Colorado Springs.

Saturday, Sept. 7

Optional visit to Leadville and Red Cliff.

The program for the entertainment of the ladies is still in a formative stage and has not been announced. At the session on coal and coke the following papers will be read in brief and discussed: "The Byproduct Coke Oven and Its Products," by William Hutton Blauvelt; "The Use of Coal in Pulverized Form," by H. R. Collins; "Coal Mining in Washington," by F. A. Hill; "Carbocoal," by C. T. Malcolmson, with written discussion by W. R. Cox and N. W. Roberts; "Development of the Coke Industry in Colorado, Utah and New Mexico," by F. C. Miller; "Price Fixing of Bituminous Coal by the United States Fuel Administration," by Cyrus Garnsey, R. V. Norris and J. H. Allport.

In the combustion of coal the law of mass action manifests itself by the fact that in boiler furnaces considerable excess of air above the theoretical requirement is necessary to insure complete combustion within the furnace. If the air supply is reduced to nearly the theoretical amount the combustion is so slow that a large percentage of the gases may leave the furnace before they are burned.

Provincial Rights Dispute in Canada

By ROBERT DUNN
Victoria, B. C.

SYNOPSIS — *Title to a large part of the coal-bearing lands of Vancouver Island are in dispute. A review of the half century that has elapsed since the white man's occupation of this region reveals that all parties have apparently acted in good faith. There has, however, been an overlapping of the prerogatives of the Province and the Dominion.*

FOR many years, a bitter dispute has been waged as to the title to a considerable proportion of the coal-bearing lands of Vancouver Island, British Columbia. An event of recent date promises to bring this struggle into national prominence by plunging the Government of the Province of British Columbia into a controversy with the Dominion Government at Ottawa over the question of provincial rights.

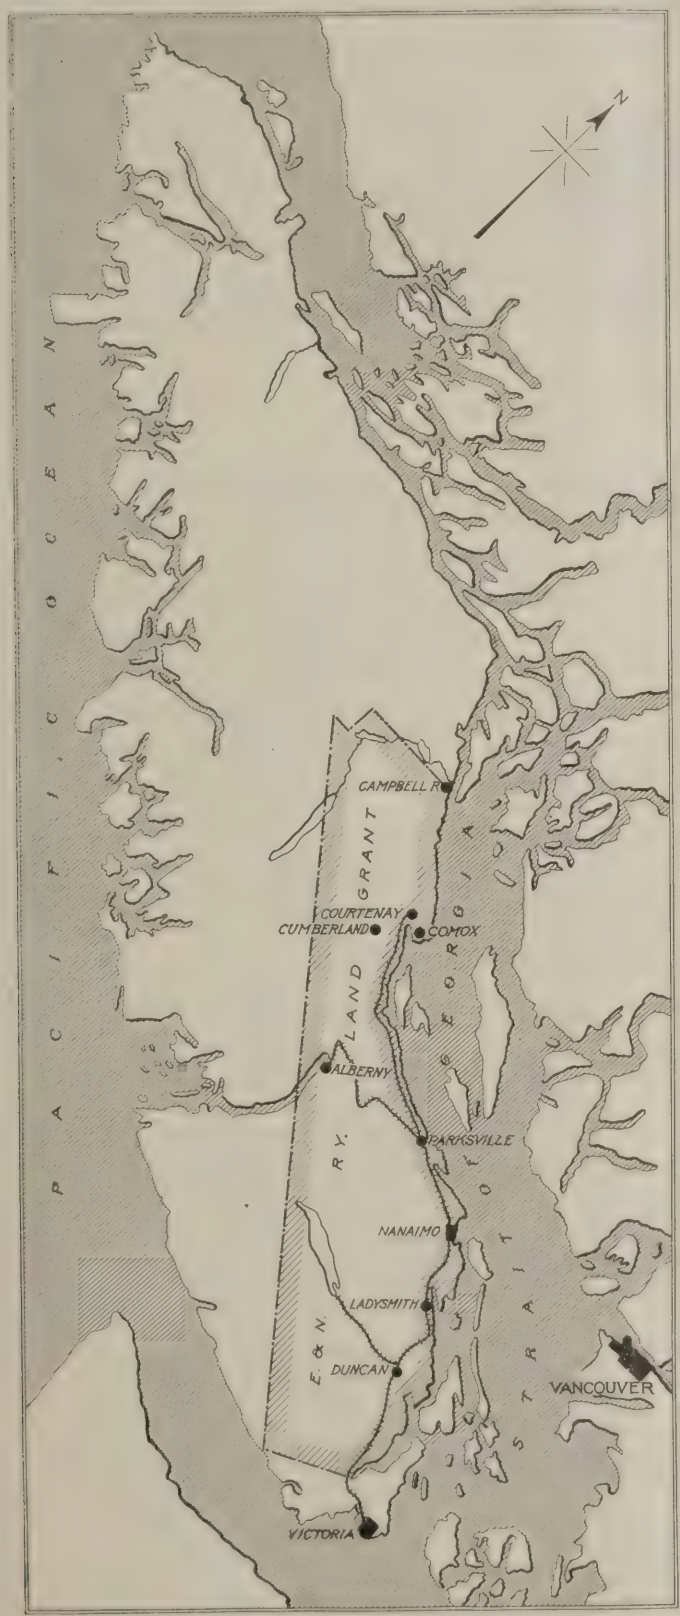
Meanwhile, to sum up the situation in a few words, the Canadian Collieries Co. (Dunsmuir) Ltd., finds its title to extensive island coal areas confirmed; the Granby Consolidated Mining and Smelting Co. is in a position of some doubt as to its proprietary right in coal areas, the development of which already has cost hundreds of thousands of dollars; while the early Vancouver Island settlers, who claim the coal rights in lands occupied by them in pioneer days and whose claims have been maintained by the Provincial Government, see ahead a continuance of the fight, with the issue shrouded in uncertainty.

Before going further let me explain, briefly, what is at stake. The accompanying map of Vancouver Island shows the Esquimalt & Nanaimo Ry. belt, stretching from the southerly extremity of the island northward along the east coast. Incidentally there will be found marked the chief coal-mining centers of Ladysmith, Nanaimo and Cumberland. This belt covers an area of 3296 square miles. It is one-fifth of the total acreage of Vancouver Island and its actual reserve of bituminous coal, to quote the 1915 report of B. D. Dowling, of the Canadian Geological Department, is placed at 1,060,000,000 short tons. With these facts in mind it is not difficult to understand the determined effort being made by the rival claimants.

The recent event referred to is the disallowance by the Dominion Government of provincial legislation passed early last year and known as "An Act to Amend the 'Vancouver Island Settlers' Rights Act, 1904.'" In other words the federal authorities have said to the province, in effect: "You have gone beyond your power in giving to settlers this opportunity to acquire the coal under the lands which they homesteaded. The title in question has been otherwise vested and the Act is *ultra vires.*" I understand that all this is meaningless and without significance to one outside British Columbia who never heard of the matter before, but it will be appreciated that, with the gantlet thus thrown down, it is more than probable that the province will take whatever measures are available to assert and maintain what it deems to be the legislative rights conferred upon its government when it became a part of the Canadian Confederation.

It is necessary in endeavoring to make the situation clear to look back over half a century. Vancouver Island then was a wilderness. There was a Hudson Bay post at Victoria, the capital of the province now, and a settlement at Nanaimo, B. C. Coal had been discovered near the latter town and at some other points. The late Robert Dunsmuir, who became the coal baron of western Canada, was the first to enter into coal mining in this section to any extent. Between 1860 and 1871 quite a number of settlers went on the lands, the title to which is now in dispute, and under the law of that day obtained freehold titles—that is, rights over the surface and under-surface values, with the exception of gold and silver, which minerals always were vested in the Crown.

Closed the Lands to Settlement



In 1871 British Columbia went into the Canadian Confederation and provision was made in the Terms of Union that a tract of land extending 20 miles on each side of a proposed railway running from Esquimalt (near Victoria) to Nanaimo should be reserved as a part of the subsidy to those undertaking the construction of the road. Accordingly the British Columbia government declared a reserve on these lands, which it is contended closed them absolutely to settlement. In 1884 British Columbia conveyed these reserved lands, the same as are shown in the illustration, to the Dominion together with "all coal, coal oil, ores, stones, clay, marble, slate, mines, minerals and substances whatsoever thereupon, therein and thereunder." In turn the Dominion Government assigned the lands, with its under-surface rights, to what is known as the Esquimalt & Nanaimo Railway Co., which concern, whose principals included the late Robert Dunsmuir and some capitalists of the United States, undertook to build the railway and did carry out its contract.

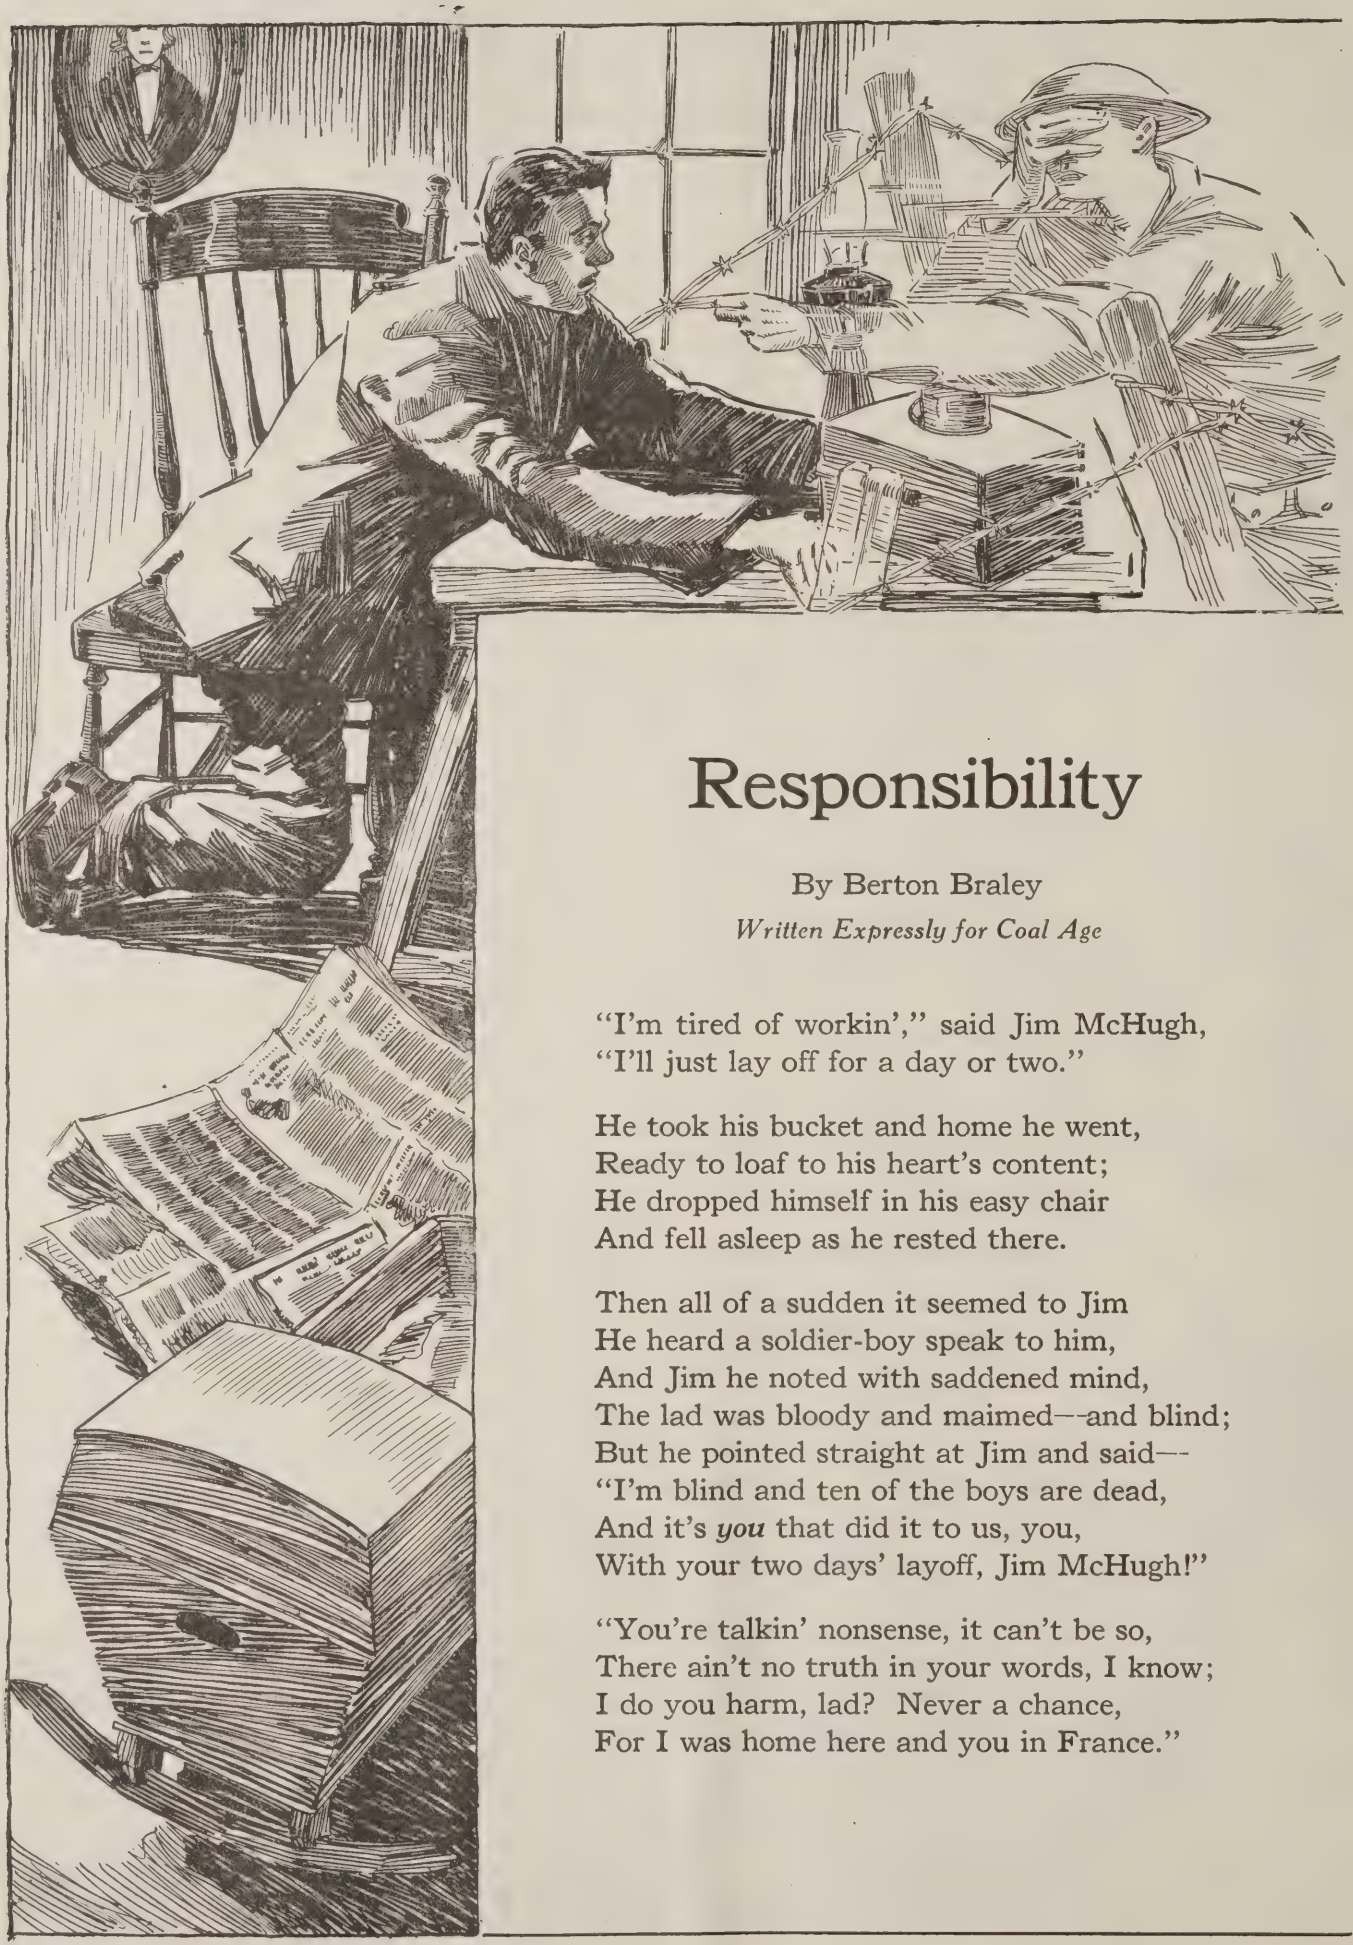
Subsequently, those who took up land in the belt when the reserve was supposed to be operative—that is, between 1873 and 1884—declared that the reserve was not valid because it was imposed in accordance with the Terms of Union, which provided that British Columbia should not alienate or sell any further portions of these public lands *in any other way than under right of preëmption, requiring actual residence of the preëmptor on the land claimed by him.* They advanced other seemingly sound arguments, and in 1904 the British Columbia legislative assembly passed the Settlers' Rights Act, which gave them a year in which to make their claims to the coal under their properties. Those whose rights were considered satisfactory were given provincial titles covering under-surface minerals, and the government agreed to support them should the company contest their legal rights.

The company fought, asking for disallowance at the

national capital and prosecuting a test case through the various courts of the land to the Privy Council, without success. Then an agreement was reached between the government and the company, the latter being recompensed to the extent of 20,000 acres of public lands, if it would leave the settlers in peaceful possession.

It was thought that this disposed of the matter, but not so. It developed that many settlers with as good claims as those who got titles had failed within the year to lay them before the proper authorities. They began clamoring for recognition, which the present government, in 1917, decided should be granted. And so came the Settlers' Rights Amendment Act of 1917, which has been disallowed. It simply extended to Sept. 1, 1917, the period in which registration of claims could be made. In that period 179 applications were made, covering, according to a statement issued by the company, 33,000 acres, about 90 per cent. of which refer to coal lands, and the greater part of which, it is believed, contain coal seams of commercial value.

MAP OF VANCOUVER ISLAND, SHOWING ESQUIMALT & NANAIMO RAILWAY BELT



Some of these claims were investigated by the provincial government and several were allowed, provincial title being issued. Two such titles have been purchased from the settlers by the Granby Consolidated Mining and Smelting Co., and on the land covered by them, situated a little south of Nanaimo, this company has erected its new coal-mining town, constructing houses for workmen, tipples and plant, driven three slopes and struck a splendid bed of coal, in one instance 14 ft. in thickness at the face. This firm, also on the strength of the newly developed coal area and with a view to doing its own coking at its smelting center at Anyox, B. C., is engaged in the installation of byproduct ovens. In short the whole investment represents an outlay of $1,000,000, to put it conservatively. Its embarrassment as a result of the Dominion government's unexpected action thus becomes clear.

In 1910, after the Esquimalt & Nanaimo Railway Co. had reached its understanding with the then existing provincial administration, it disposed of part of its lands, its coal mines, and further "all coal and fireclay in, upon, and under the said lands and control of the right to acquire all the coal and fireclay under the remaining lands in the Esquimalt & Nanaimo land belt." The purchaser was the Canadian Collieries (Dunsmuir), Ltd.

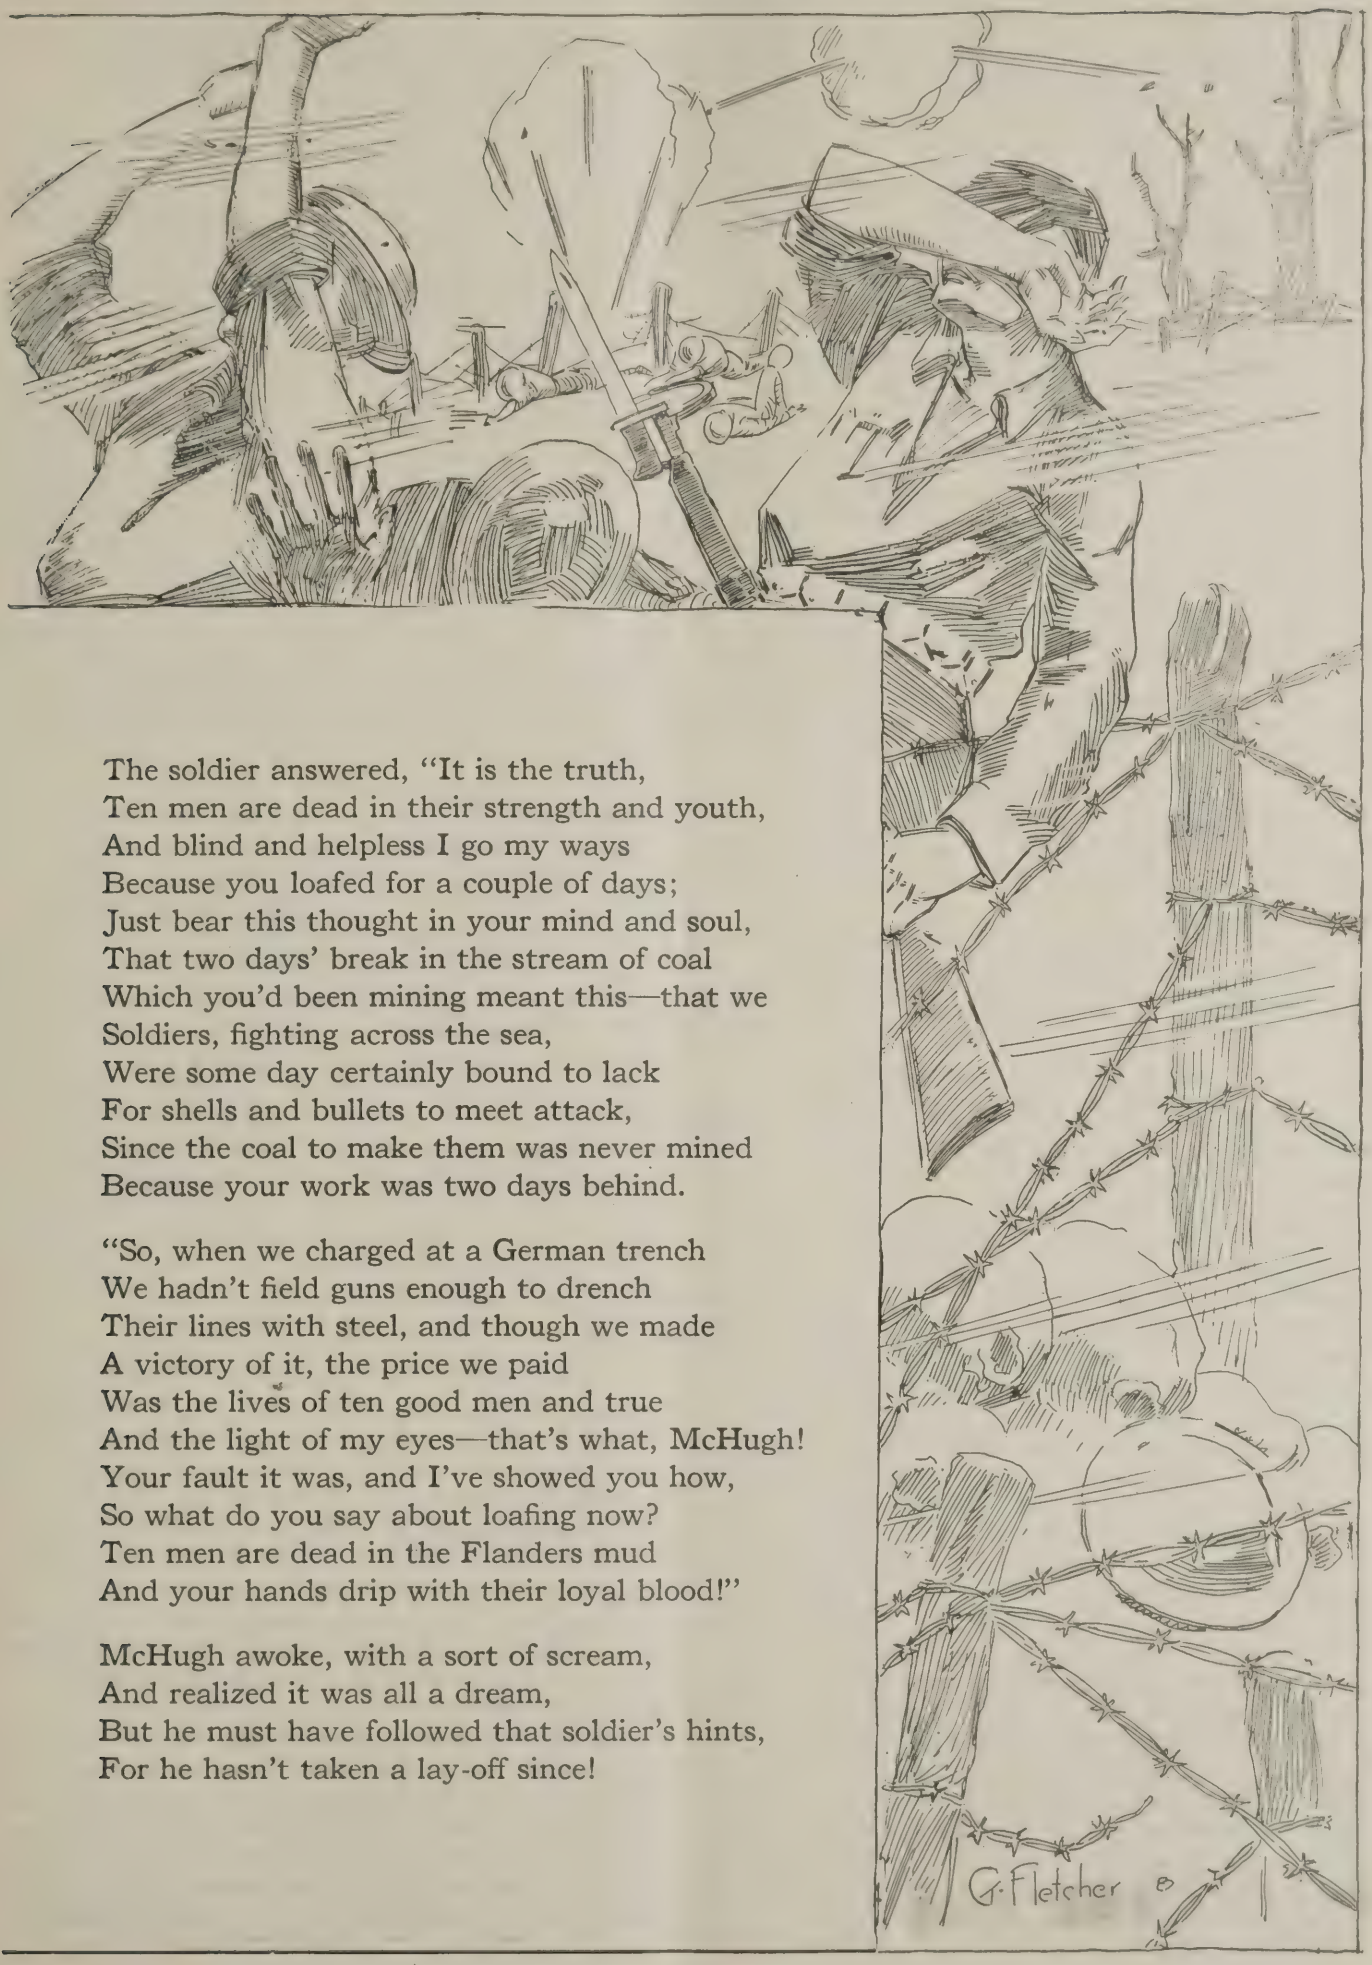
Having the property this company pledged it as security in the issuance of a bond issue of £2,054,800 (nearly $10,000,000) and in the sale of preference shares to the value of $5,000,000. One of its strong arguments, therefore, in asking that the Dominion government disallow the Settlers' Rights Act of 1917 was that it sanctioned the alienation of property to which it held title and which had been mortgaged to the investors of Great Britain and the United States to secure operating capital. This assertion, however, that confidence in British Columbia security among financiers would be shaken, was only incidental to the main contention that the settlers had no vestige of right in the property for which they were setting up a claim and that acquiescence in their demands would practically amount to confiscation.

What the government of British Columbia will do is as yet undecided, but it is considered likely that, apart altogether from the actual merit of the settlers' case, it will maintain to its utmost, on principle, the provincial jurisdiction over all matters relating to property and civil rights.

In Many Cases where coal has been lost in robbing it has been found profitable to open gangways for re-robbing. This would not be necessary if a systematic robbing of the pillars had been carried out.

Responsibility

By Berton Braley



Written Expressly for Coal Age

"I'm tired of workin'," said Jim McHugh,
"I'll just lay off for a day or two."

He took his bucket and home he went,
Ready to loaf to his heart's content;
He dropped himself in his easy chair
And fell asleep as he rested there.

Then all of a sudden it seemed to Jim
He heard a soldier-boy speak to him,
And Jim he noted with saddened mind,
The lad was bloody and maimed—and blind;
But he pointed straight at Jim and said—
"I'm blind and ten of the boys are dead,
And it's ***you*** that did it to us, you,
With your two days' layoff, Jim McHugh!"

"You're talkin' nonsense, it can't be so,
There ain't no truth in your words, I know;
I do you harm, lad? Never a chance,
For I was home here and you in France."

The soldier answered, "It is the truth,
Ten men are dead in their strength and youth,
And blind and helpless I go my ways
Because you loafed for a couple of days;
Just bear this thought in your mind and soul,
That two days' break in the stream of coal
Which you'd been mining meant this—that we
Soldiers, fighting across the sea,
Were some day certainly bound to lack
For shells and bullets to meet attack,
Since the coal to make them was never mined
Because your work was two days behind.

"So, when we charged at a German trench
We hadn't field guns enough to drench
Their lines with steel, and though we made
A victory of it, the price we paid
Was the lives of ten good men and true
And the light of my eyes—that's what, McHugh!
Your fault it was, and I've showed you how,
So what do you say about loafing now?
Ten men are dead in the Flanders mud
And your hands drip with their loyal blood!"

McHugh awoke, with a sort of scream,
And realized it was all a dream,
But he must have followed that soldier's hints,
For he hasn't taken a lay-off since!

Can Output Be Increased Scientifically?

By W. E. JOYCE
Sandy Run, Penn.

SYNOPSIS—*Various causes are ascribed by various people for the short coal production. Some writers say the great cause is the draft, others allege drunkenness among mine workers. Whatever may be the underlying cause the effect must so far as possible be rectified. It would appear that here a little modern science might be used to good effect.*

SPEEDING up production of anthracite coal with a dwindling force of operatives has resolved itself into a serious problem. To say that the failure to materially increase the output is due to the draft is as untrue as to say it is due to drunkenness among the miners.

That the draft is regarded by many mine managers as the greatest menace to future shipments is shown by the vigorous appeals being made to the exemption boards in all districts of the mining field.

That drunkenness is believed by many others to be responsible for the shortage of coal is shown by the numerous letters appearing in many public journals and magazines.

There is no doubt of the matter being serious, and to secure a satisfactory solution for all concerned it demands consideration that will be free from bias of every kind.

Even Outsiders Are Interested

People outside the coal-producing area are quite as much concerned as those depending upon it for a livelihood. The people of the mining communities who have sent their sons to the front are already violently objecting to having placed in the hands of coal-mining officials the right to say who shall or who shall not be excused from military duty. This is virtually what is being asked of exemption boards at the present time on the ground that certain employees are absolutely necessary to the production of coal at different mines. In objecting to granting such privilege, it has been pointed out that already where exemption or deferred classification has been granted on appeals of certain mining officials, their representations as to the real value of the man to production of coal were greatly overdrawn. In fact it has been shown that in a certain case an individual upon whom it was claimed the production of a mine largely rested was not employed at the mine at all, but was engaged doing chores about the bosses' homes and worked as a gardener for the widow of a former superintendent.

Another case is cited as showing the cupidity of officials. A man who was seeking an increase in wages was put off from time to time. When he last called and asked about his promised increase the official said to him: "We have done better for you than granting you a raise; we have had you placed in the deferred class by the exemption board."

There was widely published in coal-region papers during the recent past an extract from an article originally appearing in a New York publication which purported to show that drunkenness among coal miners was rampant; that drinking bouts and protracted orgies were the vogue in all mining towns. Of course, the real cause for coal shortage was thus traced.

It is evident that the situation calls for more intelligent treatment. Chairman Hurley of the Shipping Board in his address before the coal operators meeting in Philadelphia recently, pointed the way in a definite manner when he likened the mining situation to conditions in the shipbuilding industry when the Government took hold. He said inefficiency among department heads was responsible for 50 per cent. of the trouble, and it was necessary to reorganize from the top down.

It is not recorded in reports of the meeting that his remarks were applauded. They were probably too personal but highly pertinent. It is singular, too, that no reference to Mr. Hurley's solution appears in the discussions that have since occupied much space in trade journals and other publications.

The people of the mining districts not directly connected with the mining industry are, perhaps, in position to best weigh the question. There are difficulties developing, even now, that threaten to complicate the problem of production by bringing discord among the miners themselves. Among these is the refusal in many instances of laborers to work on the day-wage plan with a contract miner.

That miners are not delivering coal on a 100 per cent. basis is unquestioned. But how to improve this without dislocating the means by which present output is secured requires the application of a sympathetic interest not readily found outside the mining field itself. Certainly it will not come from the radical exponent of the draft nor of the drunkenness tales, so that in consideration of finding a means for reaching the best solution, the board selected should not be without representation from the mining section itself.

Charge of Drunkenness Is Resented

People of the mining communities resent the charges of drunkenness as a gross libel. Failure of men to report for duty on account of liquor forms but a small percentage of the existing absenteeism. At one colliery recently when 19 men were reported absent on the day following United Mine Worker President Hayes' appearance on a speech-making tour, urging men to renounce pleasure during the war period, it was found that 11 of the 19 men absent were teetotalers. Funerals, picnics and personal affairs formed the burden of excuses assigned.

And this will sum up the situation in a general way as far as drink is concerned. It is safe to say that drinking among railroad men is more extensive than among coal miners, and when one considers the cosmopolitan class of workers following mining it is quite astonishing to find such a low percentage of drinkers among them. During the heavy demands for coal last winter when piteous appeals were sent out for coal

supplies and urgent calls made by war projects, it was a weekly occurrence to find on Monday mornings several extra train crews crowding the trains bearing coal diggers to their places of employment. The extra crews were being sent to yard centers to take the places of railroaders who failed to report for work or requested leave of absence on various pleas.

These things happen within the mining district. Is it any wonder the people resent the calumnies constantly being circulated about their home sections? The iron and mill districts of the country are far more prolific in furnishing "horrible examples" for the temperance advocates than the coal mining communities, yet these districts are not being everlastingly traduced and villified as are the mining communities. This, however, is not said in defense of liquor drinking in any form. It is set forth rather as a deterrent upon the disposition among many magazine contributors to magnify conditions. We should have cold, hard facts upon which to build a decision when considering the question of military draft, drink and coal production.

In an open letter recently sent out by the manager of a large coal company, the statement was made that the operating force had been reduced 40 per cent. during a given period. An analysis of this falling off disclosed the fact that of the total number of men who had left the company's employ 20 per cent. had been drafted or volunteered for military duty while 80 per cent. had left to work under conditions more desirable elsewhere. It is significant that the treasurer of this same company appearing before a Federal Commission a short time ago declared under oath his company had made a profit of 50 per cent. in mining the previous year.

Wages Are Not All

Considering the hours of work about coal mines, the question of wages is not alone the cause of men seeking employment elsewhere. For the son of a coal miner to try and better his condition in life by going into some other industry, surely is not wrong. He has ambitions and these ambitions are invariably fostered by his parents. If conditions at the old home are not congenial can he be blamed for going where he finds them more desirable?

The company making a 50 per cent. profit is certainly in a position to go into the social life of its employee and to apply up-to-date methods in an effort to learn how to get results.

Whether this is being done or not it is not the purpose of this article to indicate, but the fact remains that men are leaving the mining districts to find work elsewhere.

In this connection it should not be forgotten that the falling off in mine employees began long before war was declared by Uncle Sam. As early as 1914 one of the larger coal companies advertised for 1000 coal miners for a single district.

It is not impossible that a solution may be arrived at on a scientific basis. The purchasing power of a dollar under all conditions has already been reduced to formula. The relation of labor to the rise and fall in prices of commodities and living conditions is also being tabulated, and as wages and capital are both involved, does it not seem possible that scientific light might illumine the pressing question of how to secure the much needed maximum coal production?

Legal Department

Alabama Prop Law—An Alabama miner who failed to designate the places where he desired selected props or timbers delivered by his employer is not entitled to recover damages for injuries on the ground that an accident to him directly resulted from the employer's failure to furnish props or timbers. (Alabama Supreme Court, Clark vs. Choctaw Mining Co., 78 Southern Reporter, 372.)

Liability Concerning Vehicles Carrying Passengers—One permitted by the general manager of a coal-mining company to ride gratuitously upon a hand car used in carrying express matter to the company's mine was legally a passenger as to whom the company owed the duty of using reasonable care for his safety, consistent with the mode of conveyance. Hence, such passenger is entitled to recover damages for injury resulting from a collision between the hand car and a train, due to negligence of the operator of the car. (West Virginia Supreme Court of Appeals, Hodge vs. Sycamore Coal Co., 95 Southeastern Reporter, 808.)

Co-Employees of a Mining Company Who Were Not "Fellow Servants"—Plaintiff, while employed by defendant mining company in assisting in shoving cars loaded with slate and other refuse from the mouth of a mine to a dump, was injured through negligence of another crew pushing another car over the same track. Held, that the members of the two crews were not "fellow servants" within the established rule in Kentucky that an employer is not liable for injury to an employee when caused by negligence of a fellow servant, with certain exceptions, as where it appears that the negligent employee had previously manifested such incompetence or carelessness as to charge the employer with negligence in retaining him in the service. (Kentucky Court of Appeals, Paradise vs. Elk Horn Mining Co., 203 Southwestern Reporter, 291.)

Negligence of Mine Superintendent—Pennsylvania Mine Foreman Law Construed—In affirming judgment for $9000 in favor of plaintiff for injury sustained through a fall of rock from the roof of a gangway into which he had stepped in defendant's mine, in which he was employed, to avoid an approaching car, it is held by the Pennsylvania Supreme Court that the recovery was sustained by a jury's finding of negligence on the part of the mine superintendent in failing to obviate the dangerous condition which had previously been drawn to his attention. It is also held that the Pennsylvania statute, providing for the appointment of mine foremen to have charge of anthracite coal mines, contemplates the placing of a foreman in charge of each separate mine; there is no compliance with the statute in placing in the charge of a single foreman several distinct mines, together constituting one colliery. (Kolalsky vs. Delaware & Hudson Co., 103 Atlantic Reporter, 721.)

Validity of Sole Selling Agency Contract—Corporate Management—Where a coal-selling corporation acts as the sole agent in selling all the coal produced by several mining companies, a contract of agency between it and one of such companies is not invalid as being in restraint of trade, if the selling corporation is not owned or controlled by the producing companies and sells the output of each mining company as its own product, and at such price as it will command in the market. A shareholder in a private corporation is not precluded from voting on a matter before a stockholders' meeting merely because he has a personal interest in that matter at variance with the company's interest. If a mining corporation has not issued its full authorized capital, it is discretionary with the directors to sell part or all of the unissued stock, subject to the right of each stockholder to buy his pro rata share of such stock. (West Virginia Supreme Court of Appeals, Thurmond vs. Paragon Colliery Co., 95 Southeastern Reporter, 816.)

Water Indicator and Motor Stop

By FRANK HUSKINSON
Lafayette, Colo.

SYNOPSIS — *On the mine water-supply system considerable trouble was experienced because the supply pump, which could not be watched all the time, would sometimes either pump the well dry or overflow the tank, or both. This difficulty was obviated by means of electric stops that operated just before the danger points were reached.*

THE water supply for domestic and power uses for a certain mine was stored in a large water tank upon the hillside, so that it would flow by gravity to the village hydrants, the boilers and other connections. This tank was fed from a well located in the valley of a creek, about half a mile away. A triplex pump driven by a 15-hp., three-phase induction motor was employed to pump water into the tank.

As most of the pumping was done at night by the watchman, there was no way for him to tell how much water was in the tank. Also at times the pump was forgotten and all the water pumped out of the well, allowing the pump to run on air. This is one of the worst things that can happen to a pump, as it soon cuts the packing and allows the valves to become loose and leaky, causing considerable trouble as well as expense.

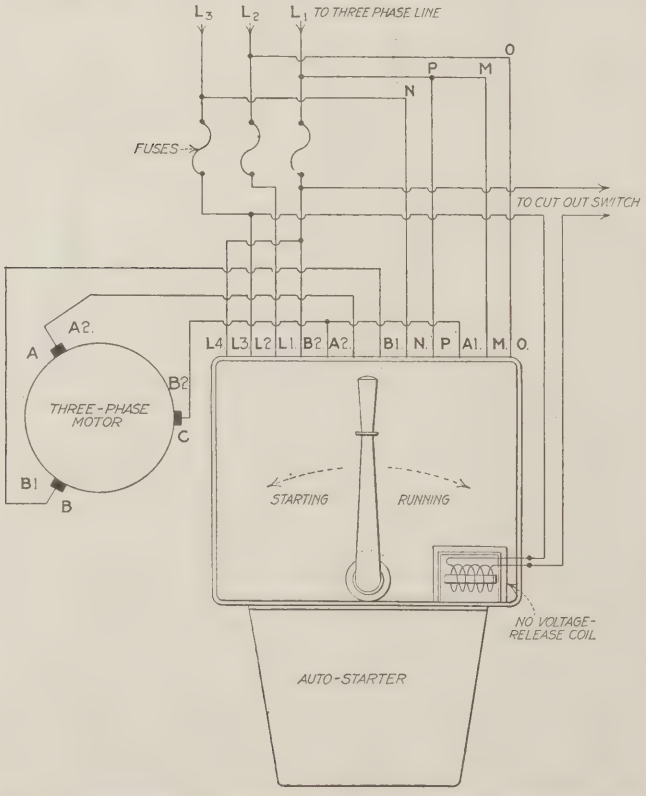


FIG. 1. ELECTRIC CONNECTIONS TO THE AUTO-STARTER

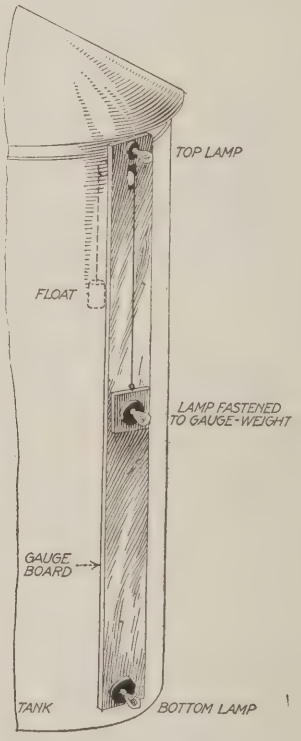
After a few cases of trouble of this character, and after the tank had been run over a few times, I decided that I would overcome this trouble by placing an automatic cutout on the motor, to be operated by the lowering of the water in the well and by the action of the gage on the tank when it was full. The cutout switch must stop the motor just before all the water was pumped out of the well, and it must also stop the motor just before the water in the tank would run over. While I was at it I decided to put in a set of visual signals on the water tank, so that anyone could tell at any time the amount of water in the tank.

In order to readily understand the principle and action of the automatic cutout arrangement on the motor operated by the cutout switches placed in the circuit, refer to Fig. 1. This shows the standard connections of a W-H auto starter, a type that can be used on several different kinds and styles of induction motors with good results; also it is a common type to be found around coal-mine installations.

The operation of the auto-starter is simple, and familiar. The lever is first pulled over as far as it will go on the starting side. As soon as the motor reaches full speed the handle is quickly moved from the starting to the running side (or position) where it is locked in place by the catch on the no-voltage-release coil. The action of this coil is to hold the auto-starter lever in the running position as long as current is flowing through the coil. Whenever this current is interrupted the coil loses its magnetism and releases the catch that holds the lever over on the running side. The lever instantly returns to the off, or neutral, position. It must be operated by hand in order to get motor started again.



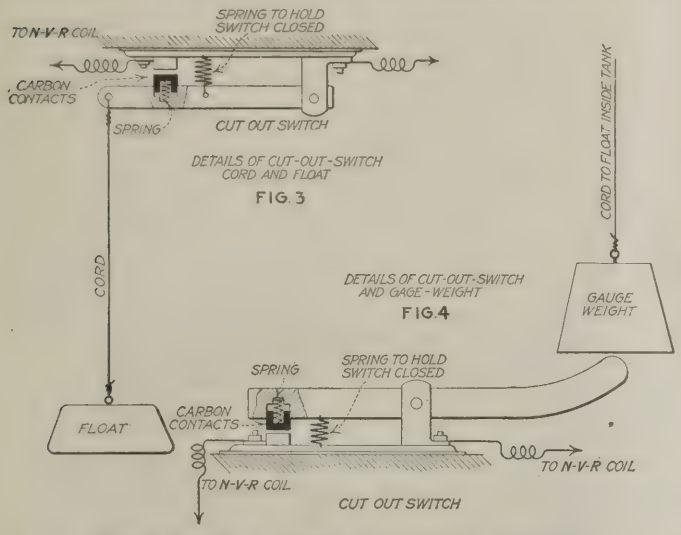


FIG. 2. ILLUMINATED TANG GAGE

In my arrangement to automatically shut off the motor whenever the water in the well was pumped down to a certain level, I arranged a special switch in series with this no-voltage-release coil. This switch had a strong cord fastened to the hinged portion, or blade, and on the other end of this cord was a large-sized float. This float was placed in the well and the length of cord was made such that just before the height of the water would allow the suction pipe to take air, the weight of the float would pull on the cord and cause the cutout switch to open the circuit in the no-voltage-release coil. This allowed the auto-starter lever to return to the off, or neutral, position, thus stopping the pump motor. As soon as the water rose in the well the cutout switch would automatically close. The circuit would thus be closed in the no-voltage-release coil, and the motor be in readiness to start again. Fig. 3 shows details of the float, cutout switch and connections.

In the arrangement to automatically shut off the pump motor, whenever the tank became full, a special cutout switch was placed on the gageboard of the tank and connected in series with the cutout switch and the no-voltage-release coil. The special cutout switch was placed at the bottom of the gage-board and arranged so that the gage-weight would come in contact with the handle of the cutout switch and cause it to open the contacts just before the tank was full of water, thereby opening the circuit in the no-voltage-release coil and allowing the auto-starter handle to automatically re-

FIGS. 3 AND 4. SUMP AND TANK CUTOUTS

turn to the off, or neutral, position and stopping the pump motor.

As soon as the water fell in the tank the gage-weight would leave the switch handle and the cutout switch would automatically return and make contacts again, thereby closing the circuit in the no-voltage-release coil. The pump motor would then be ready to operate again. Fig. 4 shows details of the tank, gage, cutout switch and connections.

This same arrangement can be applied to any protective device or apparatus that employs in its circuit a no-voltage-release coil (such as a switch or circuit breaker), the results being the same.

The visual signal to determine the amount of water in the tank from a distance was arranged by the use of three electric lights (see Fig. 2). One lamp was placed at the top of the gage-board, another at the bottom, while the third was fastened to the gage-weight with enough flexible cord to allow it to travel up and down the gage-board. With the three lights arranged in this manner it was an easy matter to gage the distance between the center or gage lamp and the other two, which distance indicated the amount of water in the tank.

With the motor protected by the automatic cutouts, the chances for trouble due to the pump running on air are eliminated. The visual signal is of great help to the pumper and the mine officials, as they can determine at any time the amount of water in the tank. With the tank protected from any liability of running over, quite an economy is effected in the saving of water and the unnecessary wastage of power due to the running of the pump motor.

With both tank and motor protection, the pumper can start the pump and leave it safely, with no fear of its running on air or the tank running over. It will be automatically shut off when all the water is pumped out of the well or when the tank is full.

A protective device of some kind should be put on all pump installations that are liable to exhaust their source of supply and run on air. The arrangements just described will work satisfactorily on almost any kind of an electric pump motor installation that utilizes an induction motor and an auto starter, or on any protective device that has a no-voltage-release coil embodied in its circuit.

Minecdotes

Mules Versus the Juice

The mine electrician and the pit boss were exchanging reminiscences of the past. The pit boss had just finished telling about his experience with a mule. "Mules," said the electrician, "always remind me of my first attempt to become a second Edison.

"It was this way: I had attained the advanced age of 13 and held the honorable position of trapper. Of course, at that time the height of my ambition was to become a mule skinner. This idea was fostered by the drivers, who were wont to help themselves liberally to my lunch and oil.

"One day we had a surprise. The company was going to put electricity in the mine. The use of electricity was not well known at that time around coal mines. I saw great prospects in the future and made a trip to town and bought a lot of electrical toys and books, with the result that in a short time I was much interested in the 'juice,' as the old timers called it.

"After many delays the big day came for using the 'juice' at the mine. The end of the trolley line was about 400 or 500 ft. from my door, and there were five lamps connected to the trolley line and rails. This made more light on the parting, it seemed to me, than if the sun had been shining there. Furthermore the electric locomotive was a seven-day wonder to most of us.

"A friend suggested that I could keep everyone away from my lunch and oil if I attached a wire to the trolley and onto my oil can and lunch pail, but that I would have to stand on a piece of dry wood myself whenever I touched them. I thought this would be fine, so I gathered up a lot of old bailing wire and proceeded to put in a line from my door up to the trolley line, working on it secretly and keeping it concealed so that no one knew what I was doing. I remember I had it under the rails and buried all over the parting. In some places it was fastened to the timbers.

"At last it was all in place, and I had my oil can and lunch pail sitting upon it at the door. I took a stick and laid the other end of the wire on the trolley line. I saw it make a big flash, but it stuck fast to the wire, so I went back to my door and awaited results.

"Well, results came quicker and in a much different way than I had expected. The first driver out had not much more than come through the door going onto the parting with his load when his mule seemed to

wake up all at once and started kicking and running. Every time that mule hit the rail there were sparks a-flying. The driver jumped off the car, stepped on the rail, and say, I sure thought he was crazy. He hollered, 'Oh, I am killed! I am killed!' He swore that the mule had kicked him all to pieces, and I am positive that the animal was at least 20 ft. from him and rapidly going further.

"Well, it was about the same with all of the mules. As soon as they would get through my door they would suddenly come to life and start to kicking and running. It made no difference what the driver said. They sure were a lively bunch, sparks flying from their shoes every time they hit the rail; and the drivers themselves seemed to have the same symptoms as the mules, only in some cases they were worse. I was enjoying myself hugely and wondering what caused all the excitement.

"Finally, the electrician was sent for. He was much puzzled for a while until he came to my door. There he stopped and filled his lamp with my oil. I was surprised to see him pick up the oil can, as I had it setting on a wire; but he had on a pair of gloves. Next he removed his gloves and reached over for my lunch pail. I don't really know whether he got hold of it or not. He acted worse than any of the mules, and the next thing I knew my enjoyment was cut short. The electrician had me by the ear and was telling me about a whole lot of things that were coming to me if I didn't show him where I had that wire fastened to the trolley line. I sure did show him. He cut it off and made me take up all of my line and said a lot of things to me about the 'juice,' etc.

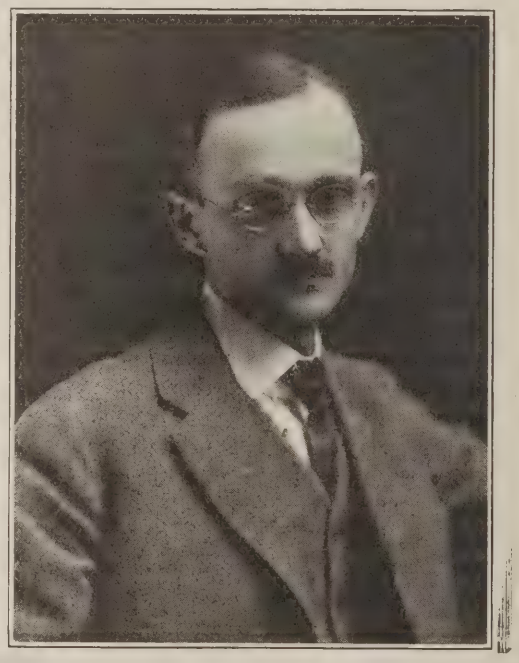
"After a while the mules became quieted down and the mine resumed normal operations. It was some time before the drivers and myself were on good terms again. That was my first attempt to become a second Edison, and I never see a mule or hear mule mentioned without vividly remembering it."

How Our Coal Output Is Consumed

The following table has been calculated from that given in Fuel Administration Order No. 553 and published in *Coal Age*, on June 15, 1918, Vol. XIII, page 1116:

ESTIMATE OF BITUMINOUS COAL USED IN 1917 AND TO BE USED IN THE COAL YEAR 1918-19

	In 1917	Per Cent.	In 1918-19	Per Cent.
Industrial	204,907,000	36.58	242,024,000	38.68
Domestic	66,915,000	11.95	75,678,000	12.10
Gas and electric utilities	33,038,000	5.90	37,941,000	6.06
Railroads	155,000,000	27.67	166,000,000	26.53
Exports	24,000,000	4.29	24,000,000	3.84
Beehive coke	52,450,000	9.37	52,450,000	8.38
Bunker—foreign	7,700,000	1.38	10,000,000	1.60
Bunker—domestic*	5,000,000	0.89	5,000,000	0.80
Used at coal mines for steam and heat	11,000,000	1.97	12,500,000	2.00
Total	560,010,000	100.00	625,594,000	100.00
Used from storage	4,375,000	0.079	.....	.....
Imports	907,000	0.17	.....	.....
Estimated production	554,728,000	99.04	.....	.....
Substitution of coal for oil mainly in west	.....	.....	2,000,000	0.32
To increase stocks†	.....	.....	7,000,000	1.12
Total requirements for 1918‡	.....	.....	634,594,000	101.44
Production 1917	554,728,000	99.04	.....	.....
Production 1918-19 required for needs	634,594,000	113.3a	.....	.....
Increase required	79,866,000	.....		



* Including Great Lakes. † For industrial plants and public utilities outside of New England, a ten days' supply. ‡No allowance for estimated conservation. *a* Production needed 1918-19 compared with use in 1917, not compared with production 1917.

Who's Who In Coal Mining

John Adrian Garcia

The late Marshall Field one time tabulated three things which one was to remember if he desired to achieve great things. These were the value of time, the success of perseverance, and the joy of originating. John A. Garcia, vice president and treasurer of the Allen & Garcia Co., engineers, of Chicago, Ill., evidently steadily kept before him this trio of principles as a guide, for hardly anything he has done since he received the degree of mining engineer from the Missouri School of Mines and Metallurgy in 1900 but could be traced to the conscious or unconscious application of the rules enumerated above.

Born in St. Louis, Mo., Aug. 26, 1876, Mr. Garcia early evidenced that he was willing to pay the price of

JOHN A. GARCIA

success in honest effort. No task at which he was put was looked upon as painful drudgery, to be reluctantly endured, but as an opportunity to be seized with joy.

After graduating from the School of Mines, Mr. Garcia spent several years in Arizona, Colorado, Arkansas, Missouri and the Middle West states in copper, lead and zinc mining, on railroad construction work, and as a chemist, etc. In 1903 he entered coal-mining work as mining engineer in the mining department of the Missouri Pacific R. R. He then became successively chief engineer of the Rock Island Coal Mining Co., Indian Territory; Consolidated Coal Co., St. Louis; Dering Coal Co., Burnwell Coal Co. and Consolidated Indiana Coal Co., Chicago.

Having made a study of his business, and knowing his profession in every detail, Mr. Garcia in 1911 formed with Andrew Allen, of Chicago, the Allen & Garcia Co., to handle the design, construction, development and operation of coal mines. The record this company has

throughout the United States speaks volumes for the success of the partnership, which has taken its place with the leaders in the development of the industry.

Mr. Garcia's specialty is to examine and report on coal mines and to direct the operation of properties. To assist in solving the problem of big tonnage, Allen & Garcia designed a cage to meet the most exacting conditions. This item of coal mining development is cited as it exemplifies the part Mr. Garcia is taking in making coal history. Quoting his words: "If we can help in any way to better the conditions of the industry, make mining safer, or improve our methods, it is not only our duty to do so, but our pleasure as well."

In spite of his devotion to his many duties, Mr. Garcia has still found time to contribute various articles on coal mining and kindred subjects to the trade and technical journals and mining societies. He takes a good grip on the joys of life and plays the game like a man. He is a member of the University Club of Chicago, the Engineers' Club of Chicago, and the Western Society of Engineers. He is married, and the father of two children—a boy of 14 and a girl of nine.

Novel Scheme for Boosting Production

OFFICIALS GAVE UP THEIR SUNDAY TO LOAD COAL AND SET AN EXAMPLE FOR GREATER PRODUCTION; PROCEEDS WENT TO THE RED CROSS

J. T. Morris, superintendent of the Stotesbury operation of the E. E. White Coal Co., operating at Glen White and Stotesbury, W. Va., employed a novel scheme of getting more coal out by using all of the officials at the plant on Aug. 4. It is true, of course, that Sunday should be observed, but, as he puts it, "Our boys in the trenches work on Sunday, so it won't hurt us." The autos were left in the garage that day and each man went after the coal with the true spirit of the citizen who wants to do his part.

The scheme was put up to C. R. Stahl, assistant to the general manager, and he was asked what he thought about it. His answer was characteristic of the man who can see things at a glance for their true worth. "Fine," he said; "I'll load five tons with you."

So there you have the scheme. Each official was to load five tons of coal in addition to his regular work, and on Sunday at that. Through the generosity of E. E. White, president and general manager, and the efforts of his loyal men, the proceeds go for the benefit of the American Red Cross and to help win the war, as the banner on the loaded car of coal in the illustration shows.

Those men who loaded five tons each were L. C. R. Stahl, assistant to the general manager; J. T. Morris, superintendent; E. T. Lilly, mine foreman; Tom Wattis, Bill Wattis, Edward Hylton, R. L. Spease, William Dover, assistant mine foremen; Charles Crews, chief electrician; J. K. Hodges, store manager; S. L. Deck, outside foreman; G. E. Rowe, warehouse clerk; James Hewitt, mining engineer; and Moscoe Duncan, timber foreman. Frank Thompson, motorman, and Claude Vaughan, brakeman, volunteered to haul the coal.

If every official in similar positions would each load five tons, the State of Virginia would have 300,000 tons to its credit from this source alone.

Reinforced-Concrete Pit Props

By M. Meredith
Liverpool, England

In consequence of the extreme shortage of pit timber, a considerable degree of interest attaches to a series of tests of reinforced-concrete props and beams which has been made in one of the engineering departments of the Manchester University. These concrete props and bars, which are made by the Lilleshall Co., Ltd., of Priors Lee Hall, Shropshire, England, are reinforced on the "Keedon" system, props up to 6 ft. long having three $\frac{3}{8}$-in. steel rods passing through corner hoops in triangular steel frames, fixed at intervals, and those 7½ ft. long having rods similarly placed through hoops in square frames. For beams the frames are oblong, with the four rod hoops arranged on the outside instead of on the inner, as in the case of the props.

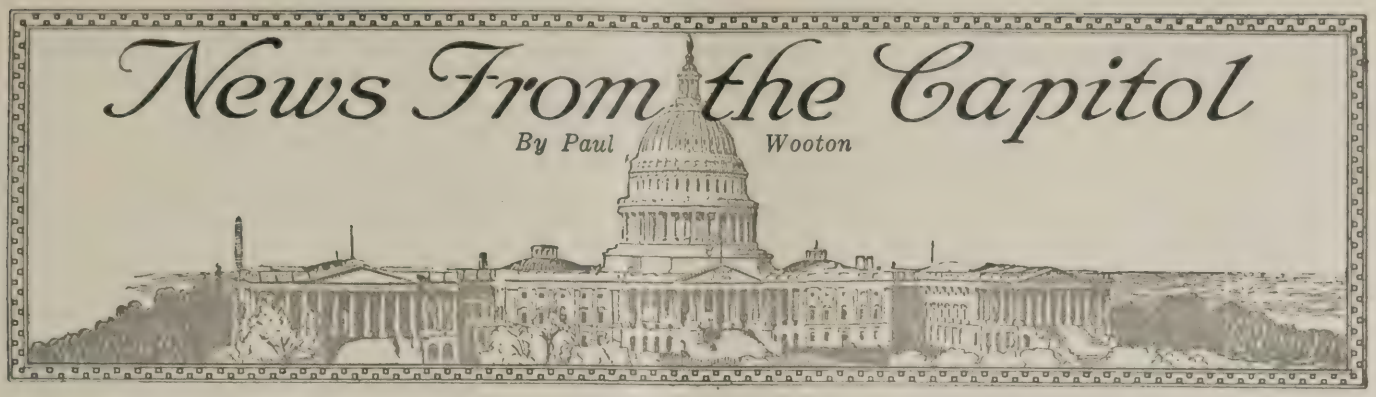
Three of the most interesting tests on the first day related to a 6-ft. concrete prop, made on the semi-dry system, reinforced with $\frac{7}{16}$-in. rods, but not containing Keedon hoops. This prop, which was six months old, was submitted to a pressure of 10 tons quickly, then increased at the rate of a ton a minute. At 30 tons the ends cracked, and at 34½ tons the prop fractured at the ends. It was then shortened to 5 ft. and again tested, breaking at 41½ tons. Again it was shortened, this time to 3 ft. 9 in., and fractured at 42½ tons.

A concrete prop 4 ft. 6 in. long and 4¾ x 4½ in., with $\frac{3}{8}$-in. rods, through Keedon hoops, made on the semi-dry system 12 weeks ago, crushed at the ends under a pressure of 26 tons, while a replica of this prop held 25 tons for 5 min. before breaking at one end. It was reset and broke at 12 tons, the ends of the rod curling round the concrete. The particular point of interest in these two series of tests was that the older the prop grew the firmer it became. In another test a 6-ft. concrete prop with rods and Keedon hoops caused a surprise by breaking at 19 tons. This was attributed by the makers to some fault in mixing and to the newness of the prop.

The timber customarily used in pits in pre-war days was Norwegian and Russian larch, and it seemed a pity not to have put some of this timber under test at the same time, so that comparative values might have been more precisely judged. Instead, a piece of pitch pine 4 ft. long and 6 in. in diameter was tested and broke at the ends at 37½ tons. The test was interesting but was of little or no value, as wood of that quality is not used for propping. Moreover, the clean-sawn ends were placed against the steel faces of the testing machine, whereas the concrete props had wood cushions at each end of 1⅛ in. thickness.

On the second day, however, some Welsh larch props —the timber that is being principally used just now— were introduced. A piece 5 ft. long and 5 in. in diameter was submitted to a pressure of 10 tons in 30 seconds, and then this stress was increased at the rate of four tons a minute. It broke at 25 tons, which gave 2800 lb. to the square inch. A piece 6 ft. long and 6 in. in diameter broke at 30¼ tons, or 2580 lb. to the square inch. One of the final tests was the trial of a 6 ft. 6 in. reinforced-concrete prop 7 in. in diameter as a bar, but when the load registered 22,800 lb. the bar was bending so much as to dangerously threaten to fail suddenly, and it was therefore withdrawn unbroken.

There were many other tests, but these seemed to be the most interesting. On the whole the views expressed by the experts present gave the impression that the demonstration was favorable to reinforced concrete. The fact that a prop could twice be cut down and reused, each time to greater advantage, furnished a reply to the objection made in some quarters that concrete props, unlike timber, could only be used once.



Then again, in no test did the concrete prop collapse by buckling or breaking in the center, as is usual with wood. Moreover, the prejudice entertained by miners to anything but timber, on the ground that props of the latter material "talk" to them—that is, that the creaking of timber just prior to a collapse affords them a warning to clear out of danger—should be removed by the fact that under the test pressure the concrete props also gave warning by a cracking sound and a crumbling at the ends.

Another thing that appears to favor concrete as against wood is that in deep mines, such as prevail in the Doncaster area, props of concrete may be safely left in a worked-out section, whereas timber must be removed as a precaution against fire. In this process as much as $25 and sometimes even $75 has been spent on the removal of a single piece of timber.

One point seems quite clear—namely, that concrete props and bars may be used to great advantage in main roadways, for while the initial cost is certainly greater than that of timber, in the pre-war era, the life is practically for all time, so that the ultimate cost shows a marked reduction.

To what extent general circumstances will permit of the use of concrete props at the coal face is another matter; but if they are advantageous for the roads any difficulties with regard to their use at the face should not be insuperable. Not only is timber scarce in these days, but steel scrap, such as rails and tube, suitable for cutting to pit sizes, is now almost unprocurable. Steel rails cut to lengths of from 6 ft. to 9 ft. have in the past been found extremely serviceable for propping near the face, interspersed with timber props. In such cases the longer pieces are bolted together, two thus making one support. The shorter lengths, however, are used singly. Eight-inch steel girders used as cross bars with timber props have stood in some of the main roadways for 15 years or more.

The difficulty now, however, lies in the inadequate supply of such material, and with plenty of concrete available reinforced-concrete props and bars look like a solution for an awkward problem. They are a "war" innovation, the first having been made in October, 1914. Arrangements are now being made to secure for them a permanent market. The makers, we understand, are now turning out about 3000 tons a week of the props, but how much greater the output will have to be, if the new system is favored by the mining authorities, may be judged from the fact that the normal consumption of pit timber in the collieries of Yorkshire, Derbyshire and Notts—which coalfields together yield 26 per cent. of the whole output of the United Kingdom—is 1000 tons a day. It may be of interest to add, however, that for every ton of timber used the three counties named produce an average of 170 tons of coal, compared with the low average of 33 tons of coal for every ton of timber used in the coalfields of South Wales.

Men Responsible for Greater Output

Production managers, on whose shoulders will rest the immediate responsibility of turning the curve of production upward, have been appointed by James B. Neale, of the Fuel Adminstration. The production managers and the fields over which they will exercise authority are:

Charles O'Neill, central Pennsylvania; F. B. Reiman, western Pennsylvania, north of Pittsburgh; R. W. Gardiner, Pittsburgh and Panhandle District; James S. Amend, Westmoreland, Irwin Gas, Ligonier, Latrobe and Greensburg; W. L. Byers, Connellsville region; Howard P. Brydon, Cumberland, Piedmont and Upper Potomac, Maryland, and West Virginia; F. M. Lockhart, Somerset-Myersdale; J. J. Roby, eastern and central Ohio; William H. Wallace, Michigan; James H. Pritchard, southern Ohio; H. F. Price, Big Sandy and Elkhorn; A. L. Allais, Hazard; J. W. Dawson, high-volatile fields of southern West Virginia; E. E. White, New River and Winding Gulf; R. D. Patterson, Tug River and Pocahontas field; G. D. Kilgore, Clinch Valley and southwestern Virginia; Howell J. Davis, Harlan field in Kentucky, Tennessee and Georgia; Judge H. C. Selheimer, Alabama; W. G. Duncan, western Kentucky; W. J. Freeman, Indiana; F. C. Honnold, Illinois; Ira Clemens, Iowa, Missouri, Kansas, Arkansas, Oklahoma and Texas; A. K. Craig, Montana and northern Wyoming; Thomas Sneddon, Utah and southern Wyoming; J. F. Welborn, Colorado; George T. Brown, New Mexico; Brooks Fleming, Fairmont-Clarksburg, and D. C. Botting, State of Washington.

Restrictions Lifted on Screenings

To meet the screenings situation, the Fuel Administration has lifted the restrictions on the use of that class of fuel by the manufacturers of clay products. This extensive industry will be permitted to buy screenings in unlimited quantities during the next 30 days. They will be permitted to store such screenings for use as they desire during the remainder of the year. This action was taken to relieve the accumulation of screenings in the Middle West.

Spreading Gospel of Conservation

A new force looking to the saving of coal is the recently created conservation section of the Railroad Administration. The section is under the management of Eugene McAuliffe. Just at this time, Mr. McAuliffe is sending out 500,000 extracts from the proceedings of the International Railway Fuel Association convention. Those portions of the proceedings which would be helpful to engineers and firemen were sent to all such employees of the railroads in the country. Likewise, other abstracts were made and sent to those most likely to profit by them. The abstract of the proceedings of the convention has been printed tastily, with the more important features brought out in black-face type.

Speakers to Boost Production

The production department of the Fuel Administration is increasing the number of its speakers to fifty. It is expected that one of the Administration's orators will be placed in each coal-mining district. In addition, a coöperative agreement has been effected which will permit of the use of the four-minute men on Labor Day and the Sunday preceding. Having noted the splendid effect of the "sings" among the soldiers, the production stimulators expect to encourage this practice among the mine workers.

To Take Prompt Action on Applications for New Coal Mines

Applications for permission to open new coal mines are to receive prompt action. A committee consisting of Frank G. Jones, chairman, S. M. Taylor and R. L. Ireland has been designated to pass on these applications for the Fuel Administration. The policy of the committee is to keep in view at all times the maintenance of the largest possible flow of marketable coal. Numerous applications now are pending. The committee assures that action one way or the other will be taken promptly on all of these requests.

Call Off Convention in Order to Work in Mines

An example of the practical results which are being obtained by James B. Neale, the director of production for the Fuel Administration, is the cancellation of the convention of the Russian Brotherhood Organization. A general assembly had been called for Sept. 16. Mr. Neale called the attention of the officials to the advisability of curtailing any gatherings which would necessitate the absence from work of a considerable number of miners. Jacob S. Koda, of Mt. Carmel, Penn., the supreme president of the organization, has advised Mr. Neale that he is in entire accord with the spirit of his request and that the convention has been indefinitely postponed.

Summary of Coal Loaded Since January

A summary of coal loaded since the beginning of the year has been issued by the Railroad Administration as follows:

	Decrease, Cars	Increase, Cars
Month of January	79,172	.....
February	.....	31,250
March	.....	46,613
April	.....	73,408
May	.....	84,998
June	.....	88,840
First four weeks of July	.....	113,188

Increase—1918 over 1917—359,125 Cars

The increased loading of coal, which is being effected, is shown by the returns for the week ending July 27, which follow:

	1918	1,917
Total cars bituminous	224,572	193,144
Total cars anthracite	40,942	43,050
Total cars lignite	3,657	2,813
Grand total cars all coal	269,173	239,007

To Conserve High-Grade Coal

Every effort is being made to cut down the demand on the high-grade coal of West Virginia, Pennsylvania and Maryland. Small as are the exports of this coal to the west coast of South America, steps are being taken to supplant even that demand. The Fuel Administration has arranged for the trying out in Chile of coal produced in the State of Washington. It is believed that this coal will be found to be adequate to the industrial needs of Chile, thereby relieving the eastern fields of that tonnage.

Coal Shipments Show Increase

An extract from the report of the regional director for the Alleghany region to the Director General of Railroads reads as follows: "In June anthracite coal loading was 63,187 cars, an increase of 4179 cars over last year; bituminous, 191,767, increase 22,781. July anthracite loading was 69,630 cars, an increase of 2329 cars; bituminous, 223,014 cars, increase, 35,100. Coal dumped at tidewater increased 223,537 tons in June, and 444,916 tons in July, as compared with corresponding months last year. Byproduct ovens are being operated at 94 per cent. of their capacity."

Laundries Not to Be Curtailed

No curtailment of fuel for laundries is to be made by the United States Fuel Administration. After a conference with representatives of the industry, it was decided that the matter of fuel supply for that industry could be handled best locally.

Detroit Assured of Adequate Coal Supply

Detroit has been assured an adequate supply of coal for domestic use. A delegation from Detroit visited Washington last week to emphasize the necessity of an early supply of coal sufficient to meet the needs of domestic consumers. The Fuel Administration declined to increase Detroit's allotment of anthracite, but will see to it that that city has a sufficient supply of domestic sizes of bituminous coal. The steam-coal situation in Detroit is described as excellent and it was not discussed at the conference.

New Lake Coal Handling Charges

Adjustments of charges for handling and forwarding lake coal have been made by the Fuel Administration as follows:

a. A lake forwarder may charge 20c. per ton on cargo coal for his services.

b. A lake forwarder may charge 25c. per ton for fuel coal furnished a vessel, and 50c. additional, or a total of 75c. per ton, where the coal is delivered to the vessel by barge or scow.

c. A purchasing agent may be employed by the lake forwarder to buy either cargo or fuel coal and charge a commission of 15c. per ton, if not prohibited by Rule 3 of Publication 22 from so doing.

d. A lake forwarder may pay a purchasing agent 15c. per ton for buying either cargo or fuel coal for him and add same to the 20c. allowed for cargo coal and the 25c. or 75c. allowed for fuel coal.

e. A licensed distributor acting as a lake forwarder or lake fueller who purchases coal from an entirely independent mine, or from a mine not owned or controlled by another lake forwarder or lake fueller, may add the purchasing agent's commission of 15c. per ton to the 20c. per ton allowed on cargo coal, and to the 25c. or 75c. allowed on fuel coal, but such sum cannot be added if the lake forwarder has employed an independent purchasing agent in the purchase of such coal.

f. No commissions whatever can be added by lake forwarders or lake fuellers to the applicable Government price of anthracite coal.

Brief Washington Notes

The Bethlehem Coal Co. reports that Charlie Mitchell, of Helens Run, near Fairmont, has mined 217 cars of coal in twelve days. At 82c. a car, his earnings for the period was $177.94, a daily average of $14.88.

A saving of 2,000,000 tons of coal a year is expected to result from the Fuel Administration's order making a reduction of 25 per cent. in the amount of fuel which may be used by the manufacturers of cement.

Hope of better transportation service for coal shipments is contained in the announcement of the Railroad Administration that to date 80 per cent. more grain has been handled than at the corresponding time of last year.

Five cents may be added to the mine price of coal delivered directly from mine tipples to locomotive tenders, or such other sum as may be agreed upon between the operator and the railroad receiving the coal, the Fuel Administration has ruled.

Equalization of storage was the subject of two conferences last week between Dr. Garfield, J. D. A. Morrow, C. E. Lesher, and other officials of the Fuel Administration, with J. J. Storrow, a delegation from New England and several state administrators. Prompt steps are expect to equalize storage.

The speed ship "Tuckahoe," which was built in the record breaking time of 37 calendar days, continues to make phenomenal time in the important coal carrying trade between Hampton Roads and New England. The "Tuckahoe" has set for other colliers in this trade a pace of four round trips a month. The average has been two round trips a month.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The labor situation looks quite critical at present, the practice of paying bonuses at the less responsible operations being the cause of the trouble. A mine with favorable conditions can afford to pay bonuses because the price of mining is set sufficiently high not to close those operations which are working under conditions not so favorable. So the well-circumstanced mines pay bonuses, and the men in adjoining mines wonder why it is not done at their mine where perhaps the conditions are just as favorable, but where the operator is willing only to pay the union wage and feels in fact a mandate from the government compels him to pay no more. Everybody has been opposed to bonuses—the Fuel Administration, the union and the old-time operators—but the practice has only in a few cases been strenuously combatted and the system has gone on. In fact it can be and probably is done more or less secretly and even disavowedly. On Aug. 16 Frank Hayes, the president of the United Mine Workers of America, announced that a meeting would be held today, Aug. 22, at which all the district presidents would be assembled. Mr. Hayes announces that the wage increase "can be met and applied by the coal operators without the necessity of an increase in the selling price of coal to the consuming public," and he adds that the payment of bonuses by many mine owners "is undisputable evidence that the industry is able to bear an advance in wages." All will agree that it is clear evidence that certain parties who are paying bonuses, and doubtless some others also, could stand an increase in wage scale without being deprived of their entire income. But to allege that this proves that all could stand the increase is untrue. In fact if the union wins out and prices remain fixed there will be a lot of concerns forced out of business, far more doubtless than the country could afford. Certainly, further readjustments of prices would have to be made.

> *We urge upon all concerned the absolute necessity of regular attendance at work and the need for working full time in accordance with the terms of our agreement so that every colliery in the anthracite field may be operated to a maximum of its capacity each day in the year as provided for in our agreement. To the end that the mine workers may be provided with all the equipment necessary for efficient operation, we urge upon all operators that they anticipate their needs well in advance, the difficulties of securing mine material at this time being abnormal because of the pressing requirements of other war industries. Where grievances arise and are taken up for settlement as provided for in our agreement, we urge company officials to be prompt and liberal in making adjustments to the end that unnecessary disputes may be avoided and unnecessary delays eliminated, and we pledge upon behalf of the board an earnest endeavor to make prompt adjudication of such disputes as do arise. We further urge upon operators and mine workers alike a united effort to make up for lack of numbers by added efficiency in work and operation.*—Anthracite Board of Conciliation.

It is regrettable that the steel business has seen fit to increase wages 10 per cent. just recently thus renewing its raid upon the coal industry, and cutting its own throat, for already the steel companies are complaining that they cannot get coal. A better plan by far would have been to keep the price steady and seek to increase the working force at the steel mills through the operations of the Department of Labor. The bidding for workers increases the industrial unrest. The mine worker is constantly leaving and returning and losing time, efficiency and the industrial habit in the process.

Mr. Hayes says speaking of the payment of bonuses:

"The practice has become so widespread that the stability of the entire industry is threatened and the coal operators themselves are becoming alarmed at their own handiwork.

"The Fuel Administration is conducting investigations to find out the reasons for the conditions and the identity of the operators who are bidding for labor by the payment of bonuses. Many of the operators' associations have petitioned the Fuel Administration to save them from the disastrous results of the bonus system.

"If bonuses are eliminated from the pay envelopes of the miners now receiving them the industry will lose thousands of men and it can ill afford to do so, for they are necessary if the production is to be even maintained at its present level and still more necessary if the nation's demand for a greatly increased output is to be satisfied.

"If the wages of those not now receiving bonuses are not increased by an equivalent of the bonuses now being received by other miners, then the industry faces a sure and certain loss of needed man power.

"For the protection of our entire war program, to keep the wheels of basic industry going full blast, it is necessary that a wage adjustment be made on a basis that will put an end to the wholesale competition for men and hold the miner to the mines where he would like to remain, if he is but given a wage equivalent to that which he would receive if employed in other industries."

In the anthracite region the matter of a new wage scale is no less urgently discussed, though bonuses do not exist. However, variations in wage scale from mine to mine are common. But these variations are not the real cause of the trouble, for the mine workers want larger increases than these variations represent. As stated last week, the miners in the northern district want an increase of 25 per cent. The brakemen and "motormen" of the Delaware, Lackawanna & Western R.R., Coal Department, are not satisfied with a raise of that character. They desire their rate lifted from 40c. per hour to 75c.

A few weeks ago some individuals made a request to Fuel Administrator Garfield for permission to reopen the wage scale. The answer was not favorable. Dr. Garfield refused to consider any increase in price outside of the seasonal increase provided and his decision made an increase in wage an impossibility. Recently he has received an application from the officials of the union. So far he has not replied, but it is unlikely that his reply, when received will be favorable. The mine workers contend that the recent awards to the railroad shopmen by the Railroad Administrator and to the street-car men by the War Labor Board give these men more pay than is received by many of the workers in the anthracite industry.

There is a degree of apprehension that some carefully veiled German propaganda are back of the trouble in the anthracite region. Only the most unprincipled person would be guilty of the declarations actually being made at meetings of union men to the effect that the operators are deliberately restricting production. It is almost unbelievable that men representative of the northern anthracite region would accept such sweeping charges and embody them in a resolution, but this they have just done. A charge that

an employer is disloyal is a well recognized weapon in the armory of the defeatist, as has been noted in Italy.

As evidence that the enemy aliens are still active, the fact may be even now stated that on Aug. 1 Alexander Frank, an Austrian, was arrested at the Wilson Creek mine, just north of Carbondale, one of the mines of the Delaware & Hudson Co. He was accused of having placed 65 sticks of dynamite in the Wilson mine with the purpose of wrecking it. The explosive was found hidden among props and was uncovered by men who were cleaning out a chamber. The prisoner refused to explain his action.

After All, Fight Is About Words, Not Facts

Seward Button, the chief of the Department of Mines of the State of Pennsylvania, it will be remembered, recently declared that the output of anthracite was cut down by drunkenness, idleness and the ease with which a sufficient wage could now be made. The miners want him removed. The general mine committee of subdistrict 4 of district 9 has passed resolutions condemning him and asking Governor Brumbaugh for his removal.

After several paragraphs reproaching Button and exculpating the mine workers, the committee concludes with the following acknowledgement of the facts which perhaps exactly expresses all that the wicked Seward Button tried feebly to make plain:

"Resolved further, that in passing these resolutions we are not unmindful of the fact that no industries with large bodies of employees can be absolutely free from isolated cases of men who neglect their work through drink or who are controlled by the hook worm."

All that Seward Button demands, all the industry demands, all that the nation demands is that the mine workers shall find these men and expose them so that all the world may know them. It is necessary that these men should be brought into line, and the mine workers are the people to bring them. We want the mine workers to "isolate" them still further. They should be made to feel as "isolated" as the "Man Without a Country." The mine workers should show plainly that these drunkards and "hook worm" sufferers are not accepted members of the mining fraternity, and the sober and industrious workmen should do it so plainly that the public would be under no misapprehension about the matter. The removal of Button will not do the work. The drunkard and the laggard must be removed.

Kennedy Is Suggested for Union President

An attempt is being made to groom Thomas Kennedy of the Hazleton district for the presidency in place of Frank B. Hayes who is now filling John P. White's unexpired term. The anthracite mine workers want recognition in the union, the office having gone too frequently, they believe, to the bituminous regions. Kennedy has not made up his mind whether to run or refrain. He says that he will decide definitely before Oct. 1.

The United States Fuel Administration has requested the Roman Catholic priests to eliminate weekday services, which are used by the foreign population as an excuse for absence from work, which absence is often prolonged.

The suggestion has not been received everywhere with favor, though the priests almost universally are heartily in favor of doing all within reason to increase the production of coal. One priest, the Rev. M. A. Lambing, pastor of St. John's Roman Catholic church at Scottdale, made a public statement objecting to the request and said that instead of seeking to stop the weekday religious services the administration should turn its attention to the liquor problem. For every bushel of coal lost through attendance at church, he claims, there are tons lost through insobriety. He charges that the request of the Fuel Administration is in effect putting a tax on Catholic piety.

The strike which occurred Aug. 3 at the Dodge colliery of the Delaware, Lackawanna & Western R.R. Coal Department came to an early end. It involved, however, over 1000 men. The company makes the statement that the cause of the strike was the demand made by six miners who had been working in the Dunmore No. 1 vein that they be given a higher rate than the scale called for. They were told that they could accept the rate or leave, and quite unexpectedly a strike was declared.

The G. B. Markle Co.'s day men are seeking changes in the wage scale. The engineers of that company are striking for an 8-hour day. They will not come to their work till 7 a.m. Heretofore they would get the engines ready so that the men could be in the mine by that time.

A holy day occurred last week, Aug. 15, the Feast of the Assumption, and that with the great heat had a deterrent effect on production. The Lehigh region did not shut down for that feast day; the miners worked as usual. The Lehigh Coal and Navigation Co.'s collieries in the Panther Creek valley operate on all church holidays and they do not have as much irregular work as elsewhere. The men can be brought to time for irregular attendance as they do not have the broad opportunity to wander from mine to mine afforded them in the northern region where the mines are operated by a number of different companies.

Hot Weather Drives Surface Workers Home

The outside workers in the recent "hot spell" complained so much of the heat that an early closing of the collieries was necessary and the electric storms at places made a further closing down obligatory as they put the electrical machinery out of commission. The East Point Coal Co. at Pond Creek was laid idle by the storm of Aug. 12.

The recruiting trouble is now less acute than in the past. It is beginning to be understood that we must not call miners if we do not want them to enter the army. If they are to be suffered to remain at work, it must be clearly understood that they are not wanted in the national service. Once they are called, they will insist on serving, feeling that a failure to serve will subject them to criticism.

Some of the mine workers in West Virginia are making remarkable records, among them Charlie Mitchell, an American miner of Helen's Run, Worthington, W. Va., a mine owned by the Watsons of Fairmont, operating as the Bethlehem Coal Co. Office records show that during the last 12 working days in July Mitchell loaded a total of 217 cars at 82c. a car and that he made a daily average of $14.83 or a total for the 12 days of $177.94. This is believed to be the record for northern West Virginia.

The coal operators of western Kentucky are enforcing the "work or fight" law. Under the enactment of the session of 1918 every man from 17 to 60 years of age must work at least 36 hours a week. At two mines in Hopkins County 37 miners were recently arrested for failure to work, the arrests being made as they left the mines. Of these 35 were employees of the Victoria mine and two of the Grapevine Coal Co. Ffteen of the men were fined $20 and a day's work on the roads, and the others were dismissed. The men had been working at most two days a week.

Miners Must Work Whenever Occasion Offers

Slow work has been the order of the day at these mines; last year the companies could get few cars and in years previous few orders. The opportunities to work in western Kentucky and in Kentucky generally are none too good even now. In the week ending July 27 the car shortage was 17.3 per cent. and on Aug. 3 12.4 per cent. But the people of Kentucky are bound that Kentuckians shall work whenever they have the opportunity.

The fuel administration in Michigan has given the mine workers almost all their demands. They have conceded to them the 10 per cent. increase in passenger rates, forbidding the operators to charge it to their miners. It has given them the increase in wage of 10c. per ton, but it will take effect Aug. 16 instead of from last fall.

In Arkansas, 400 miners employed at the Central Coal and Coke Co.'s plant No. 6 went on strike Aug. 14. A trifling dispute as to who should sprag the cars at the bottom is said to have been the cause of the strike. Superintendent W. H. Risper says the men refused to sprag the cars and that two trips of 12 cars each were permitted to run into the dump of the mine. The men alleged that the

pit rules exempt them from the work of spragging the mine cars. About three months ago Tom Wimberly, a miner, lost a finger trying to sprag cars and he charges that when he asked for compensation the company refused to pay him, presumably because he was not employed for that purpose. Following this action, the miners gave the company three days' notice that they would not sprag the cars. The notice expired Aug. 14 but the system was not changed. A short time ago the company's employees at its No. 3 mine refused to go to work because the tipple was unsafe. A new one is being built and will be completed about the latter part of this week.

In Nanaimo, British Columbia, a draft-evader by the name of Goodwin was killed in making his arrest and certain labor leaders sought to make capital out of the matter. The funeral was largely attended and trouble was feared between the military police and mine workers. It was at one time declared that if the police were not withdrawn and if draft-evaders were not given immunity a strike of all the coal miners on Vancouver Island would be ordered. But better counsels prevailed and there has been no trouble.

It appears as if the miners of the United States will persist in the celebration of Labor Day, Sept. 2, despite the need for coal. The miners declare they wish to demonstrate to the public on that day the importance of the mine workers' services. It appears that the downward trend of the curve of production for the 5 weeks following the week after the Fourth of July in 1917 will be repeated this year. It has been so far as recorded. The Feast of the Assumption, the hot weather and the poor car service will doubtless show in the coming report of the Geological Survey. Sept. 2 was comparatively harmless last year, but it seems likely that this year it will reduce tonnage considerably.

Garfield Pleads for More Anthracite

Dr. H. A. Garfield addressed the following letter to the Board of Conciliation in the anthracite region:

"Our country is in the midst of a dreadful war across the sea and is facing a very serious situation at home. The war abroad cannot be won and the situation at home cannot be successfully met without a marked increase in the production of coal.

"Much more coal is needed if General Pershing's army in France is to receive from the great army of mine workers at home the complete support which it so richly deserves. Coal is the bed rock on which our industrial system rests, and without an adequate supply, our war program of ships, food, clothing and arms and ammunition must drag. The papers each day bring word from France of the splendid achievements gained by bravery and sacrifice on the part of our overseas army. Surely our army of mine workers and operators at home will see to it that equally cheering news of our achievements goes to France. We are justly proud of our soldiers and must give them good cause to be justly proud of us.

"Much more coal is needed if hardship and suffering in many homes in this country is to be avoided during the coming winter. Surely our army of mine workers and operators will see to it that this situation is successfully met.

"For an increase in the anthracite tonnage I turn to you, knowing the splendid results which you gentlemen, as the Board of Conciliation, have obtained during the past fifteen years and knowing that you represent the two effective elements necessary to increased production, namely, operators and mine workers. The operators must strive for higher efficiency and for uniformly good physical conditions in their collieries. The mine workers must report for work each day and must not only stay in the mine the hours prescribed by the wage agreement, but must also see to it that there is a marked increase in the tonnage.

"In the anthracite wage agreement, dated May 5, 1916, under which you are now working, there is the following clause:

"'An 8-hour day means hours of actual work for all classes of labor, at the usual working place, exclusive of noon time, for six days per week, if the operator desires to work his mines to that extent, excepting only legal holidays. The time required in going to and coming from the place of employment in or above the mine shall not include any part of the day's labor. Drivers shall take their mules from the stables to the usual working place before starting time and shall return them to the stables after quitting time, compensation for such service being included in the day rates established for this class of labor. If, because of breakdowns, repairs, or the requirements of transportation, or other causes essential to efficient operation, it is found necessary to extend the normal workday of any employee, or any class of employees, the operator may do so, at his option, paying for overtime a proportional rate per hour as determined from the rates established under Section 1 hereof.'

"Under date of Apr. 26, 1917, in a joint conference of anthracite operators and miners, the following resolution was unanimously adopted:

"'Be it resolved by the coal operators and mine workers, represented in the Anthracite Joint Conference, that we hereby instruct the Conciliation Board to offer its services to the Council of National Defense and to render such assistance to the council in maintaining the production of coal and in enlisting the maximum coöperation of employers and employees represented in the anthracite coal-mining industry, so as to meet the requirements and needs of the Government as set forth by the Council of National Defense; and also to provide for public necessities.'

"The offer of assistance expressed in the resolution has been accepted by the Council of National Defense. It is therefore with a feeling of full confidence that I look to the anthracite industry to meet the needs of the nation in this crisis. This will require the very best effort of every one from the highest official to the smallest breaker boy and I know that it will be cheerfully given. The plans to be followed to make every man and boy connected with the industry realize the gravity of the crisis and his own individual responsibility in it, I shall leave entirely to you, saying only that there must be no doubt in the minds of the operators and mine workers but that the anthracite tonnage must be largely increased. Here is a splendid opportunity for the highest patriotic service. You and your fellow workers will make the best of it, I'm sure."

The Board of Conciliation promptly wrote a letter addressed to the anthracite operators and mine workers, saying:

"To the end that the efforts of the United States Fuel Administration may be successful, we solicit the utmost measure of your whole-hearted patriotic coöperation toward adequately meeting this great public emergency. We recognize that the best efforts of operators are now handicapped by the abnormal difficulty in securing necessary machinery and material for operation. We also recognize that the ranks of the mine workers are depleted, but we believe that greater production can be secured in spite of these difficulties if the program of united effort herein suggested is generously supported by mine workers and operators alike, working together in full coöperation and sympathy to the common end of winning the war and supporting with the last pound of enrgy your neighbors, friends, relatives and fellow workmen now at the front in France in the National service."

The latter part of the letter is displayed in the center of the first part of this department. The letter was signed by W. L. Connell, S. D. Warriner, W. J. Richards, John T. Dempsey, Thomas Kennedy and James Matthews, comprising the full board.

Miners Want Commutation Service

The mine workers at Herrin, Ill., who work in the Williamson and Franklin County field lying to the north of that village, are complaining that "miners' trains" are not provided to take them to their work. They purpose forming a committee to deal directly at Washington with William G. McAdoo, Director of Railroads, and they have requested Congressman E. E. Dennison to head that committee.

The mines near the town of Herrin have, they claim, the better supply of mine workers while the newer and more efficient mines, where a greater tonnage per man can be produced, being farther away, can hardly get any men at all. The mine workers point out that every day in the southern Illinois fields miners' trains leave Sparta, Duquoin, Christopher, Harrisburg and Marion, and every night bring the miners back. They think they are even better entitled to this service at Herrin, for the mines surrounding Herrin produce more coal than the mines surrounding any one of the cities mentioned.

EDITORIALS

The Miner as a Casual Worker

A LITTLE thought will convince us that the miner is not like other men. Somehow he has the casual habit, that habit which we rightly regard as typical of the Middle Ages. No longer are there 300 working days in his year; in fact there are far from that number. Even when the mines are working irregularly the days on which they do work do not find a full force engaged. The miner is a casual worker with the industrial habit only partly developed.

The casual character of the miner's life arises from two causes—the irregularity of the opportunity for labor and the fact that mining labor has always been recruited from that industry which is most casual and seasonal, an industry, in fact, which we shall see later has hardened its casual character in some countries by something approaching ordinance.

It is needless to speak regarding the opportunity offered for steady work. Everyone who knows the industry is aware that the mines, in normal years, only work about 200 days. There is hope, however, for steadier work in the future. The industrial use of coal is likely to grow larger per capita, whereas the domestic use of it per capita is likely to be more or less steady. We shall never ask for more than a comfortable heat, for anything above that heat is undesirable.

Houses are now being built so as to economize what heat is supplied. The leaky old frame houses of the past let in an immense quantity of cold air and did not keep out the cold because the walls were too thin to prevent the conduction of heat. While the number of rooms to be heated per capita is an uncertain quantity, it does not seem likely to increase with time. True, the workingman is demanding more rooms, the rich man is building himself a spacious house, but at the same time the tendency of the middle class in the big cities is toward small apartments and toward more aggregate living with consequent saving in heat.

Moreover, byproduct coke, which is more and more used as a domestic fuel, can be stored and therefore its use will help to spread the production of coal over the year. The water powers also, which need supplementing with coal during the summer and are well supplied by the streams in the winter, serve to act as a balance wheel to the industry.

So much for the future. What about the present? The domestic requirements of bituminous coal are only 12 per cent. of the whole bituminous production, according to Dr. Garfield's summary, which we print on another page. The Geological Survey in 1915 put it at 16 per cent., coupling with it the small steam trade. As already indicated it is the domestic trade which is markedly seasonal.

However, it is true there are other uses that are seasonal. In the winter more gas is consumed and the railroads use more fuel, and possibly head winds at sea may cause a greater use of bunker coal. The mines use more coal both for power and heat. (This latter item is credited separately in Dr. Garfield's account.) But on the whole the seasonal character of the trade even in normal years applies only to about 15 per cent. of the product, for a part of the domestic business is for summer consumption though not much is used in that season. Thus, all things considered, the seasonal character of the coal trade is not so great as might be thought. A trifling change in methods might make the bituminous industry run evenly the year round. No account has been taken of the anthracite industry, for that is already more or less satisfactorily stabilized by the regulation in price.

The other important cause for the casual work of the bituminous coal miner arises from his past associations. The mining industry has been recruited in this country largely from native and foreign farmers, and farming is one of the most seasonal of industries. In consequence the farmer is quite apt to be casual in his labor.

So much is this true of the farmer that most of the great feast days which are so faithfully celebrated by the foreign population occur in the winter. The summer is relatively free of celebration probably because such days as were instituted for that period died a natural death, lacking public support. The inception of many of these feasts dates back several centuries before the Christian era; others are not so old, but are related to those which have an earlier existence. They are mostly placed in that part of the year when people engaged in agriculture found celebration did not interf re with attention to their physical needs. At present they tend to come just when our industrial life ordinarily demands the greatest amount of activity and when the demand for coal gives the operator the intensest anxiety.

But it is not necessary that these feasts should thus interfere with production. Foreigners coming to this country and engaging in other occupations than mining do not keep them to anything like the same extent as the mining population. The verdict is, "You must work on these days or move out," and they work. They soon get the industrial habit of working whenever the chance offers.

In many years the mines have more men than they want. When this occurs the operator does not care much whether his men work or are idle. When, later, men get scarce those who have been secured have to be nursed. The operator is like the man with a leaky roof. When the weather was fine, repairs of the roof were not necessary; when it rained, it was impossible to repair it. It was therefore never repaired. Similarly, in the mines there is never any serious attempt to correct the casual habit. The operator feels it would be unjust as well as uncalled for to do it so long as his operation works so casually, and, when the mine runs steadily he is afraid that to correct the failing would cause him to lose men, for output is dearer to him than discipline.

Some cure should be found. It is probable that it will be worth all that it costs in the satisfactory opulence that the miner will enjoy when he works every day, and in the certainty that he will feel if he knows every day that the man on whose services he relies to help him get out his tonnage will not be on a spree and leave him in the lurch.

Drivers of Yesterday and Today

A WHILE ago a good friend of this publication, and a man with wide knowledge of mining, wrote a letter of criticism from which a few words might be culled as a text for a further dissertation on the proposition to which his objection was taken. He says:

"Some time ago I saw an article in *Coal Age* in which you predicted that the day was not very distant when all employees in coal mines would be paid by the day, and contract work abandoned altogether. I was surprised to see this from you, for you certainly know about coal mining and the class of men who are following it, and you know that unless they are paid by the piece they will do nothing at all. The driver today does not give within 10 per cent. of what he did five years ago in return for the money he receives, neither does the trackman, timberman or, in fact, any other dayman; and I regret exceedingly to say that some of our present-day mining bosses are not much better."

In all of this statement there may be a degree of truth, if the writer means to say that the driver—let us give that functionary our whole attention—does not put himself as whole-heartedly into his work as he did in the years past. If his dictum is that the driver is not making as much of a study of his task, and is not early and late hustling at it as he used to be in the past, we shall not try to reply to that statement. The matter is at least debatable, and so little is it a matter of statistics that we are little disposed to debate it.

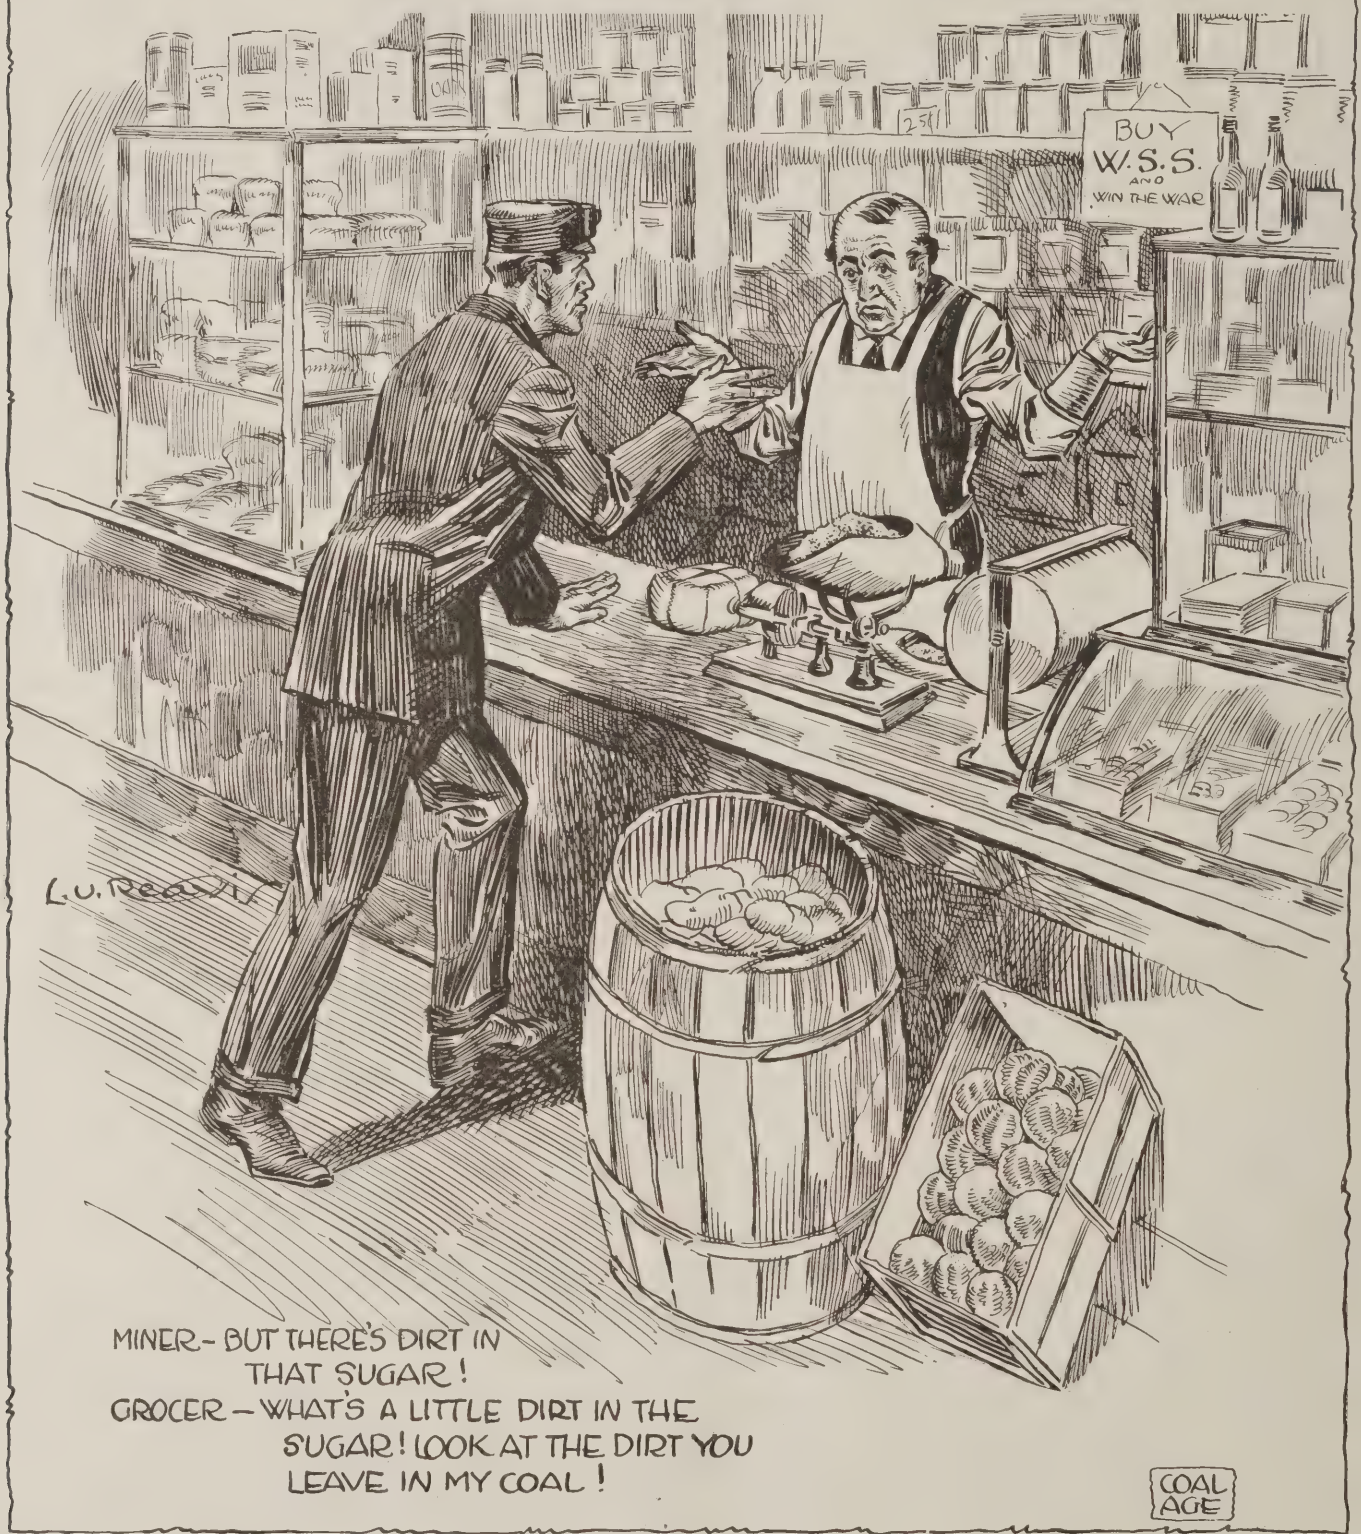
The giants of the days that are gone perhaps were not such giants after all—but perhaps they were. We shall not attempt to consider the question. We do know, however, that the industry in general agrees unanimously that the driver of 1918 is not willing to do as good a day's work as the driver of 1915. The war and the shortage of help have wrought a marvelous change in him in those three short years.

But the assertion we tried to make was not that the driver and his like were trying to do as much work or were working as hard as ever, but that they were actually *achieving more.* Formerly the driver hauled 2 or 3 one-ton cars on a level; now with his hand on the controller of the locomotive he pulls 25 two-ton cars. Formerly he drove his mule at three to six miles an hour, now he "lazies along" at 10 miles.

Formerly he waited long at partings, now as there are few "motormen" on a run he goes along merrily most of the time. It being as easy to sit on a moving locomotive as on one standing still, he has no tendency to keep his controller handle at "off." We do not say he is morally better; we say he is so aided in his work by mechanical appliances that he does not do 10 per cent. less but from 1000 to 3000 per cent. more.

Where he still walks along with his hand on a mule's hip and a whip coiled over the kerchief on his neck, we have shortened his journey by moving the locomotive parting so that without excessive work he is handling a large tonnage. He no longer has to go clear to daylight or half that distance with every trip he gathers. Efficiency has been thrust upon him, whether he will or no. Efficiency is always sure sooner or later to be thrust on the dayman. We cannot afford to leave him to his native inefficiency. On the whole he does not care much so long as his wage is secure.

The contract miner, of course, has had some help given him. When mines were not unionized or when the unions where weak, machines were introduced and a scale profitable to miner and operator introduced. But now the union is adamant. There must be no more mechanical changes unless the miner gets the whole benefit. In fact the union has been trying to readjust matters so as to deprive the machine operator of his whole advantage. The union wants the operator to shoulder the risk and expense, to supply the power and give his men the benefit. As a result we read about this and that new type of machine for lightening labor, but few are interested. You have to prove not only that it lightens labor, but that the union will permit that lessening of labor to show a lessening in the cost per ton.



The various elements in the cost of handling coal *after* it is mined have gone up but little. The cost of mining has steadily gone up. We are getting less and less for our money, and the condition will never be cured till day-labor replaces piece labor. Then the efficiency of changes made in mining methods will be placed squarely up to the operator, and the gains made by successful variation of those methods will go to him. There will be an income in the providing of facilities for operation; there will be a reward for inventiveness; supervision will not be an expense, but a source of income; the mine will become a factory. We shall not spread our forces over a whole township. We shall bring them together and give them the many mechanical devices they need.

Suppose the coke drawers had formed a powerful union and had secured a scale for drawing which would not permit of variation. Where would the various mechanical devices for coke drawing have gone? To the scrap heap. Fortunately, it was found possible to pay for coke drawing by machine at a lower scale or more generally by the day. Immediately the ovens were made of a different shape, the coke pusher made its appearance and the coke loader followed.

There is a big future for the man who will rearrange his mines so as to make close supervision possible, who will so place his forces that the men can work without delays and who will then by mechanical aids make the performance of the work easy. But the reward will only come to him if he operates his mine with day labor and secures for himself the profit of the methodical plans put in operation. On the other hand, if, having given of his best and having expended his money, he is to find the cost of digging and loading coal is as heavy as ever, the cost of power, supervision, repairs, ventilation, drainage and every other item increased, where will be his reward except as he can get it from larger output provided per unit of tipple force?

Mere hustling will never result in effectual progress. We can speed up the workman till his muscles refuse further service but only machine operation will really save the situation and there will be few machines introduced unless the operator profits by introducing them.

Sauce for Goose Is Sauce for Gander

You don't want to buy a poor article, neither do other people. Give the public good clean coal. They are entitled to it. They don't expect to get roof-slate, bone and sulphur when they pay for clean coal.

DISCUSSION BY READERS

Scraper Mining in Low Seams

Letter No. 1—Kindly allow me to draw attention to what appears to be a serious misstatement of facts in regard to the originator of the scheme for utilizing a scraper for conveying the coal from the face of a chamber to the gangway, in the working of a seam of low coal.

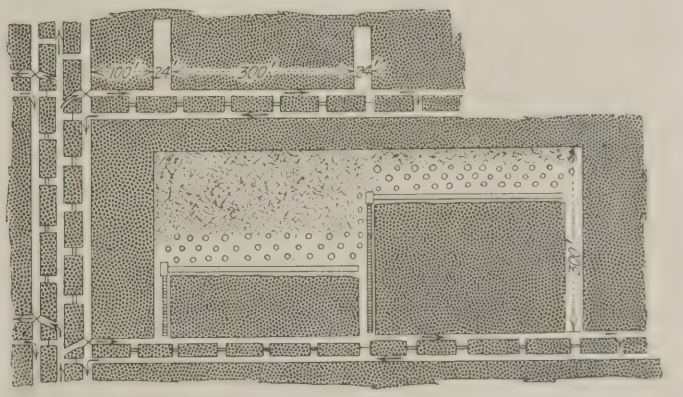
In the "Annual Equipment Issue" of *Coal Age*, July 20, p. 92, appears an article written by H. G. Davis, in which he mentions what he is pleased to call "a simple face conveyor." After describing the device and its application to practice in mines of the Delaware & Hudson Co., working a 38-in. seam of anthracite, Mr. Davis states that Cadwallader Evans, Jr., now with the International Salt Co., in northern New York, "was the first to introduce this system in the coal mines," and adds, "I am under the impression that he has patented some parts of the equipment."

While Mr. Davis gives no dates, in this connection, permit me to draw attention to the fact that, to the best of my knowledge, this matter was first brought to the attention of the coal industry in the anthracite region, in an article that was published in the Employees' Magazine of the Lehigh Valley Coal Co., April 1916, pp. 67-69, where it is stated that the scraper was tried out about two years previous, Jan. 15, 1914, at the Seneca Colliery of the company.

WHERE THE FIRST SCRAPER WAS BUILT AND USED

The article goes on to say that the scraper was built in the Seneca Colliery blacksmith shop and had been in constant use up to that time, a double-drum electric haulage engine being employed to pull the scraper back and forth, in place of mule power. The writer of the article mentions further that the scraper was then being successfully used in the following four collieries of the Lackawanna Division: Seneca, Maltby, Stevens and Exeter. This article was reprinted, at the time, in the issue of *Coal Age*, June 17, 1916, p. 1044.

If I am correctly informed, the Mr. Evans to whom I have referred did not enter the employ of the Delaware & Hudson Co., where Mr. Davis states the scraper has now been introduced, until the latter part of 1915, coming there from Nova Scotia. It is worthy of note that one of the employees of the Lehigh Valley Coal Co., who was acquainted with the experiments that had been conducted at the Seneca Colliery of that company, and who had sketches of the system there employed, left the Lehigh Valley Company and started to work for the Delaware & Hudson Co., shortly after Mr. Evans became one of the officials of that company.



It would seem an injustice to the coal-mining industry that Mr. Evans should take any steps, if such is the fact, to patent this device that has been in use so long a time in anthracite mines. While it cannot be claimed that the scheme is perfect, it is far superior to any other method that has yet been tried. I can state with certainty that those who first developed the idea had no thought of monopolizing it by applying for a United States patent, their whole purpose being to make more profitable the mining of low coal in the anthracite mines.

JOHN LLOYD, Efficiency Engineer,
Wilkes-Barre, Penn. The Lehigh Valley Coal Co.

Coal Conveyors at the Face

Letter No. 2—Having had considerable experience with the Blackett conveyor, when mining coal on the longwall advancing plan, the letter of "Mining Engineer," *Coal Age*, July 20, p. 142, drawing attention to the great advantage of the face conveyor in mining coal under favorable conditions, interested me.

The face conveyor is particularly adapted to the mining of thin coal; and, believing that its use in this connection will be of interest, I beg to present a plan that I have found can be quite generally applied to

PROPOSED ARRANGEMENT OF CONVEYOR FACES

the working of thin seams of coal and makes possible a good percentage of extraction at a reduced cost of operation.

The plan presents the following advantages that are well worthy of consideration: (1) The work is concentrated in a small area, which bears a marked contrast to any form of room-and-pillar working where the men are much scattered. (2) The work is all retreating and the loss of much coal thereby avoided. (3) A greater degree of safety is secured than where pillar work is necessary. (4) A less length of track and fewer cars are required.

OUTLINE OF METHOD OF WORKING THIN COAL

Briefly described, the plan of working is as follows: As shown in the accompanying figure, cross-entries or levels are driven to the right and left of the main haulage road and air-courses, at distances of 350 ft. apart. The main entries are driven three abreast on the full pitch of the seam, the center entry being the

main haulage road and intake air-course, while the two side entries are the main return airways.

The two return airways are flanked by pillars of coal 100 or 150 ft. in thickness, depending on the roof pressure and the character of the overlying and underlying strata. Beyond this pillar, as shown in the figure, rooms are turned to the rise at distances of 300 ft. apart, and driven up a distance of 100 yd., where they are connected by driving a heading across the face. A 50-ft. pillar of solid coal separates the faces of these rooms from the next pair of cross-entries.

When all is ready, a conveyor is installed at the face. Bottom is lifted in the room so as to permit the conveyor to load the coal directly into the cars standing on the track at the head of the room. About 15 men can work on a single face 300 ft. long, which gives each man 20 ft. of coal to load. This arrangement makes possible a large output of coal at a reduced cost of operation. As shown in the figure, two or three rows of posts are kept standing back of the conveyor. The posts are set at regular distances apart and staggered. As the work advances, the conveyor is moved forward and the timbers in the rear row are then drawn and stood nearer the face.

General Form of the Blackett Conveyor

The general form of construction of the Blackett conveyor is well enough known not to need further description than to say that it is of the type known as "scraper conveyors." The troughs are made in lengths of 6 ft. and are flexible enough to allow of considerable bending, which permits the line of the conveyor to be moved forward 5 ft. in 20 yd. The troughs are 10 in. in height and 19 in. wide on top. The endless chain that operates the scrapers passes over a return drum, which rests on a sliding carriage that permits the tension of the chain to be increased when necessary. I have found the Sylvester post-drawing chain of great assistance in moving the drum forward.

In one mine, in England, the installing of a face conveyor increased the output from 4 tons to 10 tons per man, while the labor required was much less, eight men and two boys taking the place of 18 men and 18 boys under the old system.

A conveyor known as the Mickly conveyor, which was used to a limited extent, consisted of a low car attached to a rope passing around a sheave at each end of the face. This car was hauled to and fro along the face and traveled on rails that extended over the top of the mine car standing on the track at the roadhead. The contents of this truck conveyor was dumped into the mine car through doors in its bottom.

Oak Hill, W. Va. William Dickinson.

Mining Equipment

Letter No. 7—Many interesting and instructive articles have appeared in *Coal Age*, from time to time, under the caption "Mining Equipment." The letter signed "Patriot," July 20, p. 140, proved particularly interesting to me. Like the writer of that letter, I find it hard to understand why the average coal-mining executive seldom makes public his views and opinions when they would be of such great benefit to the industry.

I heartly endorse the statement made in the letter to which I have just referred that "the columns of *Coal Age* perform a powerful function." Let me add further, that the views presented in these columns reach a far greater number of interested people than when spoken at an institute meeting or other assembly.

In his letter "Patriot" attributes the lack of coöperation and understanding between many men of the coal-mining fraternity, to business policy, professional jealousy, or a failure to see the advantages to be gained by proper intercourse on matters relating to the operations in their charge. I am convinced however, that a more probable cause is carelessness or, at times, press of business. Allow me to second what has already been said by this writer, and urge compliance with his suggestion that coal-mining executives acquaint us, through the columns of *Coal Age*, with the results they have obtained from the labor, equipment and methods employed.

Officials Generally Willing To Impart Information When Asked

It has been my experience that executives of coal companies seldom refuse and are generally glad to supply information concerning the performance of equipment they have installed, whenever this information is asked. I have observed the same willingness to impart information when these executives have been present at institute meetings and other places where such matters were being discussed. This strengthens my conclusion that their failure to offer these facts and figures, for publication in the coal-mining press, does not arise from unwillingness on their part to give the information desired. It is more the result of thoughtlessness or lack of time.

Let me say, in closing, that at the present time many thousands of dollars' worth of equipment is being purchased by various coal-mining companies, for improving their facilities for producing, transporting and preparing coal for the market. This makes it all the more urgent that every coal-mining executive should charge himself with the duty of informing his fellow workers of results that will be of benefit to all.

Pittsburgh, Penn. Worker.

Ventilating a Gassy Slope Mine

Letter No. 2—Mining men will differ, no doubt, in respect to many details regarding the ventilation of a gassy mine, but the information asked by "Mine Foreman," *Coal Age*, July 25, p. 191, as to the best system of ventilating a slope mine, driven in a seam dipping 6 per cent. and generating large quantities of gas, should bring out many good practical ideas.

My theory regarding the ventilation of such a mine coincides, almost precisely, with that described by the editor, in his reply to this inquiry. It is my opinion that such a mine should not be opened by less than three main slopes driven on the full dip of the seam. These slopes should have a cross-section not less than 6 x 10 ft. above the roadbed and, as stated, the center entry should be the intake and main haulage road, while the two side entries are the return air-courses.

In my opinion, it would be well to turn off the first pair of levels to the right and left of the main road, at a distance of 100 or 125 yd. from the mouth of the mine,

instead of 150 yd., as suggested by the editor. My idea is that a shorter distance would give less trouble in the handling of the gas generated in this seam. The three slopes should all be driven at the same time, in order to get the best results in the ventilation of the mine and enable the crosscuts to be driven at proper intervals.

As has been stated, the first-right and first-left levels should be intakes and haulage roads, while the second-right and -left levels are the return airways. This arrangement will afford the best haulage facilities for the rooms driven to the rise of the levels. An overcast must be built at the mouth of each of the first-right and -left entries, so as to conduct the main return air over the haulage road on these levels.

For the ventilation of the mine, I would install two 7-ft. centrifugal fans, placing one of these at the mouth of each return airway and operating one continuously, while the other is held in reserve for use in emergency. By this system, no difficulty should be anticipated in securing the proper ventilation of the mine. The condition is such that the colder intake air will tend to fall readily, following the dip of the seam; but, after its temperature has risen, owing to the absorption of the natural heat of the mine, the return air will follow the rise of the seam, in passing out of the mine. This will have the practical effect of making the entire circulation in the mine ascensional, and less power will be required to maintain the circulation. I shall watch the further discussion of this subject with interest.

OSCAR JONES,
Gas Inspector.

Worley, Ky.

Letter No. 3—"Mine Foreman," of Tower Hill, Va., *Coal Age*, July 25, p. 191, asks a very fair and timely question, hoping to gain what information is available in respect to the best method of ventilating a slope mine in a gassy seam pitching 6 per cent. He is wise in seeking this information before starting to spend money in the development of such a proposition.

There are many questions that one would naturally consider when opening a mine, aside from that of ventilation. These relate to haulage, drainage, economy of mining the coal and operation of the mine, including the installation of pipe lines and conductors, for supplying power and light in the workings, and suitable means of ingress and egress that would insure the greatest degree of safety.

Regarding ventilation, my plan would be to drive five headings on the dip of the seam. Two of these would be used as intake airways and haulage roads, while the remaining three headings would serve as return airways. The location of these main slopes is important. They should be central to the bulk of the coal to be mined.

At the first favorable opportunity, when the slopes have been driven a suitable distance, I would start three branch headings, say to the right, and a short distance further down the slope three branch headings to the left. It would be my purpose not to drive these right and left branch headings opposite to each other, believing thus to afford greater strength in the roof formation and provide better facilities for laying the switches and making other haulage arrangements.

Assuming favorable conditions, the present improved methods of machine mining will yield as good coal in the headings as can be obtained in rooms. For this reason, unless the demand for coal was urgent, I would probably start no rooms until the headings had been driven, say 800 ft. This plan would give ample means for a large production of coal when needed. My preference would be to limit the length of the branch headings to say, 1200 ft.

For the ventilation of the mine, two large fans should be installed, in the most suitable place, at or near the mouths of the three return airways. These fans should be of the reversible type to permit of reversing the air current should this be needed.

R. W. LIGHTBURN.

Perryopolis, Penn.

Sealing Off Fire on Intake

Letter No. 11—Kindly permit me to offer my plan of sealing off the fire, described by "Ancora," *Coal Age*, June 22, p. 1173, as having gained such headway on the intake of a pair of blind headings that it has been decided to seal off the entries.

To avoid tedious repetition, I will pass over the suggestions of the several correspondents in regard to approaching the fire with caution, employing two crews to relieve each other, and short-circuiting a portion of the air current by opening the nearest stopping outby from the fire. Further, I would slow down the ventilator slightly, or otherwise reduce the volume of air passing in these headings, believing that 30,000 cu.ft. per min. is more air than is needed at present under prevailing conditions. My opinion is that sufficient air should be permitted to pass over the fire to carry off the smoke and gases while the first stopping is being built on the intake.

SUGGESTS CLOSING THE INTAKE FIRST

My plan is to build the intake stopping first, leaving an opening in it 2 x 2 ft., which is to be closed later, by a trapdoor, when the return stopping is in place. Then, before starting to build the return stopping, I would speed up the fan and increase the circulation, in these entries, to 50,000 cu.ft. per min., if possible. Next, erect a brattice on the return airway so as to deflect this current toward the place where the stopping is to be built. This would have the effect of driving back the gases generated by the fire. Both the intake and return stoppings should be built just inby from the crosscut opened, or about 18 yd. outby from the fire.

My theory is that, under this arrangement, sufficient air will be supplied to the fire to produce carbon dioxide, which will have an extinctive effect and prevent the formation of an explosive mixture. A 2-in. pipe should be built into both the intake and the return stoppings, about a foot from the roof. Near the bottom of the return stopping, I would also place a 3-in. pipe with a valve, and another 2-in. pipe about half way between the two, as that might be found useful in case it was decided to employ water in extinguishing the fire. Having completed and sealed the return stopping, I would immediately close the trapdoor in the intake stopping, and leave the fire to die out for want of air.

My plan contemplates the possibility of being compelled to drown out the fire by the use of water. For

that purpose, I would build good substantial stoppings and make these water-tight. It is not stated in the inquiry whether the headings are running to the rise or to the dip or are level, and these conditions may modify the method slightly, in case it becomes necessary to use water to extinguish the fire.

If the headings are running to the rise and making some water, this will naturally drain from the face toward the fire, while if the headings run to the dip, it will be necessary to pump a considerable quantity of water through the pipes built into the stoppings. The same is true, but a less quantity will be required, if the headings are level. JOHN L. WHITE.

Portage, Penn.

Letter No. 12—When this discussion was first started I decided to wait and watch its development, as I knew many practical ideas would be advanced. Before giving my own views, formed by a long practical experience in the fighting of many mine fires, permit me to comment briefly on some of the statements that have been made.

The discussion was opened by W. H. Noone, *Coal Age*, July 6, p. 33. After naming as the three dangers encountered in mine fires, the following: (1) the formation of an explosive mixture; (2) the generation of poisonous gases when the air supply is limited; and (3) the ill-effects of these gases on the workmen, Mr. Noone suggests the building of the first stopping on the intake, after short-circuiting the air current by opening the stopping next outby from the fire. He then proceeds to direct this air current up the return airway and through the last crosscut, extending it from that point inby to the face of each heading.

VALUABLE TIME LOST IN BUILDING BRATTICES

In all my experience in fighting fires in mines, I have never known or heard of this method being employed. In my opinion, valuable time would be lost in building this line of brattice, if indeed it would be possible or safe to attempt. Let me suggest, also, that both the intake and return stoppings should be as close as possible to the opened crosscut, in order to supply fresh air to the workmen.

In his letter, July 13, p. 79, Oscar Jones makes some good suggestions, but let me say that any fire that would permit of the building of both stoppings at the same time, as he proposes, is a fire that could be extinguished in another way and avoid the necessity of building the stoppings. Another interesting letter is presented by R. W. Lightburn, July 20, p. 143. His plan of carrying the stoppings to a height of 4 or 5 ft., before attempting to complete either of them, is a good one, but he omits to mention the need of inserting a pipe in the stopping, which is always important, and, like Mr. Jones, he suggests building both stoppings at the same time.

On the same page, another correspondent, Thomas Jones, starts his letter well, but I fail to see the advantage of sealing the return airway first, as he advocates. By so doing he would subject the workmen to the heat, smoke and poisonous gases, coming from the fire. In my opinion, this could hardly be done, except at a great distance out on the entry; but that would be a bad plan. Again, his proposal to "wait a short time to allow the space behind this stopping to fill with the smoke and gases generated by the fire," is of doubtful value; because there will be some circulation of air, which will flow into the space along the floor of the entry still open and discharge at the roof. This will operate to dilute the gases Mr. Jones hopes will shortly fill the space back of the stopping.

PROPOSED METHOD OF PROCEDURE

In describing my own method or plan, let me say that this is a fire that has passed the first stages of development when it might have been handled in the ordinary way, and must now be sealed off so as to enable other districts of the mine to be worked with safety while waiting for the fire to gradually die out.

Assuming that all necessary material and tools have been collected quickly and that a few cool-headed men, organized under an experienced leader, have reached the place, the first step is to open the nearest possible stopping outby from the fire so as to short-circuit the air at that point. Then, start to cut out the floor and rib, on the intake, as close to the fire as practicable, and set in place 8 x 10-in. square timbers to enable a double-plank partition or stopping to be constructed and the 10-in. space between the planking filled with clay. This stopping should be sealed and made air-tight at once, so that no fresh air can reach the fire.

Having completed the intake stopping, work on the return must be started immediately. The men must be worked in relays, using only safety lamps. First, a curtain is hung on a frame, a short distance inby from the opened crosscut. Follow this immediately with a light 1-in. board brattice, the men holding their heads low while performing the work, so as to avoid, as far as possible, the smoke and gases traveling at the roof.

The light brattice just erected will keep back much of the smoke and gases from the men, while the heavy double-plank stopping is being put in next. This is constructed in the same manner as that built on the intake, except that a 2- or 3-in. pipe 6 ft. long must be built in this stopping and provided with a valve. It is important to permit no one to enter the return airway while the work of sealing off the fire is being performed, except the men engaged in building the stoppings, and they must be aided, in every way possible, by directing the fresh air current so as to reach them.

CONDITION OF AIR BEHIND STOPPINGS

Regarding the two questions relating to the condition of the air behind the stoppings, it may be said that the conditions would be much the same whether the first stopping were built on the intake or on the return. The air behind the stopping would be unfit to breathe and, perhaps, explosive owing to the presence of carbon monoxide. Having never sealed the return airway first, I can give no opinion based on that method. Tests taken after both airways are sealed show that the air behind the stopping is generally non-explosive, but will kill a mouse in less than five minutes when exposed to the flow from the mouth of the pipe.

In closing, allow me to say that, in the handling of 23 fires, by sealing them off with air-tight stoppings, none of the workmen have become unconscious or been injured in any way. In one or more instances there have been as much as 40 tons of coal burned, but the fire has been extinguished without delaying the work.

Worley, Ky. GAS INSPECTOR.

INQUIRIES OF GENERAL INTEREST

Exhaust of Gasoline Locomotives

We have had some discussion, regarding the danger of the exhaust from a four-cylinder gasoline locomotive when used in a mine. I would like to ask how much air will it take to render harmless the exhaust from this locomotive, assuming that the four cylinders are each 4 x 5 in. and the engine is run at a speed at 1500 r.p.m.

Also, kindly state to what extent carbon monoxide (CO) is soluble in water.

————, Tenn. MOTORMAN.

To give an answer to this question based on the volume of burnt gases exhausted from the four cylinders of this engine when running at the given speed would be misleading and of no practical value, in respect to the danger arising from the poisonous gases that are liable to form a considerable proportion of the volume of the exhaust.

It is well known that extremely small percentages of carbon monoxide are highly poisonous and may often prove fatal when breathed for any length of time. On the other hand, it is practically impossible to name the percentage of this gas, in the exhaust of a gasoline locomotive, that would represent even average conditions in mining practice. Some have estimated that, when a gasoline engine is running normally, under favorable conditions, the exhaust from the cylinders contains about 1 per cent of carbon monoxide.

In the series of tests made by the engineers of the Federal Bureau of Mines, and described and tabulated in Bulletin 74, published by the Bureau, it was found that the percentage of carbon monoxide, in the exhaust of this type of engine, varied from a fraction of 1 per cent. to 15½ per cent. This wide variation, it was stated, is dependent on the rate of fuel consumption as determined by the adjustment of the carburetor, speed of engine, proportion of load, and temperature, as determined by the efficiency of the water jacket. These tests showed that the maximum production of carbon monoxide occurred in the exhaust when the engine was running at full speed, under full load, requiring a high rate of fuel consumption.

Very much will depend on the intelligence and skill of the motorman and his ability to adjust the carburetor to the speed and load under which he is running. The percentage of carbon monoxide increases with the temperature of the mixture; and, on this account, it is of the utmost importance to maintain a cool water jacket.

As is well known, the usual construction of the engine is such that each cylinder gives one explosion during each alternate revolution of the shaft. A four-cylinder engine would thus give two explosions per revolution of the engine, or 3000 explosions per minute when running at a speed of 1500 r.p.m. The piston displacement of one 4 x 5-in. cylinder is $4(0.7854 \times 5^2) = 78.54$ cu.in. in a single stroke.

A calculation based on 3000 explosions per minute in this engine, gives, therefore, for the volume of exhaust gases $(78.54 \times 3000) \div 1728 = 136+$ cu.ft. per min. Assuming the worst condition shown in the tests of the Bureau of Mines, where the exhaust gases were found to contain 15.5 per cent. carbon monoxide, would give $136 \times 0.155 = 21+$ cu.ft. carbon monoxide gas.

One-tenth of 1 per cent of this gas in the mine air would be extremely dangerous where the men are forced to breathe such air continuously. A degree of safety can only be assumed to be attained when the percentage of this gas is reduced to 0.01 per cent. To secure this condition, on the assumed basis, would require $21 \div 0.0001 = 210{,}000$ cu.ft. of air in circulation.

Assuming a normal velocity of 600 ft. per min., this circulation would require a sectional area of 350 sq.ft. It must be remembered, however, that we have assumed the worst condition that could arise, as determined by the tests of the Federal Bureau of Mines, although it cannot be denied that such a condition is possible when running the engine under full load, at full speed, especially when the water jacket is not working to the best advantage. Even under favorable conditions, an inexperienced motorman, through an unfortunate combination of circumstances, may develop as bad or even a worse condition than that we have mentioned.

The great danger, in the use of a gasoline locomotive in a poorly ventilated mine or airway, arises when a motorman allows his engine to continue running while he is waiting for a trip. The danger is much increased if the ventilation is temporarily slackened or completely cut off owing to the setting open of a door. An ample circulation of air is always important on the haulage road where a gasoline locomotive is employed. The utmost caution is required also, on the part of a motorman when pulling a heavy trip up a grade and moving with the air current. In such a case, the motorman may be enveloped in the gases exhausted from his engine and be overcome before he is aware of the danger.

On the other hand, the most improved types of locomotive possess advantages that particularly adapt them to the conditions existing at certain mines where there is a long-distance haul from the mouth of the mine to the tipple; or where the main haulage road is of ample size and haulage is performed on the intake air, provided the length of haul, inside of the mine, is not too great.

Attention has often been called in *Coal Age* to the fact that much of the trouble experienced in the operation of gasoline locomotives arises from the employment of incompetent motormen who fail to understand the proper adjustment of the carbureter to the load the motor must carry. It is this lack of adjustment that causes most of the trouble. One of the chief advantages of this type of motor, where conditions will permit of its use, is the economy in its operation.

Carbon monoxide is only slightly soluble in water; 100 vol. of water will dissolve 3 vol. of the gas.

EXAMINATION QUESTIONS

Mine Foremen's Examination, Pittsburg, Kan., May 15, 1918

(Selected Questions)

Ques.—What precautions would you adopt to prevent the accumulation of firedamp on top of falls where it is difficult to remove the gas with the air current?

Ans.—Trouble from gas on falls is mostly met in pillar workings where every effort must be made to prevent its accumulation, by erecting a special form of brattice with canvas so arranged as to deflect the air current to the top of the falls. When the falls are high it is frequently difficult to remove the gas from its lodging place.

Where the condition is particularly dangerous because of the accumulation of large quantities of gas on falls in abandoned places, and it is not practicable to seal off such places completely, the precaution should be taken of sinking drill holes from the surface to tap the gas and drain it from the mines. In any event, the volume of air should be increased as much as possible and the current directed so as to sweep the falls.

Ques.—What are the causes of falls of roof, and how would you make an inspection to determine the security of a roof in a mine?

Ans.—The extraction of the coal in a seam leaves the roof without support at that place, and the character of the roof may be such that it will tend to fall in the opening, unless it is properly secured by timbers. Falls of roof are caused by driving too large openings or carrying too small pillars, which yield under the great weight above them and cause the roof to break in the opening. The lack of systematic timbering or the use of a system that it not adapted to the condition will often induce a squeeze and cause heavy roof falls. Falls of roof are also caused by the presence of gas or water in the roof strata, whereby an undue pressure is exerted on the roof where it spans an opening.

In order to determine when a roof is secure, a careful examination should be made to detect the presence of any slips or fault lines in the strata. The roof should be sounded with a pick, while holding the other hand against the slate or rock to detect the effect of the blow. The manner of placing the timbers and the condition of the posts should be carefully observed and their effect studied. A careful watch should be kept for the first evidence of a squeeze, which would seriously affect the security of the roof.

Ques.—The pressure producing ventilation being 20.8 lb. per sq.ft., what is the water-gage reading?

Ans.—The water gage corresponding to a pressure of 20.8 lb. per sq.ft. is $20.8 \div 5.2 = 4$ in.

Ques.—What conditions would guide you in determining the width of headings and rooms?

Ans.—The conditions that must be studied, in determining the width of headings and rooms, in coal mining, are the following: Thickness and character of the overlying strata; thickness and inclination of the seam and the hardness of the coal; the character of the roof and floor of the seam; the presence of gas or water in the strata; and, finally, the method of working and system of mining employed.

Ques.—How many cubic yards in a room 65 ft. long, 14 ft. wide and 3 ft. high?

Ans.—The cubic contents of this room is $65 \times 14 \times 3 = 2730$ cu.ft.; or $2730 \div 27 = 101.1$ cu.yd.

Ques.—What conditions would a low or lowering barometer indicate in a mine? Explain fully.

Ans.—The existence of a low barometer, assuming this is stationary, may be taken as a fair indication that the atmospheric pressure will shortly increase. When the barometer continues falling, however, the atmospheric pressure grows steadily less and less, and this should be taken as a warning of a possible increase in a gaseous condition, in a mine having large abandoned areas that are more or less filled with gas or in workings where the nature of the roof is such that gas accumulates above the draw-slate or other roof formation.

A decrease of atmospheric pressure is always followed by the expansion of gas, which is thus forced out onto the roads and travelingways in the mines. The decrease of atmospheric pressure, indicated by a falling barometer, however, does not have the effect to materially increase the emission of gas from the pores of the strata in which it is confined, as is often supposed. The forces tending to hold the gas occluded in the strata are far more powerful than the slight change in pressure caused by any ordinary fall in the barometer.

Ques.—The rubbing surface of a square airway is 150,000 sq.ft.; the length of the airway is 4000 ft.; what is the perimeter?

Ans.—The perimeter of this airway is $150{,}000 \div 4000 = 37.5$ ft. The airway being square, the length of each side is $37.5 \div 4 = 9.375$ ft., or 9 ft. $4\frac{1}{2}$ in.

Ques.—How should a fan be located with reference to the top of the air shaft? Which do you prefer, direct-connected or belt driven? Give reasons.

Ans.—A ventilating fan should never be located directly over the fan shaft, but should be set back a short distance so as to protect it from injury in case of an explosion occurring in the mine. There should also be provided explosion doors above the shaft, which will relieve the pressure should an explosion occur.

A belt-driven connection is generally preferred to direct connection, for the reason that the former gives a greater flexibility, insures a more uniform operation of the fan and a less strain on its members, arising from any sudden change in pressure due to some unexpected occurrence in the mine. A belt connection permits of a gradual absorption of the shock that would otherwise be imparted to the fan shaft and its bearings, besides allowing change of speed by using a smaller or a larger pulley.

COAL AND COKE NEWS

Harrisburg, Penn.

Soft-coal production in the central Pennsylvania district is about all that could be expected. According to the statement of the operators, the mines are getting all the cars they can use and the effects are being seen in tonnage shipped. Better car supply is the largest factor in this increase, though the per capita output of the miners has also incrased.

Richard W. Gardiner, manager of bituminous coal production in the Pittsburgh district, states that he has no fear of a coal shortage for domestic consumers and essential industries in his field, provided the railroads furnish the necessary cars.

Discussing the matter, Mr. Gardiner said in part: "With the amount of tonnage which will be released at the close of the Lake season, and with the district representative having the authority to order this coal shipped where it is needed, it does not seem possible that the conditions of last winter will be repeated. A number of consumers of coal are of the opinion that the docks at the head of the lakes are receiving too much consideration, but people who think this are losing sight of the seriousness of this lake situation. The only way of getting coal to the great Northwest is by water transportation over the lakes, and when the lakes freeze the movement is stopped."

Mr. Gardiner said that because of the demands of the Lake region and the steel and other essential industries, Canadian shipments of bituminous coal from this district are being curtailed greatly. He said this condition of affairs is likely to exist for some time and that, because of this shortage of cars, shipments to concerns on the preference list may also be considerably curtailed until the lake shipment has been completed, which will be about Oct. 1.

The Anthracite Consumers' League, through Representative Frank C. Reese, will ask the Government to investigate the cost of production of coal. Reese is confident that an investigation will show that the cost does not warrant the high prices. He said: "We would like to know whether there has been included in the cost of coal the money paid for the rental and fixed charges of the Schuylkill Canal, which was taken over by the coal trust and allied railroad companies to avoid its competition in the carrying of coal, and which has since been allowed virtually to go to ruin. The high price now charged for anthracite acts as a depression on industry and business, and the Government should thoroughly inform itself as to the basis of these charges."

Charleston, W. Va.

If it should transpire that less coal is produced in West Virginia during August than was the case during July, it will be due solely to a statewide shortage of cars in August—a condition of affairs now regarded as an anomaly, since for the most part in the last few months operators have accepted the car supply as a matter of fact. Complaints as to a bad supply come from all parts of the state. Last Saturday the supply dwindled away to 440 cars in the Fairmont district—only about one-fourth of the normal supply. This shortage seems to have been caused by congestion at many points, according to admission of railroad officials, who claim they will have the matter straightened out in the next four or five days.

It is given as the opinion of operators that it is useless to make an effort to increase the production of coal if the continued shortage of cars is permitted to exist. It is hoped, however, that the present week may see the end of the unfavorable conditions.

Mines in the New River field have recovered to some extent from the power shortage of last week, which for a few days put a dent in production figures. This week the operations are forging ahead and are making some progress toward increasing the output over previous months. The New River district is one of the few districts of the state which has not suffered in the last few days from a poor car supply, and even that district has felt it to a limited extent.

While the Pocahontas and Tug River districts made a fine showing during July, production during the early part of August dropped, with a dull thud, 43,920 tons. Much work seems to have been lost through celebrations of speeding departing selected men for military service since the number of hours worked shows a decrease.

The Fairmont District has been literally "shot to pieces" for the last week. There were not enough cars on hand one day last week to supply railroad fuel orders, and it was feared that there were several railroads which might have to confiscate coal in order to keep their engines going; 440 cars was the sum total on the region—approximately one-fourth of the supply. The number of cars in the region had not fallen as low as that since about the middle of April. However, the supply was much better at the beginning of the week, there being 1931 cars on hand in this region last Monday; the mines supplied by the Monongah division of the Baltimore & Ohio as a result operated to full capacity. On the other hand, the mines on the Monongahela railroad have no cars at all as the result of several cloudbursts. Congestion in the East on the Baltimore & Ohio has been cleaned up, and steps are being taken to prevent a recurrence of such congestion. Restrictions were placed on shipments to the east and as a result there was a large movement to the lakes. The region is still laboring under the pressure to supply coal to Curtis Bay under Government orders.

Some idea of how seriously crippled the mines of the Kanawha District were last week may be obtained from the fact that production was only 168,030 tons—a drop of about 42,000 tons. The lack of cars was almost totally responsible for this decrease in production, the hours lost from car supply amounting to 1347. Total hours worked were 5388 and hours lost from labor shortage amounted to 410. The car supply this week shows no improvement and operators in this district are up in arms.

Clarksburg, W. Va.

An interesting and well attended meeting of the Northern West Virginia Coal Operators' Association was held Tuesday, Aug. 13, at the Waldo Hotel. Coal men representing the Clarksburg Fairmont and east West Virginia fields were in attendance. Topics pertaining to car distribution, routing and increased production were before the meeting for discussion.

The executive committee of the association discussed routine matters pertaining to the affairs of the Association. F. J. Patton, secretary of the association, reported a full attendance of the members of the committee. At the conclusion of the business meeting, numbers of the visiting operators took advantage of the opportunity to visit some of the mines in the vicinity of the city. Automobile parties were made up and many of the local mines were inspected.

The evening session was featured by a banquet at the Waldo, when the local coal men, headed by "Uncle" Dan Howard, entertained the visiting operators. J. M. Orr acted as toastmaster and called on a number of the prominent operators present to discuss various phases of the coal situation. D. R. Dawson, district representative of the United States Fuel Administration, was the first speaker. He discussed the car supply problem and distribution of available cars. R. B. Isner, of Elkins, member of the executive committee, discussed the financial affairs of the association. He was followed by F. J. Patton, of Fairmont, secretary of the Association, who stated that there were from 500 to 600 operators in the northern West Virginia coal fields and it was the aim of the association to have a one hundred per cent membership.

Other speakers were Lloyd Bailey, representing the Pennsylvania-West Virginia Coal Company; "Uncle" Dan Howard, president of the operators' association, and Harry W. Sheets.

Ottawa, Canada

An important statement impressing upon the public the urgent necessity of getting in supplies of soft coal immediately was made on Aug. 14 by C. A. Magrath, Canadian Fuel Controller. He declared that the seriousness of the situation did not seem to be appreciated, as evidenced by the fact that domestic coal is not being purchased in sufficient quantities, and he could not emphasize too strongly the danger of actual suffering in the cold months if action is not taken at once. He drew particular attention to the fact that the allotment for the Canadian West, as recently announced by Mr. Peterson, the Deputy Controller, was entirely contingent upon the coal being available in the United States. Since April the allotment of anthracite coal for Canada has been cut by one million tons, and the United States has restricted supplies all over that country.

The Western allotment of anthracite is only half the amount normally consumed, and this will be available provided it reaches the head of the Lakes, but even this is not an assured fact. As long as the war is on no guarantee can be given regarding anything in the matter of improved coal. Unnecessary hardship will result if the Western people do not follow the advice given that 50 per cent of soft coal must be in before any hard coal is supplied. "Western mines can produce and the railways can deliver domestic fuel," continued the controller, "therefore I positively and absolutely refuse to be responsible this winter if people suffer."

In reference to complaints made as to excessive prices charged for coal in Winnipeg Controller Magrath said that he was prepared to take drastic action in any specific cases brought to his attention where the law had not been complied with.

PENNSYLVANIA

Anthracite

Hazleton—Two powerful electric pumps will be installed at the No. 5 colliery of the C. M. Dodson Coal Co. at Beaver Brook. The pumps will be placed in concrete beds and can be operated even if entirely flooded.

Hazleton—The Lehigh Valley Coal Co. is planning for increased stripping operations in the Tomhicken section. Negotiations have been completed with the township officials of Hazle Township providing for the changing of the course of one of the township roads, in order to facilitate the proposed work.

Hazleton—The Harleigh-Brookwood Coal Co., whose Harleigh mines were drowned out recently when Harleigh Creek broke through its bed into the underground workings, has made arrangements to divert the course of the stream, build a new channel for it and pump out the flooded gangways. The company, which is controlled by the Madeira, Hill & Co. interests, lost its $200,000 breaker recently through fire, and the Lehigh Valley Coal Co. was preparing its tonnage for market when the place was filled up by the creek.

Freeland—The mining companies have been asked by the Federal authorities to state their material requirements for 1919 and six months of 1920. Shipments of nails, iron, and other mine and mill supplies are held up, and firms must depend on local jobbers at increased prices.

Shamokin—The first arrest under the Federal law, prohibiting agents from one industrial field inducing men to leave for another, was made on Aug. 13 by Federal officers when they jailed Peter Jalinski, an employment agent for West Virginia soft coal corporations. Jalinski, a former resident of Shamokin, came here and induced more than a score of miners and mine laborers to accompany him back to West Virginia upon promises of unusually high wages.

Trevorton—In keeping with its pledge to increase production, the Susquehanna Collieries Co. has reopened the Coal Run slope, which was abandoned here 30 years ago. Coal from this slope will be run underground for two miles to the Luke Fidler colliery, where it will be prepared for market.

Eckley—Miners showed their patriotic interest in coal production operating the Lehigh Valley Coal Co. colliery full-handed, even though the funerals of two of their comrades killed at work were in progress. The Lehigh Valley Coal Co. sent six miners to each service, paid their wages for the day and contributed $150 to the victims' families, for expenses.

Pottsville—The Mammoth vein, so named because of its great thickness, being 40 ft. at some places, is to be stripped by the Darkwater Coal Co. Several million tons of coal will be easily accessible and will be had at little cost. The company has obtained the surface rights to a number of pieces of real estate, upon which dwellings, erected many years ago, will be vacated and razed, after which the stripping of the earth and clay will be begun. The coal will be prepared at one of the company's breakers nearby. James B. Neale, fuel advisor to Doctor Garfield, is head of the concern.

Wilkes-Barre—Announcement has been made by the Susquehanna Collieries Co. that the annual field day of the company generally held at Shamokin will not be held this year, but that instead contests in first aid will be held by the various divisions. This will do away with any possibility of curtailment of output, but will allow the men to have their contests, which will be held in the evening.

Hansford—Notices received on Aug. 9 state that the Government has let down the bars against the importation of Mexicans for railroad and mining jobs. The measure is merely for temporary relief, but the men can be brought to help out in the anthracite region where the labor situation has hampered coal production and transportation considerably. Heretofore they could not be used in any collieries, except those in the Middle West, which mine lignite, a semi-bituminous grade.

Millersburg—With the present demands for coal it seems that the plan in vogue for years for coal-mining companies to use coal monuments in front of their offices is in discard for the present. A large piece of coal aggregating in weight about two tons, which has stood for many years in front of the offices of the Susquehanna Coal Co. has been removed to the company's breaker at Lykens and reduced to coal of marketable size. The company has recently given up its Millersburg office.

Bituminous

Irwin—The Jamison Coal and Coke Co. is sinking a shaft on the Hile farm, adjoining Pleasant Unity, and will mine the Thaw estate coal—600 acres. On the Alexander Graham farm a new town is being built and a railroad spur is being built to the mines.

Madera—The Blue Run Coal Co., which began operation here on the William Semple and Bailey lands on June 14, is shipping coal. The operation employs 14 men. Coal is conveyed to Madera on a 5-ton Republic truck and is there loaded in box cars on the Pennsylvania R. R. As soon as the side track is extended to the mines the coal will be loaded from the tipple.

Smithton—E. W. Ruth, John Parchini and Bercon, Ben McLain and Paul Jullinal, four wagon-mine operators of Smithton, have had their mines closed down permanently by the Fuel Administration because they persisted in loading coal that contained rock, slate, sulphur, fireclay, shale and other impurities.

Harmarville—With the death of two men in the Allegheny General Hospital, Pittsburgh, the total death list due to the explosion at the mine of the Consumers' Mining Co. recently has been increased to eight.

VIRGINIA

Coeburn—The Twin City Coal Corporation, recently incorporated with a capital of $90,000, has perfected its organization, and is planning for the immediate development of about 300 acres of coal properties. The works will have an initial capacity of about 150 tons daily. J. P. Lay is president.

WEST VIRGINIA

Wyatt—In connection with extensive improvement at the local plant of the Consolidated Coal Co., a large, new, two-story coal tipple is being constructed. It is said that when completed, this tipple will be one of the most modern in this section.

Wheeling—A total of about 4500 acres of coal land, ranging in price from $110 to $135 per acre, lying partly in Pennsylvania and partly in Brooke County, West Virginia, has been purchased by W. W. and J. F. Luce, of Bellvernon, Penn., from J. A. Beall, of Pittsburgh. It is the intention of the purchasers to build branches from the Pennsylvania and the Wabash railroads, and more mines, in addition to those already in operation, will be opened.

Charleston—The mine formerly operated by the Little Queen Coal Co. at this place has been purchased and is now being operated by N. J. Wood, of the Dickinson Fuel Co., of Charleston.

McComas—A new mine is being operated by the American Coal Co. at this place, under the supervision of J. Tracy Walker, superintendent, 25 houses for miners also being under construction here. This company succeeded in increasing its July output 5000 tons over its June output.

ALABAMA

Cullman—M. W. Bush, Birmingham, and associates, have acquired approximately 16,000 acres of coal lands in the Bremen basin section of Cullman, and are planning for early development operations.

Birmingham—The New Castle Coal Co. is planning to rehabilitate its old Lehman mine at New Castle, and will construct a modern tipple and equipment for the handling of coal from the opening. A Ramsay rotary dump will be installed, which will necessitate the employment of only one man in the handling of the coal on the tipple. This labor-saving device is an invention of Erskine Ramsay, one of the best-known coal operators of the country, who represents Alabama in the directorate of the National Coal Association and is also a member of the executive committee of that organization.

KENTUCKY

Hazard—The Kenmont Coal Co. is at the present time making a new 6 ft. opening in the upper vein of coal and expects to increase its output to 20 cars a day.

Lexington—The White Ash Coal Co., recently incorporated, has purchased the lease of the Mike Branch Coal Co., in Lee County. The lease contains 900 acres with two openings and full mining equipment. The production now is four cars a week and the new company intends to increase that to 15 at once.

Hawesville—The Central Kentucky Block Coal and Mineral Co., recently incorporated with a capital of $200,000, is planning for immediate work on the development of approximately 2000 acres of coal properties in the Hawesville district. It is proposed to install the necessary equipment to provide for a capacity of 500 tons daily. D. G. Duncan is secretary.

Harlan—Operators of Bell and Harlan Counties, and some operators in West Virginia, have been seriously handicapped by the failure of the Kentucky Utilities plants at Varilia, Ky., and the Pocket Field, of West Virginia, to furnish power to concerns buying power. About 75 of the mines along the Louisville & Nashville in Bell and Harlan Counties have been down on and off for three weeks or more due to failure of power, but the situation has grown worse. The power company claims failure of machinery concerns to make deliveries of repair parts, and has been asking aid of the Fuel Administration to help in getting things moving. Investigations have shown numerous delays in transportation, small parts being held by express companies unnecessarily, and some parts being practically unobtainable.

TENNESSEE

Briceville—The Cross Mountain Coal Co., which recently filed notice of an increase in its capital from $400,000 to $500,000, is now developing about 3000 acres of coal properties in the Briceville section, with daily output of approximately 600 tons.

INDIANA

Washington—The Superior Coal Co. has taken leases on 2500 acres of coal land in the Barr township oil field and will begin developing the second vein as soon as a mine can be opened. The vein is 8 ft. in thickness, as proven by numerous oil wells drilled in this section, and lies at a depth of from 250 to 300 ft. The company is also increasing the size of its mines at Cannelburg and Montgomery.

Evansville—The Commerce Coal Co. owned by capital in this city, is opening two new coal mines near Jacob's station, which will have a capacity production of 1000 tons of coal a day.

Vincennes—The eight mines of the Knox County Coal Operators' Association produced during July 323,887 tons of coal. The largest previous record for a month was 293,499 tons. This result was accomplished in face of the fact that this particular field lost 350 hours, or more than 21 per cent. of the working time, on account of the car shortage

ILLINOIS

Carlyle—The five mines of Clinto County produced 1,429,569 tons of coal in the fiscal year ending June 30. Two miners were killed and 15 injured.

Lincoln—Miners of this community who have gone into the service were honored at a service flag dedication Sunday, Aug. 1, at Latham Park. Frank Farrington, of Springfield, president of the United Mine Workers of Illinois, and L. B. Stringer, of Lincoln, were the speakers.

Belleville—St. Clair County produced in the fiscal year ending June 30, 7,916,674 tons of coal, an increase of 2,217,324 over the preceding year, according to the annual report of Thomas Wright, state mining inspector. This production involved the death of 17 miners, eight of whom were residents of Belleville. The county has 5800 miners, 53 shipping mines and 15 local mines. The latter produced 106,925 tons.

OHIO

Toronto—To show the enterprise of coal miners in supporting the Government in its urgent demand for fuel, it is interesting to note that one James Emory, of this place, minus both legs, has secured artificial limbs and is again engaged at his former occupation as a coal miner in one of the mines in the vicinity of Steubenville.

ALASKA

Anchorage—The Chickaloon Coal Co., which has been developing its property at the head of Cook Inlet for the past six months, expects to start shipping coal to the states next year. Walter Gompertz is superintendent of the property.

Cordova—Folcon Joslin, who recently obtained the first government coal land lease in the Bering coal field, states that development work is to start at once with the construction of a short railroad from the mine, which consists of 2400 acres between Shepard Creek and Lake Kushtaka, to the Copper River & Northwestern R. R., a distance of 65 miles. The government lease requires that $250,000 in development work be undertaken. The company is known as the Bering River Coal Co. F. R. Van Campen is superintendent.

WASHINGTON

Bellingham—The railroad to the Cokedale Coal Co. property in Skagit County has been completed, as will be the new power station in a few days, and as soon as this is ready to operate the coal-cleaning machinery the mine will be ready to ship.

Seattle—The Federal Fuel Administration has permitted a raise in the price of Nanoose coal to absorb a raise in price granted by the Canadian Fuel Administration to the mine operators of Vancouver Island. The lump coal is advanced 65c. per ton and nut and pea 25c. A similar raise in the price of South Wellington coal has also been permitted.

Personals

H. J. Kennard, of Beyer, Penn., formerly superintendent of the Coal Run Mining Co., of Coal Run, Penn., has resigned to take charge of the Kurtz Coal Co. mines near Sangamon, Penn.

W. B. Millgate, who has been mining inspector in District No. 11, which includes Harrison and part of Jefferson County, Ohio, has resigned to become superintendent of the Fisher mine, between Dennison and Bowerston.

Daniel E. Russell, vice president of the Delaware, Lackawanna & Western R. R. Coal Dept., has resigned, on account of ill health.

Clarence W. Watson, chairman of the Board of Directors of the Consolidation Coal Co., Charleston, W. Va., and a lieutenant colonel in the Ordnance Department of the War Department has been nominated by the Democrats of West Virginia for the United States Senate.

H. H. Elkins, who has been superintendent of the Clarkson Coal Co.'s mines at Provident and Fairpoint, Ohio, resigned recently to accept the superintendency of the Occo Coal Co's mines between Bannock and

Lafferty. No one will be appointed to fill the place vacated by Mr. Elkins, but John Davis will continue to superintend No. 1 at Provident and John Norton No. 2 at Fairpoint.

E. P. Dillon, manager of the power division, New York office of the Westinghouse Electric and Manufacturing Co., has resigned to become general manager of the Research Corporation of New York. Mr. Dillon came to the Westinghouse company in 1909, having been previously connected with various mining and electrical companies in Colorado. In 1917 he was transferred to the New York office as manager of the railway and power division. For several years he was assistant to the manager of the railway and lighting department at East Pittsburgh, being in charge of power house and apparatus work. He was transferred to the New York office as manager of the railway and power divisions in 1917.

New Incorporations

Calla, Ky.—The Progressive Coal Co. Capital, $10,000, has filed amended articles increasing capital to $30,000.

Lennut, Ky.—The No. 4 Superior Coal Co. Capital, $10,000. Incorporated by C. S. Luttrell, M. Luttrell and J. W. Reedy

Harlan, Ky.—The Shawnee Gas Coal Co. Capital, $90,000. Incorporated by C. E. Ellison, E. N. Howard and W. W. Eager.

Knoxville, Tenn.—The Cross Mountain Coal Co. has filed an amended charter increasing its capital from $400,000 to $500,000.

Central City, Ky.—The McHenry Coal Co, Capital, $210,000. J. H. Small, L. L. Stewart and A. J. Early. Incorporated to handle western Kentucky Coal

Chattanooga, Tenn.—The White Coal Co. has filed amended articles of incorporation, increasing its capital stock from $10,000 to $50,000, and plans changing name to the Christian Coal Company.

Hartford, W. Va.—The Mason Coal and Chemical Co. is planning to increase the present capacity of its plant. New mining cars will be installed and equipment purchased. A. D. Williams is president.

Bellaire, Ohio—Klee Coal Co. has been incorporated with a capital of $12,000 to mine and sell coal. The incorporators are William Goldsmith, John E. Klee, Marker Meager, Roscoe Klee, John Klee, Jr., Alva Klee and Howard Klee.

Queen Shoals, W. Va.—The Fire Block Coal Co. is planning for immediate work on the development of about 1500 acres of coal properties recently acquired in the Queen Shoals district. J. W. Miller and A. J. Saltzer, both of Charleston, head the company.

Carbon Hill, Ala.—The Rush Coal Co. has been organized and is planning for the immediate installation of machinery and equipment for the development of about 80 acres of coal properties in the Carbon Hill section. It is planned to have an initial capacity of about 35 tons daily. S. A. Threadgill is president and manager.

Clarksburg, W. Va.—A $50,000 coal company to be known as the Catherine Coal Co. has been organized to mine coal in Eagle District, Harrison County, with offices in Clarksburg. The company was incorporated by Carl L. Hornor, Robert L. Hornor, Henry W. Thacker, Walter B. Hornor and Artie M. Hornor, all of this city.

Louisville, Ky.—Among the recently filed corporation articles were those of the Panhandle Coal Co., Jackson, Ky.; capital, $60,000; incorporators, W. O. Bender, E. O. Bailey and E. I. Hawkins. Williams Oil, Gas and Coal Co., Red Bush; capital, $26,000; Leo Williams, L. T. Williams and Alfred Williams. Powell Coal Co., Whitesburg; capital $10,000; James P. Lewis, C. B. Sturgill and C. B. Powell, Laura Lee Coal Co., Williamsburg; capital, $300; Isham Lawson, Nancy Lawson and Squire Rains.

Industrial News

Louisville, Ky.—Notice of dissolution has been filed by the Dougherty & Lanning Coal Co., and its business has been taken over by the Harvey-Jellico Coal Co.

Knoxville, Tenn.—The Green Mountain Coal Co. has filed notice of an increase in its capitalization from $400,000 to $500,000, to provide for business extensions.

Erie, Penn.—The Burke Electric Co. announces that C. D. Miller is now manager of its Buffalo branch sales office at 509 Morgan Building, Pearl and Niagara Streets.

Great Lakes, Ill.—The United States Government, Navy Department, has awarded a contract to the Warner Construction Co., Chicago, Ill., for the construction of a new coal yard at the local naval station, in connection with other work, to cost $69,228.

Chicago, Ill.—The Chicago Great Western R. R. has awarded a contract to the Railroad Water and Coal Handling Co., Chicago, for the construction of a new coaling station of 100 tons capacity at Kansas City, Mo. The structure will cost about $20,000.

Charleston, W. Va.—Having increased its capital so as to be able to open a new mine, the Marsh Fork Coal Co., of which T. E. B. Siler, of this city, is president, is preparing to begin the shipment of coal from Jarrolds' Valley within the next two months.

Charleston, W. Va.—Owner of a large acreage of coal land in Clay County, the Lima Coal Co. of Lima, Ohio, has made application for a siding on the Coal & Coke Ry. at the mouth of Leatherwood Creek, near Hartland, with a view of developing its holdings.

Charleston, W. Va.—Equipment is being installed by the Big Bottom Coal Co. of which J. S. Cheyney is president, on its property on Campbells Creek, where in a few weeks the company will begin taking coal from the Lewiston seam. James Raisbeck is general manager.

St. Louis, Mo.—Walter A. Zelnicker Supply Co. has recently added to its sales force Henry Stroh. For the past ten years Mr. Stroh was connected with the Elliot Frog and Switch Co., prior to which time he was associated with the Republic Iron and Steel Co., both of East St. Louis.

Concrete, Wash.—The Superior Portland Cement Co. has started work removing its oil burners preparatory to installing coal burners, which last year were taken out for the crude oil apparatus. This is only one of the large Washington manufacturers who were compelled to make such a change as a result of the scarcity of oil.

Salt Lake, Utah—With a membership of more than 150, representing every section of the state, the Retail Coal Dealers' Association of Utah was organized recently at the Newhouse hotel. Elias S. Woodruff, of Salt Lake, was elected president, John Farr, of Ogden, vice president, and S. L. Billings, of Salt Lake, temporary secretary and treasurer.

Charleston, W. Va.—The Gauley Coal Co. is installing a complete new unit to its power plant at Greendale at an estimated cost of $20,000. In addition to the installation of motors and machines in the mine, E. G. Beddison, the superintendent in charge, is seeking a new or good second-hand Goodman shortwall mining machine and one 8- or 10-ton haulage motor.

Louisville, Ky.—Wiley B. Bryan, fuel administrator for Kentucky, recently issued an order which provides that no operator, licensed distributor or retail dealer shall sell, ship or distribute any coal for domestic purposes to any person having access to an adequate and available supply of wood, except by permission of a member of the fuel committee for the county where the delivery of such coal is to be made.

Louisville, Ky.—The Harlan Coal Co. has filed suit in the Circuit Court against the King Coal Co. for $5000 damages, alleging a breach of contract in refusing to furnish its output of coal to the Harlan company, and it further asks an injunction to prevent the defendant from selling or shipping coal to any other agents or persons during the life of the contract made Oct. 20, 1917, to last until after the war is over. The plaintiff charges that the defendant refused to accept orders sent to it.

Providence, Ky.—A number of citizens of this city have formed a company for the development of coal lands, under the firm name of the Montgomery Mining and Development Co., and have filed articles of incorporation. The company has purchased the mine and equipment of Jesse Brantley for $2000 and has already started work. It is the intention of the company to put a number of improvements in the near future. James F. Parker has been made general manager of the company.

San Francisco, Cal.—The following are the coal imports into this port for the first six months of the present year as compared with last year: From foreign ports, 75,720 tons 1918, 138,281 tons 1917; from domestic ports, 61,417 tons in 1918, 90,164 tons for the six months of 1917, or a grand total of 137,137 tons for the six months of the present year as compared to 228,445 tons for the same period last year. Coke recepits by rail for the same period were 1710 tons and 2405 tons respectively.

Toledo, Ohio—Activity at the docks of the lower lake ports still continues, stimulated by the lake shipping priority order recently issued. During the week ending Aug. 10 the Hocking Valley at its Toledo docks loaded 169,928 tons as compared with 164,602 tons the previous week, making a total of 2,281,986 tons for the season. During the same week the Toledo & Ohio Central loaded 78,000 tons as compared with 73,000 tons during the previous week, a total of 1,028,000 for the season.

Cleveland, Ohio—The Chicago Pneumatic Tool Co. announces that contract has been let and work started on the erection of an up-to-date addition to its Cleveland plant, which is planned to double the present output. It is expected that work will be completed on the building itself about Nov. 1. The necessary equipment has been ordered and it is believed will be delivered and ready for installation by the time the building is completed, so that the additional production contemplated will be available soon thereafter.

St. Louis, Mo.—The St. Clair Coal and Mining Co., which supplied the city with coal last year, has been awarded a renewal of the contract at the same price as last year—$2.30 at the mine—on all preparations except screenings, which are to be furnished at $2.05. The contract, which runs not to exceed 13 months from Sept. 1, provides for fueling all the power plants of the city. The freight from the company's mines near Belleville is 95c. per ton and the delivery cost is 75c. per ton. The requirements are about 130,000 tons.

Cincinnati, Ohio.—The Central Frog and Switch Co. was recently organized with George Ashton as president and E. R. Heitzman as secretary and treasurer. Both men were formerly associated with the Cincinnati Frog and Switch Co., Mr. Ashton serving it in the capacity of vice president and chief engineer and Mr. Heitzman as secretary and treasurer. Mr. Ashton has been affiliated with the frog and switch business for 25 years. The new company is erecting a large plant along the Norfolk & Western tracks in the Hyde Park section of the city.

Columbus, Ohio—A. W. Kuhns, who has been sales manager in charge of the Columbus office of the Peacock Coal Co., has resigned and has purchased an interest in the W. A. Woods Coal Co., of Cleveland, which has established a Columbus office with Mr. Kuhns in charge, as treasurer of the company. The Columbus office will be located in the Huntington Bank Building. It will job all Ohio mined coals. At the same time the Columbus office of the Peacock Coal Co. has been discontinued, as the product of the company has been sold for more than a year in the future.

St. Louis, Mo.—An agreement has been reached between Regional Director Bush and city officals for the use of the municipal free bridge by the government-controlled railroads. The Government will determine what rentals are to be paid by the railroads to the city for using the bridge and whether they will be permitted to continue charging the 20c. a ton differential on coal. Bush plans to have the Government expend between $250,000 and $300,000 in making connections with the bridge approaches on both sides of the river. It is intimated that he may also recommend a more elaborate system of approaches which will cost a great deal more.

Columbus, Ohio—Ohio operators have been asked by the mine supply and equipment department of the production division of the Federal Fuel Administration to make up their budget for materials and supplies that will be needed in their mines during the year 1919. It is pointed out that this is to be done in order to facilitate the filling of the orders. Efforts were made as early as June 21 to gather this information through the National Coal Association, but the results were disappointing and now the work is to be done more systematically. Operators are urged to comply with the request at once in order to keep up the coal production to the highest possible point. Detailed instructions are given for filling out blanks sent by the Fuel Administration to the operators. Under a recent ruling of the Priorities Division of the War Industries Board an Automatic Priority in Class A-6 is granted on all manufactures of materials, equipment and supplies for the operation and maintenance of coke-oven plants and mines employed in the production of fuels.

MARKET DEPARTMENT

Weekly Review

Production Decreases While Demands Increase—Bituminous Coal 14,500,000 Net Tons Behind Schedule—Car Shortage Again to the Fore—Anthracite Production Keeps Up Well—Lake Shipments a Cause for Disappointment

IN the face of ever-increasing demands for bituminous coal, production recedes steadily week by week from the 13,286,000 net tons reported in the record-breaking week ended July 13. Estimates made at the beginning of the coal year for the tonnage of fuel necessary for essential uses have proved to be too low, the latest revised figures showing that every possible effort will have to be made by the coal-mining industry if the war program is not to suffer a setback. The requirements for the Navy, for instance, were originally fixed at 3,500,000 net tons for the year. It now is estimated that Uncle Sam will need at least 8,000,000 net tons for his vessels before the end of 1919.

An idea of how fast the Navy is consuming fuel may be had from the fact that the demand in July from this source had risen to a 6,000,000-ton-a-year basis. The shipyards, too, are speeding up production to such an extent that the 10,000,000 net tons considered a liberal allowance for the Shipping Board on Apr. 1 have been increased by 3,000,000 tons. Another phenomenal increase is in the demand for bunker fuel. At the beginning of the coal year 13,500,000 tons were assigned for this purpose, with the thought that this amount would prove adequate. The estimate has now risen to 21,000,000 tons. When to the foregoing figures is added the coal needed by plants that have been enlarged, and the additional fuel required to keep a large percentage of industries operating on a 24-hour basis, it can be seen that the problem confronting the soft-coal mines is of no mean proportions.

For the week ended Aug. 10 (the latest statistics available), the output of bituminous coal is estimated at 12,274,000 net tons. This means an average production of 2,046,000 net tons a day for this period, which is 54,000 net tons below the daily output established as a minimum. To emphasize the seriousness of the situation still further—the soft-coal mines are now 14,500,000 net tons behind schedule, and it is a foregone conclusion that they will never catch up.

The causes for the fall in output seem to be divided between car shortage and labor unrest, with the greater part of the blame attaching to the former. Record production can only be achieved when the railroads manage to keep an adequate number of empty coal cars moving to the mines and the transportation of loaded cars is speeded up. This statement is substantiated by the fact that the peaks in the coal production chart result when the railroads operate at maximum efficiency. Operations in the Pittsburgh district are short of 200 cars a day, and on Aug. 16 many of the mines in that region were at a standstill for want of cars. In the Kanawha and Coal River districts of West Virginia car shortage was responsible for the loss of 1347 productive hours during the week ended Aug. 10. In Alabama, too, the lack of cars caused a decided decrease in output.

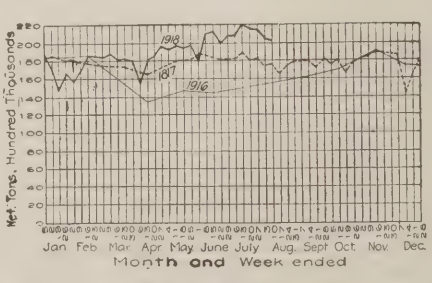
Despite reduced labor forces, the output of anthracite coal continues to keep well ahead of the quantity mined last year. Hard coal shipments during the week ended Aug. 10 totaled 2,051,933 net tons, a decrease of 6.4 per cent. compared with the week preceding. The total output of anthracite coal in July amounted to 7,084,775 tons, an amount exceeded only twice before; but what is even of more importance, virtually the entire tonnage of anthracite mined for the first quarter of the coal year—April to July—is in the hands of the consumer.

Nothing should be tolerated that will interfere with anthracite production if the public is to be supplied with coal. There is evidence that Hun propaganda is rife in the hard-coal regions—in the shape of both covert and open acts calculated to create discord in the labor ranks. The mining force should by every possible means be maintained at its present figure, whether against the draft or other depleting agencies.

Shipments of soft coal to the lakes grow more and more disappointing. It is feared that the Northwest will not get over 25,000,000 tons, instead of the 28,000,000 aimed at. The first eleven days of August saw lake shipments of bituminous—exclusive of vessel fuel—only 1,535,996 tons. The Fuel Administration schedule calls for 4,900,000 tons. July closed 1,000,000 tons behind, and it appears that August will add about 1,250,000 tons to this deficit. For the week ended Aug. 17 the estimate of shipments to the Northwest is 1,020,000 tons. The Pittsburgh district has not been able to respond to the 1600-car-a-day order, due to the unsatisfactory car supply referred to earlier in this review and a marked shortage in motive power.

COAL PRODUCTION

The production of bituminous coal during the week of Aug. 10 decreased 278,000 net tons, or 2.2 per cent. and recorded the fourth successive week of decreased output. The decrease in production during this period was equivalent to 1,000,000 net tons, or 7.6 per cent., below the record week of July 13, when production reached 13,286,000 net tons, and makes necessary an output of 14,500,000 net tons during the balance of the summer months to make up the deficit for the coal year to date. The output during the week of Aug. 10 (including lignite and coal coked) is estimated at 12,274,000 net tons as against 12,552,000 net tons during the week of Aug. 3 and 10,636,000 net tons during the current week of 1917. The average production per working day during the week of Aug. 10 is estimated at 2,046,000 net tons as compared with 2,092,000 net tons during the week preceding and 1,773,000 net tons during the week of Aug. 10, 1917. The daily average during the current week fell 54,000 net tons, or 2.6 per cent. behind the daily summer requirements established by the United States Fuel Administration.



Shipments during the past week decreased from all districts with the exception of southwest Virginia, Alabama and the district including Illinois, Indiana and western Kentucky. The increase from southwest Virginia amounted to 24.3 per cent., from Alabama 11.4 per cent. and from Illinois, Indiana and western Kentucky 2.2 per cent. Material decreases during the week were as follows: Central Pennsylvania, 3.2 per cent.; western Pennsylvania, 4.8 per cent.; Cumberland-Piedmont and Somerset, 8.4 per cent.; Fairmont, 9.3 per cent.; Ohio, 6.9 per cent., and Tennessee and Kentucky, 8.8 per cent.

Anthracite production during the week of August 10 is estimated at 2,051,933 net tons, a decrease compared with the week preceding of 6.4 per cent. Shipments during the same week totaled to 36,870 carloads, decreasing 7 per cent. Total production during the coal year to date is estimated at 37,709,447 net tons, an increase over the same period of last year of 2.1 per cent.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: July 20	July 27	Aug. 3	Aug. 10
Bituminous shipments, 123 roads	229,770	228,231	220,940*	215,996†
Anthracite shipments, 9 roads...	40,664	40,942	39 632	36,867†

* Revised from last report. † Subject to revision.

Beehive Coke—Production of beehive coke in the United States during the week ended Aug. 10 is estimated at 602,000 net tons, a decrease compared with the week preceding of 12,000 net tons or less than 2 per cent. The average production per working day is estimated at 10,000 net tons as against 102,000 net tons during the week ended Aug. 3. Operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week of Aug. 10 at 358,986 net tons, and the operation of their plants at 70.3 per cent. of their present capacity as against 76.1 per cent. during the week preceding. Production was limited during the week by yard labor shortage, slight mine disability and other causes not reported. The same operators produced 202,150 net tons of coal.

Byproduct Coke—Operating conditions in the byproduct coke industry in the United States improved slightly during the week ended Aug. 3, the plants operating at 91.5 per cent. of their present capacity as compared with 90.6 per cent. during the week preceding. Material gains occurred during the week in Kentucky, Maryland, Minnesota, New York and Ohio. Improvement was brought about in Kentucky and Maryland by repaired plants, in Minnesota by better market conditions and in New York by better labor conditions. Tennessee was the one state reporting a decrease in production. The week of Aug. 3 was the first time the operators of the country reported a market for all coke produced, the operators in Minnesota, the lone state reporting loss of time due to that factor during the past few months, finding a market for their entire production.

BUSINESS OPINIONS

Marshall Field & Co.—The feature of the wholesale dry goods business for the week was the large business done in domestic cottons. Road sales for immediate delivery showed a good increase over the corresponding week of 1917. Lines for spring of 1919 have not yet been offered. Customers were in the market in fewer numbers than last year. Collections continue good.

Bradstreet's—War orders dominate every line, and supplies for ordinary purposes are greatly curtailed. Conservatism in regular channels, whether flowing from damage to the corn crop in the southwest, from lessened demand for men's goods, from belief that prices have reached zenith point, or from restrictions placed upon so-called non-essentials, is thereby almost overshadowed. Indeed, the great majority of wholesale trade reports testify to continued good demand ruling, largely, however, on government account, exceptions to this being noted in dispatches from districts of the southwest where both cotton and corn have been hurt by drought. Retail trade is fair to good for a midsummer period, and the same is true of collections, except from the southwest.

American Wool and Cotton Reporter—That there will be enough cotton the coming year is undoubted, at least in some quarters, and it is felt that the market will later be bearish. It is predicted that those who are relying on increased facilities for shipment will be mistaken. Other factors will also come into play later. Mills are not buying cotton at the present time because they are not in the market to make goods. They are waiting for prices to be fixed. Basic prices have been announced, but there seems more or less stagnation because other prices on goods in general have not been fixed. The woolen goods market is decidedly mixed. Figures show that there ought to be much wool available for the production of ordinary fabrics, but facts or intimations given out appear to show that at least no large supply can be expected, and some believe that there will be no apportionment at all. It is not surprising, therefore, that some economical producers could make a great effort to secure Government orders up to their capacity. The question of importance is, however, what other producers will be able to do in order to keep machinery in operation.

Atlantic Seaboard

BOSTON

Further conferences in Washington show the strength of New England's case. Rumored that no curtailment is to be ordered. Great need of volume shipments continuously until Nov. 1 seems better understood. From Hampton Roads and from central Pennsylvania shipments continue on the July basis, with occasional increase for short periods. Box cars continue to come forward from the central Pennsylvania district, but already there are signs of this equipment starting west for grain. By Sept. 15 the number of box cars available will be much reduced. Steamers at Boston and Portland being unloaded more promptly. Delays begin to appear at Hampton Roads and at Baltimore. Volume of high priced coal by water has a marked effect upon buyers. Meanwhile, Government requirements increase by leaps and bounds. Slack demand for anthracite steam sizes. Reading barges may occasionally load at Port Reading.

Bituminous—Pursuant to earlier conferences in Washington Mr. Storrow and a few members of his staff were again at the capital last week, this time to show by actual figures that New England is not as well stocked as "everybody knows." It takes most persistent argument and conclusive figures to make others who are unfamiliar with conditions in New England to understand why what would be a sufficient reserve for industries in eastern Pennsylvania would by no means be adequate for this territory to enter the winter months on any safe basis. It appears that now this phase of our situation is looked upon more intelligently and the great need of building up reserves in New England is better recognized. Unless our railroads and other essentials can accumulate the next 60 days at least to the extent they did last year there is ground for much anxiety. When, from weekly reports, it is seen that any plant has more than a reasonable supply, action is at once taken to divert at the gateways all coal originally consigned to that plant all-rail, and when distributors of water coal submit the disposition of cargoes the names of such consignees are taken from the list. In this way deliveries are carefully supervised, although it is by no means an easy matter. The difficulty is that every buyer is reaching out in every direction to get coal if not at one price then at another, and to have anything approaching scientific distribution would require a small army of inspectors and others with authority to act.

Weekly deliveries from the central Pennsylvania district are now from 3800 to 4000 cars, but so far as figures can be had the movement has been at no time in excess of 4000 cars. The program on June 12 was for 4500 cars weekly and it does no harm occasionally to remind Washington that actual shipments on that order have averaged much less than 80 per cent. In other words, August receipts at the gateways continue about on the July basis and only for brief periods is there any noticeable increase. All box cars on the Pennsylvania railroad from the central Pennsylvania district are still considered free coal for distribution by the Fuel Administration. At times since the order went into full effect on July 22 the movement of box cars has reached 600 per week for New England. A better demand for coal in this equipment is now forthcoming from New York and eastern Pennsylvania and from time to time the number of cars for New England is somewhat reduced. Continued shipments of this kind can hardly be relied upon for more than a few weeks because it will soon be necessary for the railroads to send box cars west for grain. Already there are signs of this westward movement and it is freely predicted that by Sept. 15 there will be much less opportunity to get wagon coal. The more farsighted of the small consumers are gladly taking advantage of present opportunity and every car that comes forward helps that much the general New England situation.

Dumping at Hampton Roads continues also on about the July basis, although receipts at the piers have been more irregular. Steamers shifted from Baltimore to Hampton Roads have met with delays and there has been a lot of apprehension among New England buyers over demurrage charges that are likely to accrue. The lack of berth room at Boston and Portland that was the cause of detention at this end has now been cleared up by a better disposition of steamers as they arrive and from now on the delay is more likely to be at the loading piers. In this connection, the Shipping Board is now issuing semi-weekly announcements of port performance. Norfolk and Newport News, for the half week ending Aug. 12, had the best record for loading, 12 ships having been loaded and trimmed at an average of 34 hours and 42 minutes in port. Counting 21 ships unloading at Boston during the same period the average time in port was 116 hours and 30 minutes. It is expected that figures next week will show a material reduction in time required for unloading at this end.

Detention at Baltimore has also given cause for anxiety, especially during the past week. Several cases of heavy demurrage have followed and as this becomes known in the trade it grows more and more difficult to distribute the high-priced coal. Inland buyers who have had demurrage items as high as $2.50 on their coal invoices are getting increasingly shy of committing themselves on coal yet to arrive. With a few weeks' supply on hand they are more inclined to wait developments and take their chance of getting rail shipments or later by water when they think there will not be so great a risk of demurrage. This is unfortunate, for it is of greatest importance that every New England buyer take on coal today as fast as it can be shipped.

Anthracite—Receipts both by rail and water continue about as last reported. Water shipments are still seriously handicapped by submarine activities and movement is far short of 1917. It is rumored that Reading barges will occasionally load at Port Reading, N. J., rather than at Philadelphia, this being a part of a general effort to increase shipments to New England.

Broken and pea are the sizes in best supply and of late practically every cargo has had a proportion of these coals. Stove and chestnut are hard to get and apparently retailers will have to keep on accepting cargoes as they come. No shipper will today make any promises as to the assortment of sizes.

Notwithstanding all the campaign this year to induce steam users to take liberal tonnages of steam sizes of anthracite, the demand has notably fallen off. It is only natural that where consumers have been equipped to burn only bituminous they will confine their purchases to that rather than make further experiments with the different sizes of buckwheat. There is certain to be a renewed demand, however, when it is found that bituminous shipments are not forthcoming in anything like present volume.

NEW YORK

Anthracite situation in better shape and coal moving easier. Dealers complain of preparation. Church day curtails production. Long Island dealers insist upon larger shipments if famine is to be averted. Demand for bituminous equals production. More changes in tidewater pools. Navy Department wants more coal. Towing charges under investigation.

Anthracite—The situation is in better shape and the trade has taken on a brighter appearance. Coal is moving easier to this market and there is a better feeling all around. Even the public seems to be in a better humor, and it has been assured that everybody will have some coal before winter sets in. Reports show that for the week ended Aug. 16, 7069 cars of anthracite were dumped at the local docks as against 7004 cars dumped the week previous, a gain of 65 cars.

The retail dealers in this city are not all of the same opinion regarding distribution. Some of them believe that larger shipments of the domestic sizes should be permitted to come here so that they would be able to clean up on orders that have been on their books since April.

The producers have figured that nearly 9,000,000 persons have been provided with anthracite since Apr. 1 and that at the tidewater docks there was less than 113,000 tons of coal on the first of the month, which shows, they claim, that consumers are better provided for than ever before in August.

While conditions have improved in Greater New York the dealers in some of the small towns on Long Island claim that unless immediate action is taken whereby they can secure coal there will be many heatless homes this winter. The dealers complain of lack of shipments and say that they are not being given any increase over their 1916 tonnage, notwithstanding the increase in population.

The domestic coals, with the exception of egg, are moving easier and shippers report buckwheat No. 1 in better supply. Rice is in good demand while barley and culm are easy.

Local retail dealers are kept busy making deliveries but are handicapped by a shortage of help and the apparent indifference of their employees to work.

Current quotations, per gross tons f.o.b., tidewater, at the lower ports, are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck... 5.10	5.90
Egg.... 6.35	7.10	Rice.... 4.65	5.10
Stove... 6.60	7.35	Barley.. 4.15	4.30
Chestnut 6.70	7.45	Boiler.. 4.60	
Pea.....$5.20	$5.95		

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The demand continues brisk and with production failing to show any

substantial increase there is no surplus being accumulated at the docks. Some large consumers are more fortunate, however, and have been able to store small stocks to carry them over a few weeks or a month. With demands for more coal increasing owing to added industries, it is becoming more apparent that there is going to be a serious situation next winter unless something is done to increase production. Operators believe that there will be no further depletion in labor now that President Wilson has spoken and with an improvement in car supply they will be in a better position to maintain production.

There has been a further classification in Tidewater pools. Pools Nos. 13 and 29 have been eliminated and combined with Pool No. 18. Other changes are in contemplation. Many of the mines are being examined by the Navy Department, and this it is believed will result in many changes in the make-up of the pools.

Bunkering fuel is not in large supply in all of the pools. Some slight delay in loading is reported due to the failure of sufficient coal in the individual pool from which a vessel is being coaled, the rules providing that the coals from the various bunker pools must not be mixed. Owing to the increased shipping and the demand for bunker coals, it is believed that when the new classifications are announced by Tidewater Coal Exchange that many of the coals now classified as commercial coals will be found in the bunker coal list.

There was a decrease of 350 cars in the dumpings for the week ended Aug. 16, 6413 cars having been dumped as against 6763 cars the previous week. This market continues to be without free coals, practically all the coal coming here being spoken for before shipment.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite continues quiet, but demand heavy. Some improvement in shipments. New conservation measures. Fall prices cause anxiety on part of dealers. Stove and chestnut in strongest demand. Retail labor situation serious. Steam coals all taken. Some culm activity. Bituminous shipments in fair volume. Car supply complaint continues.

Anthracite—The week has been the quietest for some time. Probably the most encouraging sign is that shipments actually do improve in a small measure, and this has been the trend for several weeks now; as a consequence the trade continues to display a measure of optimism. While it is claimed the dealers will have some trouble satisfying their trade all fall, yet there are those who profess to believe that they will be in even better position by the time cold weather arrives. They further express the opinion that the troubles of last winter will not be repeated. The announcement of the local administrator that the dealers had stored 817,988 tons in the cellars of their customers up to Aug. 1 is encouraging. This tonnage is far in excess of that delivered up to the same period last year. Deliveries so far this month have been heavy and have considerably reduced the 833,157 tons reported by Mr. Lewis' office as being undelivered up to Aug. 1. In the suburbs the improved conditions are also becoming noticeable, as more than one dealer has got his deliveries in such shape that they are actually putting some coal into the cellars of new customers, a situation that none of them expected until late in the fall.

Stove and chestnut continue to be the short sizes locally and for some reason the former particularly so. Egg is short in the suburban sections, but comparatively easy in the city yards. A number of dealers are glad to see small stocks of pea accumulating. Buckwheat is noticeably easier, a situation that is not likely to continue beyond the present month.

The dealers appear to be as much worried over the labor situation as they are over the lack of coal. Retailers with heavy tonnages due them during the balance of the current coal year express the fear that in order to handle it they will be compelled to pay prohibitive prices for help. Several interviewed say they dare not reprimand employees who fail to report for work, let alone deduct a day's pay from those who have an increasing habit of taking a day off. That the situation will be critical before winter is admitted by all.

All shippers report their collections in the best possible shape, and those dealers who bore reputations for slow pay are now paying in advance when called upon. In truth the retail business is now practically on a cash basis. This is well illustrated by the new railroad ruling compelling payment of freights before delivery. This has in no way inconvenienced the dealers, as they are so anxious to get the coal in their yards they are prepared to pay the freight long before the coal reaches the city.

The steam situation remains unchanged. All coal is quickly taken and the demand for rice seems to be even heavier than before. The florists, who have had their supplies of bituminous cut to 50 per cent. having now received that quota are endeavoring to get rice to help out, and failing in this they are accepting quite a little culm. This latter grade remains quite free locally, with no price less than $1.25. Of course, it is not a question of price with them, for if they can use the culm in a mixture they are glad to get it at almost any price. Good shipments to outside points continue, although there has again been some interruption to tide shipments.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—Good tonnages are being reported from both the central Pennsylvania and West Virginia districts, although there continues to be some complaint as to car supply. This is probably a matter that will never be settled to the entire satisfaction of all, for it happens that the shipper who is the most pleased one week over car supply is in the depths the following week.

BALTIMORE

More even flow of bituminous continues under diversion orders. Improvement in anthracite deliveries, but big gap is yet to be filled. Dealers, stirred by labor situation, to ask greater margin of profit.

Bituminous—Aided by diversions arranged by the National Fuel Administration, by which some temporary stoppage is effected in the flow to preferred industries which have plenty of coal now on hand, the bituminous situation is easing off temporarily. This diversion to the account of the Maryland Fuel Administrator, for delivery by his direction to canners and other industries here that were in a bad plight, has been running from 15 to 25 cars a day recently. The result has been that a much easier situation is presented. The public seems somewhat educated toward receiving poor grade coal, and while loud kicks are sometimes made to purchasing agents or the fuel administrator, the impression is gaining ground that protests are of little avail. The experience of one business house is more or less characteristic. Supplied with two cars of coal, it was found that the fuel would not get up steam in the boilers. The purchasing agent appealed to at last got a line on a car of good grade coal and ordered it sent to mix with the other coal. In the meantime the house was forced to purchase some cart loads of soft coal from a retail dealer in order to keep the fires burning in the factory.

Anthracite—Retail coal men and fuel administration forces were pleased the past week to note an increased delivery of hard coal here. For the first half of August the receipts were nearly 50,000 tons, of which probably 32,000 tons were for distribution by retailers, the rest being steam coals for war industries. As monthly receipts of hard coal here have recently been below 60,000 tons, the increase is noticeably evident. Some tall figuring is being done here, however, in view of the fact that around 350,000 tons in orders still remain undelivered on the books of coal men with orders for 100,000 more tons in prospect before the middle of October. The yard reserve here is probably less than 30,000 tons. It will take receipts of close to 300,000 tons before the middle of October to enable distribution of the two-thirds by the time winter comes on in earnest.

The retail coal dealers at a meeting here with the Government labor representative told him they could not hold their laborers at 30c. an hour for a ten-hour day when he was picking them up and sending them to shipyards at 40c. an hour. If the labor depletion is not stopped the dealers say they will not be able to deliver sufficient coal to meet public needs even if the coal is shipped here. As a remedy it is suggested that a uniform scale of 35c. an hour be adopted by the coal men, that this not be put into effect until their margin of profit is increased to cover the move under order of the Fuel Administration, and that there be an agreement among coal men not to take labor from each other.

Lake Markets

PITTSBURGH

Car shortages more pronounced. Efforts to speed production. Practically no market transactions.

R. W. Gardiner, who has been distributor of Pittsburgh district coal, has been made production manager of the district and has appointed William McPherson his chief assistant. A series of meetings is planned, with prominent speakers, to outline the plans for speeding production. Mines will be grouped and miners and their families asked to attend.

Car shortages have been greater of late and production is less satisfactory. Lake shipments are behind the schedule, and as practically the only line trade that is receiving coal is that on the preference list, there is little opportunity to increase lake shipments except by increased production. Shipments of late from the Pittsburgh district have been, roughly speaking, one third lake, one third railroad and one third line.

Byproduct ovens are not receiving as heavy shipments as formerly, in a number of instances. Such shipments have been reduced, however, only when there was accumulation, the aim being still to furnish enough to maintain operations. The byproduct ovens want a large accumulation against the winter, as it is of prime importance that they have full production, not only because the coke is needed to make pig iron but because the byproducts are essential for the manufacture of explosives. Six months ago the Government showed much more interest in the latter than in the former, but its interest in the former has now become equally great.

Occasional allocations of coal are being made, but with the steady growth of the preference list such operations are not nearly as common as formerly. Open market transactions are rare and altogether exceptional, there being no regular movement. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.65, per net ton at mine, Pittsburgh district, with 15c. additional allowed to be charged by brokers.

BUFFALO

Anthracite growing scarcer. Lake shipments not heavy. Many restrictions. Bituminous quiet. Cars rather easy. Jobbers waiting.

Bituminous—The situation does not change much. Shippers are not pleased with the ordering of coal out of this territory to more distant points, especially when the Ohio coal that used to be sold here liberally is cut out entirely and no Pittsburgh coal may come here till a certain amount—1600 cars a day—is shipped to the lakes.

The practice of selling at mine prices grows, for the shipper is not always sure that he has all the items in at any time. Quotations generally made for Buffalo are $4.65 for thin-vein Allegheny Valley, all sizes: $4.45 for Pittsburgh lump, $4.20 for mine-run or slack, and $5.85 for smithing or smokeless. All prices are f.o.b. Buffalo, net tons.

The Canadian supply is still in excess of our own, and efforts are being made to divert the coal to points farther east. Buffalo and New York State are fairly easy as to supply, though shippers do not understand how the supply keeps up, for they were of the opinion some time ago that the consumption exceeded the shipments.

Anthracite—The Fuel Administration has allotted to Buffalo 750,000 tons as the amount of this coal which can be spared. The city will be disappointed, as it had asked for 900,000 tons and hoped to get at least 800,000. Still the present allotment is considerably more than has ever been used and it may answer. It all depends on the supply of natural gas, which cannot be foreseen.

The anthracite coming this way is still quite under the average, both for home use and for shipment west. The Lake shipments are possibly adequate to the restricted territory to be covered, but are not up to average, being for the week 97,200 tons, of which 43,600 tons cleared for Duluth and Superior (consignee's option), 32,300 tons for Milwaukee, 16,900 tons for Chicago, 3300 tons for Manitowoc

and 1100 tons for Marinette. Freight rates remain at 48c. to Duluth, 50c. to Manitowoc, 55c. to Milwaukee, 60-65c. to Chicago and $1 to Marinette.

CLEVELAND

Definite orders have been issued to coal operators not to make further shipments to industrial consumers known to have fair-sized stock piles on hand. Circulars listing concerns able to run until Oct. 1 on their present stocks are being issued. The lake trade continues to fall behind the schedule, and it is feared that the end of August will see the Northwest with more than 2,000,000 fewer tons of bituminous on the docks than was planned. To provide larger tonnages for the Northwest, retail dealers here are being cut to 15 and 20 per cent. of the requirements.

Bituminous—The outlook both as regards industrial and domestic trade has taken a decided slump in the past week. Circulars are being issued by D. F. Hurd, regional director for the United States Fuel Administration, bearing the names of industrial concerns known to have ample stocks on hand. In some instances operators are directed not to ship certain concerns any more coal until after Oct. 1—in a few instances shipments have been cut off only until Sept. 10.

Investigators for the administration are said to have gone into the yards of practically every concern in Cleveland and northern Ohio and photographed the stock piles. One large steel works in Cleveland is said to have between 180,000 and 190,000 tons of bituminous on hand, a 60-day supply at the least. Another northern Ohio iron and steel interest is said to have been found with more than 300,000 tons of bituminous stored. These instances have led the administration to feel that concerns should be compelled to use their stock piles in order to permit a greater diversion of coal to the Northwest while navigation on the Great Lakes is still possible.

Domestic users are informed that once the lake season ends their supplies will become adequate. One result of this situation has been to augment the domestic demand for coke. Complaints against the car shortage on the Pennsylvania R. R. in the No. 8 district have resulted in the arrival of a fuel administration investigator here. Car supply on the Pennsylvania for the first 10 days of August was only 53 per cent. of normal. The road, it has been ascertained, has been according mines shipping railroad fuel a 100 per cent. supply, while other mines were forced to take the leavings. Pennsylvania officials here claim ignorance of any order that car supply is to be distributed evenly, whether or not the mine is putting out railroad fuel, and Pennsylvania officials at Pittsburgh will be called upon to explain, it is said. Considerable complaint is arising, too, in regard to irregular shipments.

Many concerns report they get no cars one day and twice the normal number the next. As a result, the unloading force is disrupted, and much demurrage must be paid. This tends to decrease car efficiency, which is an even more serious condition. According to the report of the secretary of the Pittsburgh Vein Association of Ohio, operators who belong to the association shipped 6277 cars in the week ended Aug. 7, of which 3617 went to the lake trade, 1235 to railroads, 1062 to Ohio, 261 to Michigan and Indiana and 102 to Canada. The 3617 carloads that went to the lake trade are little more than half of the 7200 cars required each week under the order calling for 1200 cars a day from the Pittsburgh district for the Northwest. Car supply has been good on every road except the Pennsylvania. Power supplies are failing mines in southern Ohio and serious trouble is feared. The corporation that furnishes electricity to many of the mines in the No. 8 district is said to be encountering difficulties. The shipments for the week ended Aug. 7 were made as follows: Baltimore & Ohio, 3044 cars; Pennsylvania, 1621; Wheeling & Lake Erie, 1474, and New York Central, 138.

Lake Trade—Shipments of bituminous grow more and more disappointing. Many operators fear the Northwest will not get over 25,000,000 tons, instead of the 28,000,000 aimed at. The first 11 days of August saw lake shipments of bituminous—exclusive of vessel fuel—only 1,535,996 tons. The Fuel Administration's schedule for August calls for 4,900,000 tons. July closed 1,000,000 tons behind, and it appears that August will add about 1,250,000 tons to this deficit. For the week ended Aug. 17 the estimate of shipments to the Northwest is 1,020,000 tons. The Pittsburgh district has not responded to the 1600-cars-a-day order by far.

DETROIT

Shortage of domestic coal supply remains an alarming factor of the market. Fuel Administration affords little relief. Lake movement gains.

Bituminous—Facing a contingency which may lead to serious hindering of production on war contracts by departure of workers from Detroit, local coal jobbers and representatives of large industrial plants are endeavoring—so far with little success—to increase the present movement of domestic coal into the city and obtain an addition to the inadequate allotment of 601,000 tons of anthracite allowed Detroit.

Headed by J. J. Crowley, president of the Detroit Board of Commerce, and accompanied by W. K. Prudden, Michigan Fuel Administrator, a committee of Detroit manufacturers representing concerns engaged on large contracts for the Government, spent most of last week in Washington appealing to the Fuel Administration, the War Industries Board and the Director of Railroads for action to relieve the situation.

The committee appears to have made little progress beyond receiving a promise from the Fuel Administration that a campaign would be opened at once to increase the movement to Detroit of bituminous coal suitable for domestic use. It was informed no addition to the city's allotment of anthracite could be made.

Bituminous coal now coming into Detroit in fair volume, consists for the greater part of mine-run, which is not adapted to use in the hot-air furnace heating plants and base-burner stoves, which predominate in the homes of the city. While the present supply of bituminous provides adequately for present needs of steam plants, little surplus is available for reserves.

Anthracite—No improvement in movement of anthracite has developed. Shipments received on some days fall below 20 cars, while the average is probably below 30 cars daily for the month. Manufacturers say many of their employees will go to cities where they can be assured fuel for winter needs unless the city's allotment of anthracite is increased and a larger movement stimulated.

Lake Trade—Coal is moving rather more freely to lake loading docks and the shipments to ports at the head of the lakes have been attaining a higher volume in August than in July, though many carriers are still making the upbound trip without cargo. Shipments have not yet reached the magnitude necessary to realize the shippers' program of 4,900,000 tons for the month.

COLUMBUS

The lake trade is now the principal activity in the coal industry. Some coal is being diverted for domestic and steam purposes, but the amount is not large. Production is fairly good.

The principal feature of the coal trade in Ohio, is the activity in the lake traffic. Under orders from the Federal Fuel Administration a large tonnage is being rushed to the Northwest and every effort is being made to fill the requirements in that section earlier than usual. It is hoped that the requiremnets can be filled by Oct. 1 after which the product of Ohio and West Virginia mines can be diverted to domestic and steam uses. The vessel movement is active, and little time is lost in handling either coal or ore. Reports show that the coal is being moved off the docks of the upper ports, thus avoiding congestion.

The steam trade is rather quiet, although a certain amount of screenings is being diverted to steam business, which helps to relieve the situation. Most of the larger steam users had succeeded in laying in a supply of coal to last for some time and thus are not suffering. Smaller steam users have sufficient fuel for the present. Most of the public service institutions have made arrangements for their coal supply.

The domestic trade is also quiet, although dealers are still busy making deliveries. Surplus stocks are rapidly being depleted. Practically no Pocahontas is now available and only a limited amount of West Virginia grades is arriving. In fact it is only the smaller mines that have no lake connections that are supplying the domestic trade. Retail prices are firm at the levels which have prevailed for some time. Dealers are beginning to get anxious and are making inquiries if the priority order may soon be modified.

Production has been increased slightly with a better car supply and more plentiful labor. Patriotic meetings held in many mining sections are having their effect in increasing the output. Lack of motive power on some of the railroads caused a temporary car shortage, but steps are being taken to relieve that situation. On the whole the output has been between 75 and 85 per cent. in all of the producing fields of the state.

Prices on short tons f.o.b. mines are as follows:

	Hocking Thin Vein	Hocking Thick Vein	Pomeroy	Eastern Ohio
Sized grades....	$3.05	$2.80	$3.05	$2.60
Mine-run.....	2.80	2.55	2.80	2.35
Screenings...	2.45	2.30	2.45	2.10

CINCINNATI

Continued steady and heavy demand for coal of all sorts is reported, with good conditions in all near-by fields, indicated by record-breaking loadings last month.

While in some quarters pessimism is felt and expressed over the local fuel situation, especially in view of the belief that all West Virginia coal may be diverted eastward in order to satisfy the deficiency in receipts in that section, the general situation is all that could be asked, everything considered. Demand from all quarters remains heavy, and shipments are going forward to the Lakes in large volume. Domestic consumers in this section are still in the market for their winter requirements, and dealers are insistent, in consequence, in their demand for fuel with which to take care of their customers. Considerable receipts by the river have helped out city dealers, but those in the country and near-by towns are finding some difficulty in securing coal. The same is true to a considerable extent of large industrial consumers, as to fuel storage, although so far no complaint has been heard on the score of current supplies. It is generally realized that it is the supply of coal for industrial purposes next winter which will furnish the principal difficulty of the fuel authorities, which is one reason why every effort is being made to get all other demands out of the way before winter comes, in order that the entire available supply may then be devoted to the needs of industrial consumers.

With the bulk of domestic consumption taken care of by unprecedentedly early and complete summer storage, and with the North and the Northwest well cared for by the present heavy movement of coal both by rail and the lakes, it is felt that the entire Middle West, including this city and its immediate vicinity, will face the winter season in much better shape than was the case last year, and with the reasonable expectation that the winter will not be anything like as severe as last winter.

LOUISVILLE

Production for eastern and western Kentucky field about the same, with labor still scarce and cars hard to obtain. Retailers are beginning to catch up on domestic stocking and are offering two-day deliveries at the present time. Steam demand continues fair.

The labor situation in the Kentucky fields has been somewhat better during the past two weeks, due to the exceedingly hot weather, the fact that crops are made, and that men who have been farming are glad to get back to the cooler mines. Retailers have had much trouble in keeping men and teams going during the hot weather, labor refusing to work above ground. However, this same weather has resulted in a letting up of the domestic stocking demand, as no one thinks much of cold weather with the thermometer around the century mark, as has been the case during the greater part of August. Mines expect to start losing labor to the agricultural demand in a few weeks, especially in western Kentucky, where much negro labor will start picking cotton.

In eastern Kentucky many of the wagon mines are now using boxcars for loading and are getting out a much better volume of coal, some of which is reaching the local points, but much of which is being bought up by jobbers and large miners for outside points.

BIRMINGHAM

Local market active, with steam demand apparently a little easier. Domestic trade stiff. Production off from the high record of recent date. Car shortage being felt along with failure of miners to work regularly.

Inquiries for steam are good in this market, the tonnage desired being in excess of that available by a large margin, but reports indicate that consumers are evidently in some better shape of late, as they are not pressing their demands quite so insistently as heretofore. The extremely hot weather of the past week has not weakened the ardor of the domestic user to provide a supply for the wintry blasts to come, and trade is strong in both wholesale and retail circles. More coal was stored, according to official figures, during

July than in any previous month this season.

Alabama coal men are expecting a new schedule of prices from the fuel administrator in the near future, but no intimation has been given as to changes or adjustments to be made other than that there will be a reclassification of the mines to some extent. It appears certain that some more repressive measures will have to be adopted by the fuel administration than those now in vogue to enforce better working schedules by mine workers if coal production is to be materially increased and maintained on anything approaching a maximum capacity in this district. Men lay out from work in large numbers regularly and also fail to work full shifts in many instances. Shortage of cars has crippled production to some extent in the past week or so, most all lines being short of equipment.

Coke

CONNELLSVILLE

Fuel Administration allocations. Market transactions in foundry coke. More by-product and less beehive coke.

The Fuel Administration continues to allocate furnace coke orders to such an extent that practically no offerings come upon the market. A close watch is kept upon the situation and cases of furnaces stocking coke do not as a rule continue long until the operator is given an allocation to snip the surplus coke elsewhere. Of ordinary open market transactions there are practically none in the case of furnace coke. Foundry coke, on the other hand, continues to be offered in considerable volume. On the whole foundry coke shipments are probably well above normal. The operators have plenty of 72-hour coke and it pays to ship the coke for foundry use as long as it can be sold. Frequently a brokerage is paid by the operator. Many of the foundries are no doubt stocking coke, but the total taken out of the situation is not large, as foundry coke consumption is vastly less than furnace coke consumption.

The Youngstown Sheet and Tube Co. has practically completed putting in 51 of its new byproduct ovens, with the second 51 to follow in a few weeks. Unlike the starting of the Steel Corporation's new plants at Cleveland, Lorain and Clairton, the additional byproduct production at Youngstown directly releases Connellsville coke, which as released goes to other consumers. The contracts were closed about three months ago, shipments to begin upon the completion of the new Youngstown ovens and to run to the end of the year. An interesting question is how much the starting of byproduct ovens by the Steel Corporation will reduce its coke production in the Connellsville region. Unless the corporation has been short of coke it could correspondingly decrease its Connellsville production, unless it should sell the coke released, while on the other hand, it might not be able to provide the coal for the new byproduct operations except by decreasing beehive operations. The Cleveland and Lorain plants do not necessarily use Connellsville coal but would use it if no other coal could be had. The Clairton operation was designed to use Connellsville coal exclusively, but to be shipped by water, and for the purpose some of the river mines were enlarged. While one comparison does not prove the case it is an interesting fact that there has been a decrease in Connellsville output which bears a striking resemblance to the new byproduct capacity put in operation.

The "Courier" reported maximum production by furnace ovens in the Connellsville and lower Connellsville region at 210,760 tons in the week ended July 13 and at 177,800 tons in the week ended Aug. 10, a decrease of 32,960 tons. At the same time the merchant oven production only changed from 142,710 tons to 141,210 tons, a decrease of 1500 tons. This would strongly suggest that some special influence was felt, neither car shortage nor labor shortage, as such influences would have affected merchant ovens the same as furnace ovens. The new byproduct ovens the Steel Corporation has lately put in are 180 ovens at Cleveland, which made a little coke late in May; 104 ovens at Lorain, very recently, with 104 ovens more due in about 30 days; and 128 ovens at Clairton, with four similar batteries due at intervals during the remainder of the year. The ovens started total 412, and while nominal ratings are higher, such ovens can generally be counted on for about 4200 tons a year per oven, or about 80 tons a week, so that their output is precisely 80 tons each, 32,960 tons weekly, and the decrease reported was precisely that, down to the last ton.

Owing to the activity of the Fuel Administration the furnace coke market is practically closed, but allocations go at the set price of $6. Foundry coke sells at the $7 set price, sometimes with a brokerage allowed by the operator, and crushed, over ¾-in., remains at $7.30, all prices being per net ton at ovens. Screenings from old dumps when well prepared and over ¾ in. bring $6.50 in the open market.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Aug. 10 at 319,010 tons, a decrease of 21,970 tons.

Buffalo—The supply of coke is scant, but the local furnaces manage to get what they must have. So far the Government authorities have not thought it necessary to make any arbitrary distribution rules in the coke trade and are not commandeering it from this smelting center, but none of it is coming into the hands of jobbers, who try to content themselves with a moderate amount of breeze coke from the local by-product ovens, selling it sometimes for less than the Government price, which is $4.34 at the ovens. Iron ore receipts for the week were 330,690 gross tons, a large amount.

Middle Western

MILWAUKEE

Coal supply coming forward satisfactorily. Dealers looking for an advance in soft coal soon.

The coal supply for the Milwaukee district is coming on apace, and unless for some unforeseen reason there should be a let-up in the movement by lake, the close of navigation will find the full allotment of anthracite and bituminous coal on the docks and in process of transshipment. A close rein is kept both on the movement to interior points and on the supply to city consumers, in the interest of an equitable distribution and to avoid a repetition of some of the experiences of last winter.

Some uneasiness was caused throughout Wisconsin by the action of Federal Fuel Administrator Garfield restricting the consumption of soft coal in Illinois, but State Fuel Administrator Fitzgerald hastened to assure manufacturers that there was no danger that a similar order would be issued in regard to Wisconsin. Illinois is a soft coal consuming state, and the cheapness of this class of fuel in the past has engendered wasteful methods on the part of power plants and householders which the fuel administration now desires to rectify.

Receipts for August up to the time of making this report aggregate 26,786 tons of hard and 306,817 tons of bituminous, making the record up to that time since the opening of navigation on May 1, when the docks were absolutely cleaned up, 272,470 tons of anthracite and 1,685,169 tons of bituminous. During the months of May, June and July rail receipts amounted to 454 tons of anthracite and 60,230 tons of bituminous, against 288 tons of the former and 272,109 tons of the latter in 1917.

ST. LOUIS

An unusually quiet market on everything, with steam sizes heavy. Warm weather has depressing effect. Labor shortage severe from the mines to retail delivery. Water shortage continues. Car supply poor. Transportation continues bad.

The local market is an unusually quiet one. The extremely warm weather of the past couple of weeks had a serious effect in the retail end of the coal business, and many coal men have found themselves with half of their equipment idle on account of their men quitting for easier tasks.

In a general way, however, the retail business is easing up, excepting on Carterville coal. The domestic trade is practically taken care of on Standard sizes, there is a little Mt. Olive unfilled, and a considerable tonnage of Carterville.

Byproduct coke is hard to get and dealers are behind on that, but gas house coke is pretty well up. Figures compiled by the St. Louis Fuel Committee show that St. Louis is unquestionably the best situated city in the country today in the matter of retail storage coal, and perhaps worst off in the matter of steam storage.

Reports from the Carterville field the past week are depressing. In addition to the water shortage, which has been affecting all mines, the power furnished by the Public Service Co. in southern Illinois is permitting the mines to work about 2½ days a week. A meeting of the operators in Chicago this week was held for the purpose of taking some action relative to bringing in Keokuk power through the St. Louis gateway, and this will likely be done. It is understood that this matter has been taken up with Washington and the complaint was made that mines are forced to close daily, in periods from 10 min. to 5 hours, and in many instances the largest mines in the field have been closed for 2 or 3 days at a time.

The car shortage the present week is unusually severe, and on the Iron Mountain for four days straight there was no equipment at some mines. The movement on this road is exceptionally bad, and the Illinois Central fares but a little better.

Labor conditions in this field seem to grow worse, and it is evident that the Government must in the very near future take some steps to keep intact the mining organizations if the operators are expected to keep up anywhere near the tonnage demanded of them.

Similar conditions exist in the Duquoin field. The railroads still continue to take heavily in railroad fuel from both of those fields, in spite of all that has been said and the pleas and the protest from the general public and from those interested in seeing that this quality of coal goes where it is best suited.

The Mt. Olive field has a fairly good car supply and labor supply that is not bad and a tonnage produced that is about equal to the demand. It is the one field in the state where there seem to be no troubles that cannot be easily overcome.

The Standard field presents the same old trouble of having an overproduction of either one or the other grades. At the present time there is an overproduction of screenings and no place to move them, and there is an abundance of lump. The screening movement to Chicago is fairly good and all surplus lump and egg is going to Michigan. If it were not for this the Standard market would be glutted and mines would be idle. These prices are off, screenings being sold as low as $1.55 and $1.60, and lump about $2.35 to $2.40 for 2 in., while the 6 in. lump and egg hold up to $2.55. The car supply in this field is bad, transportation is slow, and car distribution on the Illinois Central still continues bad.

There is a water shortage here that is affecting many of the mines and some of the mines are almost down to one-fourth of their former tonnage on account of labor. In view of the fact that there is a surplus of screenings, which is used by the Union Electric Light and Power Co., the lightless night order is in effect here and is being rigidly enforced. On the surface this appears to be a farce, for unless these screenings are consumed in the home market they remain on track at the mine and prevent work, and their quality is such that they will not move it to the far off markets. The same thing applies to the skip and stop proposition for the street cars. The general public for the first time in many years is becoming somewhat vexed at local conditions. With an abundance of this steam coal, to such an extent that the railroads are blocked and the mines are almost idle on account of this surplus, St. Louis is being deprived of some of its common rights because the eastern part of the country is short of coal and the quality of the coal here does not justify its transportation east.

The Board of Education has announced that 63,000 tons of coal have been stored for the Public Schools, and its consumption is estimated at 70,000 for the 142 school buildings. Last winter St. Louis was the only large city that did not have to close its schools. There are no eastern coals coming in and a very light tonnage of Arkansas.

The circular prices for Illinois coals here are:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump...	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg..	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut..	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut....	2.55@2.70	2.55@2.70	.....

Washed:			
No. 1.....	2.75@2.90	2.75@2.90	.....
No. 2.....	2.75@2.90	2.75@2.90	.....
No. 3.....	2.55@2.75	2.55@2.75	.....
No. 4.....	2.55@2.75	2.55@2.75	.....
No. 5.....	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olice fields, 95c.

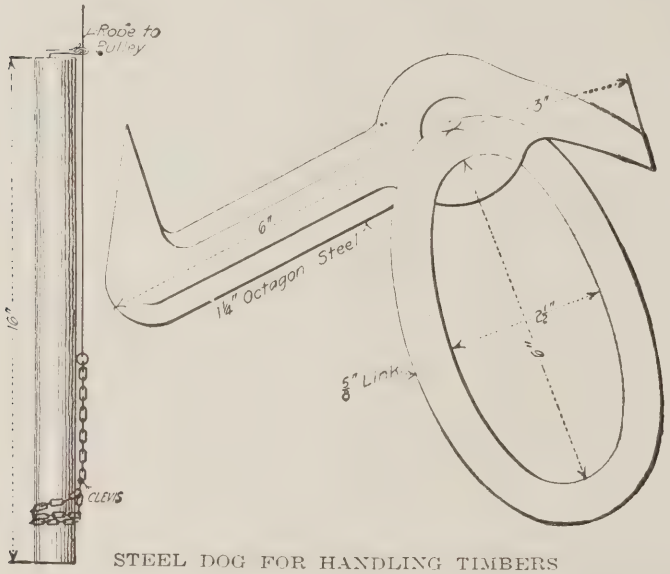
COAL AGE

Volume 14 New York, August 29, 1918 Number 9

The Lucky Thirteen

Written Expressly for Coal Age
By RUFUS T. STROHM

Mining figures sure were checkered,
Running medium to low,
Never coming near a record
Till about a month ago,
When the output curve went crawling
To a sharp and dizzy peak,
For the mining men were hauling
Thirteen million tons a week.



Then there came the news exciting
Of the scrap at La Chapelle,
Where our doughboys, keen for fighting,
Gave the storm troops merry hell;
And they'll keep the Fritzies going
In a scared and frazzled streak
If the mines will keep on showing
Thirteen million tons a week.

That's the figure that we're needing
If we'd keep munition plants,
Factories and shipyards speeding
To supply the boys in France;
For they'll win this bloody duel
With the Kaiser and his clique,
But we've got to have the fuel—
Thirteen million tons a week!

IDEAS AND SUGGESTIONS

Dog for Lowering Mine Timbers

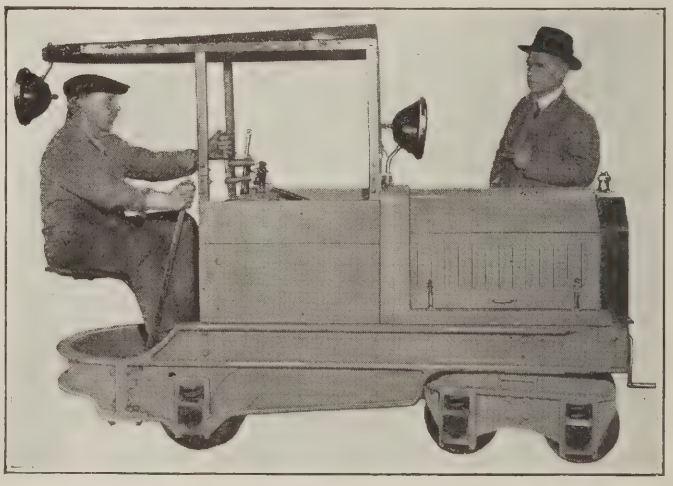
Timbers when being lowered or hoisted occasionally get away, even when a chain is used to grip the piece, says the *Engineering and Mining Journal.* This is especially true if the timbers are icy or wet. At the Hecla mine at Burke, Idaho, much heavy round timber has to be either lowered or hoisted. The caps used in the timbering are green timbers of an average

STEEL DOG FOR HANDLING TIMBERS

diameter of 14 in. They run from 7 to 16 ft. long. The posts are about 8 ft. long and 10 in. in diameter. Yet these heavy timbers are handled safely and easily by the use of dogs, chains and wire rope, the motive power being an air hoist.

The chain is attached to the end of the cable. Instead of having a ring at the end, this chain, which is longer than usual, has a strong clevis. When timber is being hoisted the chain is wrapped round the stick and fastened to itself by means of this clevis. When timbers are being lowered the clevis is used as a means of fastening a ring to the chain, this ring having several timber dogs which are themselves secured by short chains. In lowering timbers, reliance is placed entirely upon the dogs, several being sunk into the stick if it is large.

The timber dog illustrated above is made of 1¼-in. steel, and one end is turned up and pointed after the usual manner. The other end is bent down. When the workman desires to remove the point of the dog from the timber he hits the dog on this downward bend and the dog is released.



About two-thirds of the way from the point of the dog the drill steel is flattened and a hole about 1 in. in diameter is punched through it. A long narrow link made of ⅝-in. steel and large enough to slip easily back and forth over the rope and chain is then put through and welded.

In hoisting timber, the dog is fastened loosely to the cable by means of this link. First the chain is wrapped several times around the timber near the bottom and fastened to itself by the clevis. Then the dog is slipped up along the cable until it can be sunk into the top end of the stick. When the top of the timber has been hoisted level with the landing floor in a stope, a picaroon is applied and the dog at the top knocked loose. Then, as the timber is hoisted further, the top end skids out on the floor, and the stick is guided by means of the picaroon to the place where it is to be used.

In lowering the timbers, a ring to which four dogs are fastened by short chains is used. If the timber to be lowered happens to be large, it is lowered singly and with three dogs. If the timbers are small, several are lowered at one time, a dog being sunk into each near the top. Whether the timbers are lowered singly or several at the same time, they are fastened only at the top, so that as soon as the floor is reached they can be landed easily by the use of a picaroon applied at the lower end, the workman walking out into the stope with the timber. Thus when lowering as well as hoisting timber, the bulk of the weight is kept on the cable, and the work of landing a heavy piece is reduced to a minimum.

This Ford Handles Mine Cars

The illustration shows one more use to which the universal Ford motor has been put and its adaptability for underground haulage problems. The locomotive was built by the McFarlane-Eggers Machinery Co., of Denver, and is now operating in the Royal Flush mines, of

FORD MOTOR USED FOR HAULING

Columbine, Colo. Details of the body are apparent from the illustration. The locomotive has a four-wheel fore truck which is pivoted to the frame. The frame consists of three iron castings, on which the well-known bonnet and a wooden cab and seat have been mounted.

The locomotive shown operates over an 18-in. gage track and will negotiate an 8-ft. radius curve. It is 30

in. wide, 7½ ft. long and weighs 2500 lb.; and the overall height at the cab is only 4 ft. The locomotive travels at a speed of 10 miles an hour and will draw from six to eight one-ton cars. This adaptation of the Ford motor will undoubtedly solve many problems in small outlying districts heretofore handicapped by the necessity of choosing between costly hand tramming over long distances or expensive and unwarranted haulage installations.

An Old Man Fastening

By J. A. Lucas
Ozone Park, N. Y.

A simple method of fastening an old man to large cylinders or boilers, where no holes for clamping are available, is shown in Fig. 1. *A* represents a boiler shell or tank, to which is attached an angle frame or knee *B*, carrying the angle piece *C* (which may be adjusted for vertical height on *B* by means of the bolt shown) forming a fulcrum for the feed sleeve *D*. The chain *E* passes around to secure the angle frame *B* to it. It is tightened by means of the device shown in Figs. 2 and 3. In using the clamping device shown in Fig. 2 the chain has to go around the cylinder only once. Its operation is self-explanatory. The clamping device shown in Fig. 3 necessitates the chain to pass around twice; in use the loose chain is placed in the yoke *F*, which in turn is slipped on the square-head screw of the jack *G*. The chain is then tightened by means of the jack. Such devices as the one here described permit the use of the old man upon surfaces where the ordinary means of attachment, such as bolts and clamps, cannot be employed.

Electric Locomotives and Trucks

The electric locomotive has already made a well-established place for itself in the coal-mining industry. It appears in two general forms—the trolley locomotive and the storage battery machine. Each of these has its place of peculiar advantage, and the manufacturers of electric locomotives have a fund of interesting ideas and data on tap as to where and how one may give the best service, and where the other may be more satisfactory.

Broadly speaking the question of selection hinges upon local conditions and requirements. The generally accepted logic is that the trolley locomotive is more economical in power consumption while the battery locomotive is adaptable to service where it is not practical to handle a trolley machine, especially in new openings and drifts before the work has progressed far enough to warrant the equipment of a trolley line. Also it is often argued that the service rendered in what might be termed pioneer progress of new work by the battery locomotive outweighs any disadvantage in power cost.

The electric locomotive of the battery type, like its cousin the electric truck, has had the experience of being viewed with favor, then seeing the favor suddenly swing around and center upon the remarkable and startling progress of the gasoline motor. This applies both to commercial trucking and pleasure vehicles. Now we are seemingly swinging around in the circle to where favorable attention is focusing once more upon the electric storage battery, both for locomotive work and for trucks.

Taking into due consideration the fluctuations in the value of coal at the mines, experience has demonstrated that electricity can be produced in proper power plants at the coal mines in commercial quantity more economically than by waterfalls. All of this leads in a roundabout way to the subject of electric locomotives and trucks. Coal producers not only quite commonly have a direct interest in the operation of some electric locomotives in their own plants, but they have a broad interest in the development of power units generally for the production of electricity. To state it another way, a wider and more extensive use of electric trucks and pleasure cars would mean quite a considerable increase over the amount of fuel that is now being consumed in the production of electricity for power and other industrial purposes.

Moreover, it is interesting to note that considerable progress in the way of improvements have been made in electric storage batteries. Perhaps it would be too much to say that we are on the eve of a return of wide favor to electric cars and trucks. At the same time, however, we know that gasoline is comparatively high priced and the adaptation of the gasoline engine to perform individual and home requirements has so extended the demand for gasoline that already some concern is manifested about the future supply.

Longwall Mining at La Salle, Illinois

By GEORGE W. HARRIS
Editorial Staff, "Coal Age"

THE La Salle mining field of Illinois is full of association and interest to many coal men, both operators and miners. The name La Salle will catch the eye of coal men the country over, for in this old longwall region many received their training. Some of the old-timers still remain in positions of trust—both as officials and as miners of coal. It was at Spring Valley, in this field, that John Mitchell spent his early days.

Among the prominent mining companies in the La Salle field is the La Salle County Carbon Coal Co., with four plants—La Salle, at the town of the same name; Union, at Peru; No. 1, at Johnsville, and No. 5 at Cedar Point. This company operates the oldest mine and the newest mine in this longwall field. The La Salle mine was opened up by a shaft in 1856, when the No. 5 seam was worked by room-and-pillar until 1880. At the later date the shaft was sunk to the No. 2 seam, which has been continuously worked by longwall. It has the distinction of being the first mine in the district to be worked by longwall.

In 1868 the No. 1 mine of the La Salle company was opened up at Johnsville, which is two miles south of La Salle. The Union mine at Peru was started in 1874, and the No. 5 plant was developed in 1906 at Cedar Point, which is five miles southwest of La Salle. This latter mine was the latest longwall operation to be developed in the field. These plants are near the Illinois River, on the Rock Island R.R., and in the northern central part of the state. In fact, the region constitutes the northern limit of the Illinois coal fields. The La Salle anticlinal is to the east of the properties of the La Salle County Carbon Coal Company.

The coal seams are somewhat disturbed, as the pitch of the beds is about 40 to 50 deg. at the anticlinal instead of practically flat, as is the case elsewhere. Coal is disposed to be rather shelly where disturbed, and the top also changes. At this point the anticlinal tips to the west. The modification in the method of mining on this heavy pitch is described in the June 17, 1916, issue of *Coal Age*, under the title of "Steep-Seam Longwall in Illinois," by C. A. Herbert.

Ideal Longwall Conditions

The No. 2 seam worked at all the mines of the La Salle company averages about 40 in. in thickness. It is uniform throughout the district and lies at a depth of 350 to 550 ft. below the surface. The roof is a grey shale, or soapstone; the floor is a fireclay, several feet in thickness, below which is sandstone. The immediate roof and floor furnish abundant material for packwalls. Practically no gas or water are found in these mines. In fact, water is piped down the La Salle shaft for use in watering the entries and haulageways, which otherwise would be dry and dusty.

Until a few years ago all the mines in the first district were pick mines. The La Salle company was a pioneer as regards the use of electricity underground. Three or four years ago the first electric hoist in the region was installed at the Union mine. It was also one of the first longwall mines in the field to put in trolley haulage. Of the four mines of this company, La Salle and Union mine coal by machines. At the time of their installation there was considerable opposition to their use and great adverse comment to this change in the generally accepted method of mining in the locality.

A few facts of general interest might be noted about each of the four plants of the La Salle County Carbon Coal Co. The history of the La Salle mine has been an eventful one. The surface works burned down three times at this operation. There are three Sullivan longwall mining machines and one 5-ton Goodman electric locomotive at the La Salle mine. The gathering of coal is done by ten mules. The capacity of the plant is about 700 tons daily, but 400 tons is the present output. There are 142 inside men at the La Salle mine, 106 being miners or loaders.

Machine Longwall Mining

At the Union colliery there are five Sullivan longwall mining machines and one 5-ton Goodman electric locomotive. Gathering is done by mules. The success of the method and the type of mining machine used is attested by the fact that additional machines are to be installed at this plant. There are 171 inside men employed here. The capacity of the Union mine is the same as that at the La Salle operation.

No. 1 and No. 5 are pick mines; the former employs 207 men and has a capacity of 950 tons daily (650 at present); the latter has 252 inside men, with a present capacity of 800 tons (the mine would be capable of producing 2500 tons daily if labor and cars were available). At No. 1 colliery the haulage is done by two Goodman electric locomotives; and mining machines will be installed in the fall. All the mines are working at only about 60 per cent. of their rated capacity. An article on "Longwall Mining in Northern Illinois," by E. T. Dent, appeared in the July 17, 1917, issue of *Coal Age*, in which was illustrated the No. 5 tipple of the La Salle company. It is an up-to-date steel structure.

Electric power for use at the plants of the La Salle company is purchased of the Illinois Traction System, current being delivered at 2200 volts alternating current. For mining machines, alternating current of 240 volts is used, and 250 volts direct current for haulage. At the Union mine there is a motor set underground to produce direct current for haulage. At the La Salle mine the motor generator-set is on the surface. At this latter plant mining machines using direct current were installed at first, these being changed later for those of the alternating-current type.

A "canny" Scot, who had spent a lifetime in longwall mines in his native country and in this, the land of his adoption, was asked what are ideal longwall conditions. He replied: One foot or so of fireclay under the coal; 3 to 3½ ft. of coal—better to be fairly strong; shale or similar material as top rock—furnishing easy brushing and good material for walls. The shale top might be

10 ft. or more thick to advantage. On inquiry as to what should be done in case of a hard sandstone top, he answered: Shoot down the top or get packing material from the bottom. Such conditions are typical of many districts in Scotland, he added. How nearly the ideal longwall conditions noted correspond to those existing in the La Salle region.

The accompanying illustration, Fig. 1, shows actual mining conditions at the La Salle company's No. 5 mine. In all old mines development included a three-compartment shaft; two compartments were used for hoisting and constituted the downcast; the third compartment was boarded off from the others and was the upcast. This method is open to objection as regards efficient ventilation, in that the division board partition seldom remains tight. A more serious objection, in case of a bad accident in the shaft or an explosion in the workings reaching the shaft, is that the ventilation might be destroyed and great difficulty be experienced in restoring it within a reasonable length of time. In modern mines the hoist shaft is the upcast and the second or escape shaft is the downcast. The No. 5 mine of the La Salle company is an example of this latter arrangement. The other three mines are older and have three-compartment shafts.

There are two principal methods of proceeding when the shaft reaches the coal bed which is to be mined; one is to leave a sufficient coal pillar to protect the shaft and the other is to remove all coal and let the packs, or packwalls, settle at once. The advantages of driving narrow work to the boundaries, then starting the face and working back to the shaft, are well known. This method requires considerable deadwork before returns are realized, and necessitates large capitalization. The other method, or longwall advancing, is generally employed, for obvious reasons.

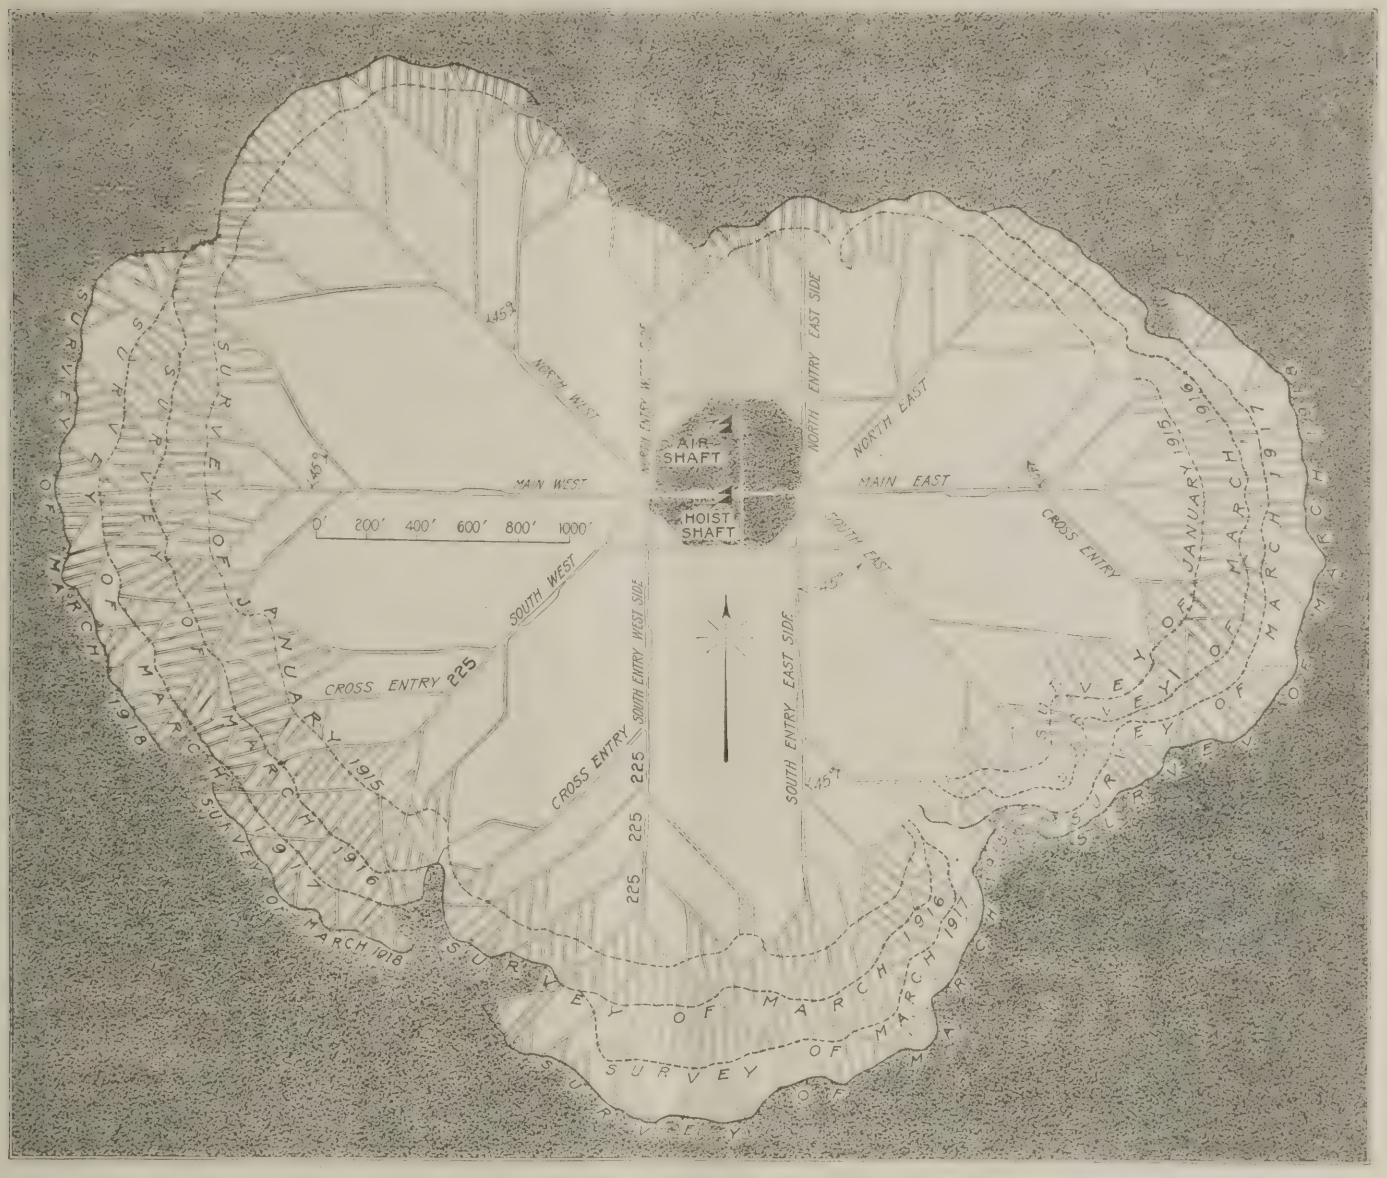

FIG. 1. MAP OF LONGWALL MINE AT PLANT NO. 5 OF LA SALLE COUNTY CARBON COAL CO., NEAR LA SALLE, ILLINOIS

As regards opening up a longwall mine, the shaft may be thrown out of plumb if the right conditions of mining are not carried out, whether with or without coal pillars at the foot of the shaft. When all the coal is removed around the shaft bottom, settlement of packs must be gradual and sudden slipping of large masses of rock be avoided if the shaft is to be kept in alignment. However, when the top rock comes to rest permanently, then the job is finished and the expense and worry about the shaft protection ordinarily are over. The advocates

of this method are willing to take chances of shaft trouble in the beginning in order to have immunity from all such annoyance in the future. The claim is made that with either method of opening the mine the shaft may be endangered at this time. At the escape shaft at No. 1 mine all coal was extracted around the bottom at the beginning.

Other great advantages claimed for removing the coal around the shaft are that the expense of timbering the bottom is reduced and that roof weight begins sooner to ride on the working face. Those operators who leave coal for shaft protection admit these advantages, but claim the great uncertainty of being able to control subsidence, which may seriously affect the shaft as the coal is being removed.

If the coal is to be left in at the shaft bottom, it is necessary to judge about right as to what constitutes sufficient protection for the shaft. The depth of the seam below the surface, the nature of the rock immediately over and under the bed, as well as higher up, are important considerations; also the thickness of the seam and its crushing strength. A number of well

FIG. 2. OFFICES OF LA SALLE COMPANY

known formulas are available for reference as to what size shaft pillar should be left.

It is a matter of record among a number of authorities on this subject that given a shaft 300 ft. deep and a 6-ft. seam, the size of a pillar varies from 70 to 300 ft. square, according to which formula is used. No hard and fast rule can be given for determining the size of the shaft pillar in any particular case. But the rules of those who have carefully investigated the size of pillar required within certain practical limits, and suited to different conditions of roof strata, are useful. Local practice often reflects the experience of years, and it is generally safe to consider such guides in planning new work.

The greatest difficulty in starting longwall operations is in leaving the shaft pillar and establishing the longwall face. A common method in the La Salle field is to drive main entries from the hoisting shaft through the shaft pillar. Then the shaft pillar is usually blocked out by driving entries around it. In many cases these latter entries are driven wide enough to permit of good wooden cogs and packwalls being put in, so that the coal of the shaft pillar may not spall off and the entries be kept open. Great care must be taken in leaving the pillar to pack the ground solid.

The shape of the property to be developed largely determines the layout of a longwall mine. Ordinarily, development proceeds with the shaft pillar as the center of the prospective mine with main entries leading off in eight principal directions, consecutive entries having an angle of 45 deg. between them. From these entries rooms are turned at an angle of 45 deg. and spaced so as to give a distance apart of about 42 ft. at the face. As the distance of the face from the shaft increases, cross-entries are driven from the main entries and new rooms may be opened up from the former. Engineering skill finds an opportunity in longwall mining as well as in room-and-pillar work. This applies to planning a mine and in following up the progress of the working face.

Having blocked out the shaft pillar and laid out the mine for best development, mining is commenced on the approved lines, looking to the establishment of the working face. A critical time in longwall mining occurs when the first roof break takes place, or at the time when it is expected. As in pillar work in room-and-pillar mining, roof pressure is an important consideration. The nature of the top largely influences operations. With a thick sandstone or limestone roof, large openings are frequently made by the removal of pillars without falls of top occurring at first. Sometimes all props in the robbed-out area are removed, and heavy shots are necessary to bring about a good break in the top. Once established, robbing generally proceeds with no unusual difficulties in all well regulated mines.

Contrary to room-and-pillar practice, in longwall mining the roof pressure is essential to break down the coal—roof pressure should be the only permissible explosive in the coal itself at the longwall face. In opening up the longwall mine the first roof break may not occur until the face has advanced 100 ft. or more from the shaft pillar. When the top is moving properly, it bends at the face and settles down on the packwalls and gob (space between the packs); cracks generally appear at regular intervals and parallel with the face. Especially in machine mines a space of about 3 ft. is required at the face in which to operate the mining machines. The top usually cracks at the edge of the coal and often breaks just beyond the props set 3 ft. back. With proper packing the distance between breaks should correspond to the width of the coal brought down.

The longwall face being established, the operations of the mine proceed regularly if the packwalls are kept up in good shape and the face in line. The mine should be so laid out that development is symmetrical, the face forming approximately a circle with the hoisting shaft as the center. Sometimes the face takes the shape of an ellipse rather than a circle. The main entries and branches are projected so as to constitute a comprehensive haulage system as the mine develops. When packwalls are first made they are often spaced 10 to 12 ft. apart, lining the roads, to allow for the bulging when the roof weight settles on them, which causes narrowing of the roadways. The rooms are laid out so as to reach the face practically perpendicularly, and to block it off in about 42 ft. sections. A track is laid to the face of each room. As the rooms reach a length too great for profitable operation, cross-entries are turned off and new rooms are started from these entries—everything

proceeding on the 45-deg. system. It is important to have longwall rooms at right angles to the face, as the top rock settles better and the brushing of the top is easier.

Fortunate is the operator, during these days of the necessity for high production and with scarcity of labor, who has mechanical equipment adapted to his needs. The La Salle company was the first to install mining machines in the northern Illinois longwall field, and plans to add to the number on hand in the near future. The La Salle and Union plants of this company are machine mines and haul coal by motor.

The coal is undercut by Sullivan longwall machines, at the mines noted, to a depth of 4 ft. Each machine covers about 1000 to 1500 ft. of face, and after finishing this cut is moved back to the point of beginning. In some mines each machine continues on around the whole face; this plan avoids moving the machine back again, a loader will use it at the center, opposite a haulageway or room, to make a start on the coal while waiting for the top to work it. After the coal is loaded out props are set 3 ft. from the face and 1 ft. from the last break in the top; rock is then packed in at roadways up to these props. In machine mining the packing is done by day labor; in pick mining the miner contracts to brush the top and build packwalls. In pick mining, at the face the top is brushed 24 in. high, the width of the roadway (as per state contract), so there is about 6 ft. headway at haulageways. Finally, on account of settlement, 2 ft more of top is brushed to secure the necessary height. Usually back-brushing in the entries is sent out of the mine. In machine mining three to four feet of brushing is shot down and put in packwalls. This makes a larger and better pack and does away with back brushing to a large extent.

The best top breaks are about vertical. If the top is

FIG. 3. TIPPLE AT HISTORICAL LA SALLE MINE OF LA SALLE COUNTY CARBON COAL COMPANY

but it is a serious disadvantage when one machine in the lot is held up for one reason or another.

In the La Salle field there are more or less sulphur bands of irregular occurrence throughout the seam, especially in that portion of the bed next to the bottom. When a mining machine strikes a sulphur band, or ball, the bits are quickly incapacitated for further service; the hard sulphur either dulls them or in some cases breaks off the point. For this reason, a machine often undercuts an average of only 10 to 12 ft. of face with one set of bits. A machine gang includes a runner, a bit setter and a timberman. The latter follows the machine and sprags or blocks the coal by placing wedges in the kerf or undercut about every 6 ft. of face.

After the coal is undercut, the loader waits a certain length of time for the coal to break on account of the roof pressure. Meanwhile he snubs the coal or enlarges the kerf, so that the coal may fall better. Otherwise it might drop in a mass. Seldom should powder be used in loosening coal in longwall work. Occasionally not settling right, it is likely to break back at an angle over the coal; the weight then is largely taken off the coal, and it does not work right. For various reasons a portion of a longwall face may be retarded and the regularity of the line of the face be destroyed. Closed places often lead to loss of coal. In longwall work the best results depend on all miners or loaders coming to work regularly, so that one part does not lag behind other sections. Oftentimes two roads come together in such a way that a piece of coal is left between them. In any case where the weight comes on a body of coal insufficient to support it, the coal is crushed and lost. Or, if the top breaks over it, rarely is it recovered. The waste rock should fill the gob (the space between packs) sufficiently to allow the roof to come down gradually without breaking off short at the face or packs, but should not fill the gob so completely that it carries too much of the roof and does not throw enough weight on the face of the coal.

In the case of seams containing much sulphur, trouble

is often caused when coal is left in the gob. The sulphur adds to the danger of fire by spontaneous combustion. A gob fire is principally objectionable on account of its heating the air, and the fumes and smoke drive out the miners in the portion of the mine reached by the affected air current. The longwall mine has every opportunity for efficient ventilation, the air current sweeping along the entire working face where it is most needed. Some air always leaks through old packwalls; the crevices are not visible, but the hissing of air at leaks is sometimes noticeable. The air currents from different splits meet in a number of instances at a point along the face at the end of return airways, but no difficulty is experienced from baffling unless the air current on one side is very much stronger than that on the other. The modern acetylene mine-lamp contributes not only to the purity of the air, but to the safety of the miner as well. There is no smoke to pollute the air and also obscure dangers by an impenetrable cloud. The La Salle company uses a carbide lamp, made by the Shanklin Manufacturing Co., of Springfield, Illinois.

Accompanying this article are two illustrations (Figs. 2 and 3) of the surface plant at the La Salle operation. The general office of the company is shown in Fig. 3. Among the officials of the La Salle County Carbon Coal Co. at La Salle are: C. C. Swift, general manager; Adam Currie, mine superintendent, and J. D. Walsh, top superintendent. *Coal Age* is indebted to the courtesy of these officials for information about their operations.

Raising Two 350-Hp. Boilers

By M. C. Scheble
Sabinas, Coahuila, Mexico

The accompanying photographs show the method recently used for hoisting into position two large Wickes boilers that are being installed to utilize waste heat from 60 beehive coke ovens in northern Mexico.

The boilers are each of 350 hp. and designed for a working pressure of 225 lb. The bare boilers, as shown, are about 35 ft. in length and the drums are 84 in. in diameter. The weight of the boilers, without fittings, is 52,500 lb. each, and this total weight had to be suspended, momentarily, to get the boilers into position to be lowered to the final location.

To handle these boilers a frame was constructed 49 ft. in height. The legs were made of 12x14-in. all-heart timbers with heavy butt splices. The headpiece was made of two 12-in. 40-lb. I-beams.

Two sets of rope blocks were constructed. The upper blocks had six 18-in. sheave wheels and the two lower blocks five similar wheels. Two "snatch blocks" were securely fastened to "deadmen" set in concrete to the rear of the boiler settings, and two snatch blocks were also similarly placed near the edge of the railroad track in front of the boilers.

Three-quarter-inch, 6 x 7 haulage cable was threaded through the blocks and the two ends brought to the railroad track, passed through the snatch blocks there and fastened securely to two 55-ton locomotives. The boilers

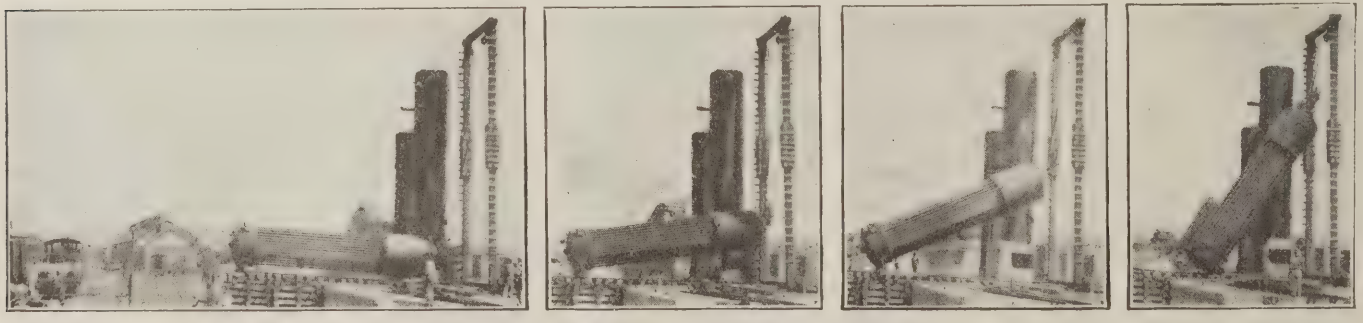

FIG. 5. BOILER IN PLACE ON FOUNDATION

were placed in the position shown in Fig. 1, the lower end being supported on four 56-lb. rails which were well greased.

When all was made ready the two locomotives moved in opposite directions and the boilers were hoisted slowly into position. The whole operation of hoisting the boiler shown in the pictures consumed 1 hour 30 minutes. The other boiler was set in position in 2 hours 20 minutes.

The lower, or rear, end of the boilers was prevented from moving forward too rapidly by means of blocks and cable, the latter being fed out from a small hand winch. The method as used proved safe and successful.

FIGS. 1 TO 4. PROGRESS MADE IN HOISTING BOILER FROM HORIZONTAL TO VERTICAL POSITION

The Coal Problem Under War Conditions*

By H. H. STOEK
Professor of Mining Engineering, University of Illinois

UNDER war conditions the middle man practically has been eliminated and the cost problem has assumed an entirely new aspect. Previously the product supplied a ruinously competitive and glutted market in many cases. Now there is a scramble for fuel in all parts of the country; it is only by the nicest adjustment of conditions affecting production, transportation and distribution of coal that the domestic consumer and essential industry can be supplied. In commenting on this situation, a representative of the Fuel Administration touches on increased production, the cost of coal, better utilization of fuel and the storage of coal. Some pertinent and helpful suggestions are made.

IT IS natural for every one participating in the production of war materials to think that the part of the war game in which he is a direct player is of paramount importance. Hence, the farmer, the gunmaker, the manufacturer of explosives and the railroad man each thinks he is the indispensable one; but, granting full credit to all of these and every other industry, no one can controvert the claim of the coal man that his industry is fundamental to the success of most, if not all of the other war industries. Without coal the railroads could not run, the munition plants would have to stop and the shipyards would go out of business, and no matter how large an army we might be able to raise and train, it would be impossible to equip, maintain and transport it to Europe if the coal supply were cut off.

Germany recognized the importance of coal in her initial drive toward Paris, and by over-running Belgium and northwestern France she not only protected her own coal and iron industry of western and northwestern Germany, but took from France and Belgium their coal resources and added them to the resources of Germany, thus striking a double blow at our allies.

Factors Preventing Maximum Coal Output

A detailed study of the effect of the war on the coal resources of Europe as it affects this country would be of interest, but space will not permit such a discussion in the present paper, which is confined to a few of the problems most closely connected with war conditions. The mines of the country have thus far been able to maintain an output up to the limit that the railroads could transport, and in all of the Government reports giving the reasons for the shortage the principal cause has always been the lack of cars and the lesser causes have been the shortage of labor, strikes and mine disability. In the reports for the week ending Apr. 27, 1918, the production was 74.7 per cent. of the full-time output, giving a deficit of 25.3 per cent. distributed as follows: Car shortage, 14.4; labor shortage and strikes, 4.4; mine disability, 2.8; no market, 1.2; all other causes, 2.5.

This is a creditable showing on the part of the mines up to the present time, but what of the future? The supply of new labor from southeastern Europe has been cut off, and men are being withdrawn from the mines for military service. It is becoming increasingly difficult for the mines to obtain equipment, hence operating conditions cannot improve materially; and this means more concentrated effort on the part of everyone connected with the mines if the output is to be kept up or increased to supply the natural and abnormal demands of war times.

No industry has ever been so completely revolutionized in so short a period of time as has the coal industry during the past year, and, even assuming that all of the changes made and proposed will be ultimately beneficial, no industry of the magnitude of the coal business can so completely readjust itself to new conditions without facing a number of problems that would naturally reduce production, at least temporarily.

Many Problems to Be Considered

Problem No. 1 from the standpoint of the miner and the operator would therefore seem to be to provide an increased production with a probably constantly decreasing labor supply, with material and supplies difficult to obtain and with agencies for distribution entirely different from those under which the industry has been operated for years.

Problem No. 2 might be stated as follows: What does a ton of coal cost? Prior to the war attention was being directed to this matter in various parts of the country by a number of different coal associations in an effort to furnish the Federal Trade Commission with certain information regarding the actual cost of producing coal. Throughout the country an effort was being made to get the detailed costs in a much more comprehensive way than had ever before been done.

Presumably the selling price of a ton of coal bears a fairly definite relation to its cost of production, but at the present time no one knows the exact basis upon which selling prices are determined. The cost of a ton of coal next to the cost of a loaf of bread appeals more definitely to every citizen than any other item of his daily life. Clothes are important and a necessity, but last winter's suit can be brushed up and worn again. Not so with last winter's coal pile; it is not only a definitely diminishing asset, but once gone is a permanently diminished asset which must be replaced by every householder, to some extent at least, no matter what the price may be. The coal bill, like death and taxes, is always with us. The per capita production of coal in the United States at the present time is approximately six tons per person, which means that every person in the United States must lay down at the mine mouth $12 to $18 per annum.

Every citizen is of course indirectly interested in copper and iron, but so indirectly that he does not realize the difference between copper at 15c. and at 35c., or between iron rails at $30 a ton and $90 a ton; but

*Paper read before the Illinois Mining Institute at Peoria, Ill., on May 23, 1918.

the increase in the price of coal to the domestic user of $2 to $3 per ton makes this problem one of very general and vital interest. A definite problem at the present time is therefore to determine what is the actual cost of producing coal and what is a just price for the consumer to pay.

No consumer can rightly object to paying a full, honest price for an article, which price includes a fair profit to the producer, but he has a right to object to overcharge or being made to pay for items in the cost account that do not rightfully belong there. For instance, if a certain retailer bases his profits on a number of bad debts that are excessive and due to his own careless methods of bookkeeping, and not upon a fair average of bad debts that must be included in any business, the purchaser has a right to object to thus being taxed for a part of his neighbor's bill. It is undoubtedly true that the coal producers are entitled to a much better return upon their business than that received prior to the beginning of 1917, but the sky-rocket prices of the first half of 1917 brought their own downfall.

Will Better Understand Production Costs

One definite outcome of the operation of coal mines under war conditions will unquestionably be a better knowledge on the part of the coal men themselves as to what it actually costs to produce coal. Greater publicity also will be given to these costs, and the general public will learn what constitutes a fair price and in this way two very harmful pre-war ideas should be done away with: First, the too prevalent idea of the coal producer and coal dealer that the general public has no right to know what it costs him to do business and that he is at liberty to charge just what he pleases and all that the traffic will bear; and second, the general public should give up the idea that has been all too prevalent that every coal producer and coal dealer is making money at an abnormal rate. The detailed study of costs now being made also means a closer study of ways of operating and an increased efficiency in the operation of mines.

Problem No. 3 may be stated as the better utilization of the coal product of the country. It is difficult for the American people to realize that in a country having practically unlimited coal resources it is necessary for them to be careful in the use of coal. Two years ago, if a person had said that it would be necessary to curtail the output in the ceramic industries and to compel the florists to operate half-time for lack of coal, he would have been laughed at; but these things have happened, and before another winter is over no one can prophesy what may be necessary in the way of suspension in order that the absolutely necessary war industries may be kept going.

The reason for the scarcity is easy to see, and it is an easy matter to blame it on the railroads, but while the railroads may be to blame for not delivering the coal, the user of the coal can not be excused for wasting a large part of the material delivered to him.

David Hyers, a well-known mechanical engineer of New York City, last winter estimated that 117,000,000 tons of coal could be saved by more efficient management of boiler furnaces. In this way a saving of about a billion dollars could be made, or enough to pay the interest on a Liberty Loan several times greater than any yet contemplated. It would require two million freight cars to move the coal that might thus be saved, and by such a saving the difficulty of the railroads might be done away with. The stopping of this waste has become not only an economic necessity, but it is a patriotic duty as well. Not only is the power plant an uneconomic user, but every householder and every form of industry must share the responsibility. So ingrained is the idea in every American that he is at liberty to waste all of the resources of the country that he wishes, that it will take some hard knocks to shake him out of this self-complacent attitude; and it looks very much as if some of these knocks are coming in the near future, unless the same result can be obtained by education, information and voluntary effort.

Problem No. 4 may be stated as the storing of coal for future necessities and the utilization of varieties of coal to which we have been unaccustomed in the past. Whether or not we like the zoning system we have it and must govern ourselves accordingly and in many cases must learn how to use different coal from those grades which we have been accustomed to use for many years. This, of course, does not affect most of the mining regions, but in cities like Chicago it is a material problem; for in that city approximately 100,000 flat buildings have been heated by furnaces designed to use smokeless coals and operated under a smokeless ordinance to which there is a penalty attached for allowing smoke to escape into the air. Suddenly the supply of smokeless coal is shut off, and as the same appliance must be used the fireman must be taught how to burn the new fuel. While this may temporarily cause an inconvenience to people in Chicago, it must ultimately benefit the coal industry of Illinois because it has been demonstrated that Illinois coal can be efficiently burned under city conditions such as prevail in Chicago; and when the people have been accustomed to it and the market firmly established, there will be no excuse to going back to coals produced outside the state.

Question of Gas from Coal

A similar problem is the production of gas from our local coals. This question had been studied carefully for some years prior to the war, and investigations are still under way looking to a more general use of Illinois coal in gas production as well as in coke ovens. This phase of the coal problem will unquestionably be of benefit to the coal industry.

When people become convinced of the fact that they can store Illinois coal in large quantities by properly handling it, they will look upon it as merely a form of insurance and will be perfectly willing to lay up in summer and spring a sufficient quantity to tide them over the congested period in the winter when it is difficult to operate both railroads and mines, and in this way both mines and railroads should be benefited by more regular operation during the summer and spring months. If the following suggestions are observed Illinois coal can be safely stored: 1. It is practicable, advisable and advantageous to store bituminous coal not only during war times but also under normal conditions, either at the mines, near the point where it is to be used or at some intermediate point. It is well to

store coal as near the point of consumption as possible to avoid rehandling. The reasons for storing coal are: (a) To insure the fuel consumer of a supply of coal at all times. (b) To take advantage of lower freight rates, or of lower prices of coal at certain seasons of the year. (c) To permit the railroads to utilize their cars and equipment to the best advantage. (d) To permit the mines to be operated more steadily.

What Coals May Be Stored

As to the kinds and sizes of coal that can be stored: (a) Although it is undoubtedly true that some coals may be stored with greater safety than others, the danger from spontaneous combustion is due more to improper piling of coal than it is to the kind of coal stored. (b) Most varieties of bituminous coal can be stored in the air if of proper size and if free from fine coal and dust. The coal must be so handled that dust and small coal are not produced in excessive amounts during the storing because spontaneous combustion is due mainly to the oxidation of the coal surface. All varieties of bituminous coal can be stored under water, which excludes the air and prevents spontaneous combustion. The danger of spontaneous combustion in storing the coal is very greatly reduced if not entirely eliminated by storing only lump coal from which the dust and fine coal have been removed. Of two coals the least friable should be chosen for storage purposes because less dust and fine coal will be produced in its handling. (c) Fine coal or slack has sometimes been successfully stored (1) by preventing air currents through the coal pile by means of a closely sealed wall built around the pile; (2) by closely packing the fine coal: Such a coal pile must be watched for heating. Piles of slack must be closely watched for rise of temperature and means provided for promptly moving the pile if heating develops. The only absolutely safe way to store slack or fine coal is under water. (3) Many varieties of mine-run coal can not be stored safely because of fine coal and dust mixed with the lumps. (4) Coal exposed to the air for some time may become "seasoned" and thus may be less liable to spontaneous combustion due to the oxidation of the surface of lumps of coal but opinions are by no means unanimous upon this point. (5) It is believed by many that damp coal stored on a damp base is peculiarly liable to spontaneous combustion, but the evidence on this point is by no means conclusive. It is safer not to dampen coal as it is being stored or after it is placed in storage.

3. As to the effect of sulphur on spontaneous combustion: It has been shown by experimentation that the sulphur contained in coal in the form of pyrites is not the chief source of spontaneous combustion, as was formerly supposed; however, the oxidation of the sulphur in the coal may assist in breaking up the lumps of coal and thus increase the amount of fine coal, which is particularly liable to rapid oxidation. Even this latter opinion is not unanimously indorsed. In spite of experimental data showing that sulphur is not the determining element in spontaneous combustion the opinion is widespread that, if possible, it is well to choose a coal with low sulphur content for storage purposes.

4. Regarding the method of piling coal: (a) To prevent spontaneous combustion either coal should be so piled that air can circulate through it freely and thus carry off the heat due to oxidation of the carbon, or else it should be so closely piled that air can not enter the pile at all, and thus the fine coal will not be oxidized. (b) Stratification or segregation of fine and lump coal should be avoided since an open stratum or a chimney of coarse lumps of coal gives a passage for air to enter and come in contact with fine coal and thus oxidizing and starting combustion. (c) If space permits, low piles are preferable, as the coal is thus more exposed to the air and better cooled than in high piles; also, in case of heating it can be more readily and quickly moved. A disadvantage in high piles is the greater difficulty of moving the coal quickly, if necessary. The idea that a high pile causes heating at the bottom is erroneous, since as many fires take place near the top as near the bottom and near the outside as near the interior of the pile. If possible the coal pile should be divided by alley ways so as to facilitate rapid loading out of the coal in case of necessity so that an entire coal pile may not be endangered by a local fire. (d) Much of the attempted ventilation of coal piles in the United States has been inadequately done by the use of only an occasional ventilation pipe which has been not much more than a place in which to insert a thermometer for reading temperatures. The practice of placing ventilating pipes close together has been used in Canada and is reported to have been effective. (e) Water is an effective agent in quenching fire in a coal pile if it can be applied in sufficient quantities to thoroughly cool and put out the fire, but a small amount is ineffective. Unless there is an ample supply of water to thoroughly quench the fire and cool the pile, it is dangerous to add any water to a coal pile. (f) Coal of different varieties should not be mixed in storage if this can be helped, for one coal that has a greater susceptibility to spontaneous combustion than the other may jeopardize the safety of other coals that are not so liable to spontaneous combustion.

Some Practical Storage Suggestions

5. The effect of storage on the value of coal: (a) The heating value of a coal as expressed in B.t.u. is decreased very little by storage, but the opinion is widespread that storage coal burns less freely when fired in a furnace. Experiments indicate that much of this can be overcome by keeping a thinner bed of coal on the grate than is kept with fresh coal and by regulating the draft. (b) The coking properties of most coals seem to be decreased as a result of storage. (c) The value of coal for making illuminating gas is not decreased as a result of storage. (d) The deterioration of coal stored under water is negligible and such coal absorbs little extra moisture. If only part of a coal is submerged, the part exposed to the air is still liable to spontaneous combustion.

6. Additional precautions: (a) The best preventative of loss in coal storage is to regularly inspect the pile and if heating occurs (up to 150 deg. F.) to keep close watch on the pile, and if the heating increases to 175 or 180 deg. to remove the coal as promptly as possible from the spot affected and thoroughly cool it before piling it again. (b) Storage appliances and arrangements should be so designated as to make it

possible to load out the coal quickly if necessary, and the coal should not be stored in large piles unless provision is made for loading it out quickly. (c) Pieces of wood, greasy waste or other easily combustible material mixed in a coal pile may form a starting point for a fire, and every effort should be made to keep such material from the coal as it is being put in storage. (d) It is important that coal in storage should be kept from such external sources of heating as steam piles, because the susceptibility of coal to spontaneous combustion increases rapidly with an increase in temperature.

These are but some of the problems due to war conditions, and while there may be some temporary embarrassment and inconvenience resulting from them, I am personally convinced that as a result of the war the coal industry will be benefited. On account of the prominence given to the subject of coal and the widespread discussion of it, the coal industry is even now better known and more talked of than any other industry in the country. P. T. Barnum once said that he did not care what people said about him so long as they said something, for in that way they thought of P. T. Barnum. So it will be with the coal industry. If people think about it enough, they must ultimately know something about it and have a more intelligent understanding of the coal problem than they have had in the past and thus be more sympathetic to the miner and operator and not antagonistic as they have always been.

In the second place, the producer of coal by being compelled to analyze his operating conditions should be better able to produce coal efficiently and relatively more cheaply, although I do not believe that coal will ever recede to the low prices at which it was formerly mined and sold. No business of the magnitude of the coal business has ever been so disorganized prior to war conditions as was the coal business, but one of the very things sought to be accomplished for years has come to pass; namely, the formation of a National Coal Association, which had been tried many times in the past but always failed due to the fear of the Sherman law. People have become so accustomed to thinking in billions that combinations in the future will not nearly have the same frightfulness that has been true in the past. Under war conditions and sometimes under compulsion, labor and capital have come closer together and each side has learned many of the inner secrets of the other, so that there should be less distrust in the future than there has been in the past. Frightful, therefore, as is the war, I believe its effect on the coal industry will be a beneficial one.

New Bulletin for Large Coal Users

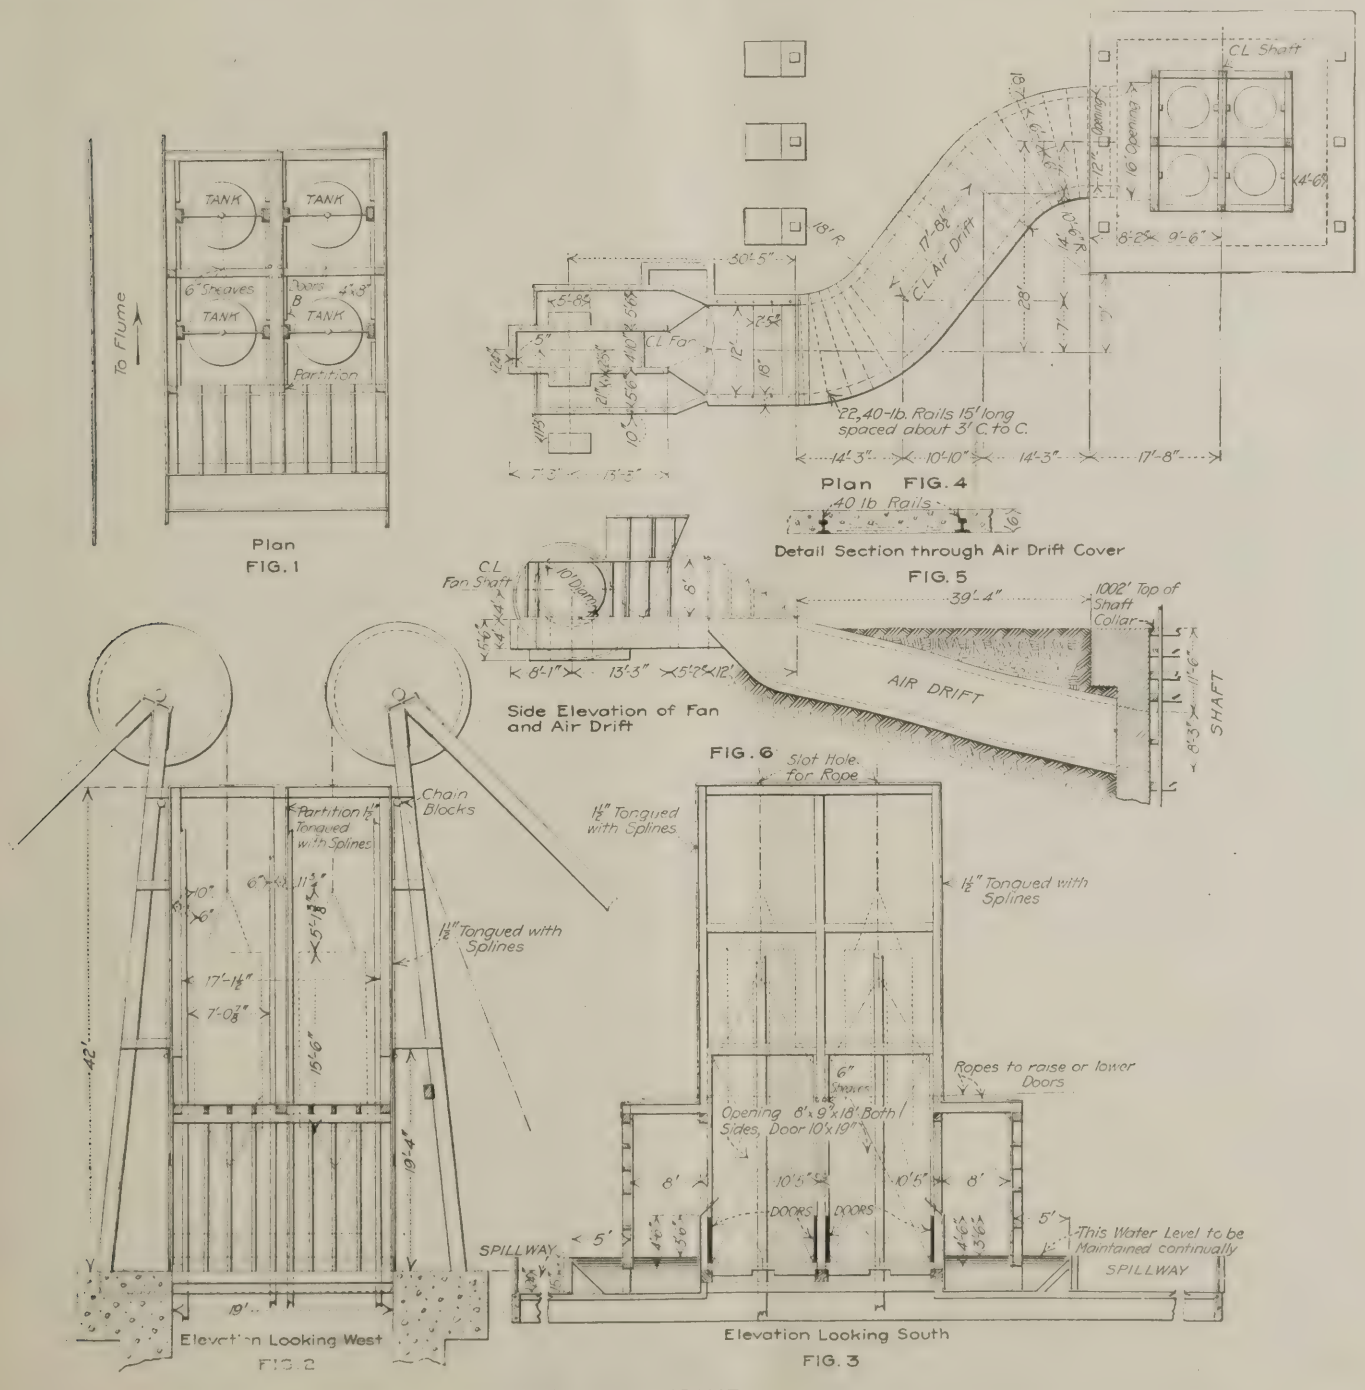
At this time, when fuel engineers and manufacturers are deeply interested in the conservation of fuel in order that those industries essential to winning the war may not be handicapped, they will welcome a publication just issued by the Bureau of Mines of the Department of the Interior, giving thousands of analyses of coals from many hundred mines in the United States, for these analyses enable the users of coal to realize the amount of heat they are buying.

Bulletin 123 "Analyses of Mine and Car Samples of Coal Collected in the Fiscal Years 1913 to 1916," is a continuation of the sampling and analyzing of the coals of the country begun by the Federal Government in 1904. It is the third of the series, Bulletin 22, "Analyses of Coals in the United States," which can now only be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 85c., being the first. The second bulletin of the series, Bulletin 85, "Analyses of Mine and Car Samples of Coal Collected in the Fiscal Years 1911 to 1913," is still available for distribution by the Bureau of Mines.

The present bulletin presents analyses and descriptions of samples collected during the fiscal years 1913 to 1916. In order that the material in this bulletin may be used to supplement that presented in Bulletins 22 and 85, the same plan of geographical classification has been followed, the analyses and descriptions of the samples being grouped in alphabetical order according to the state, county and town near which the mines or prospects sampled are situated.

The three bulletins, which do not conflict, constitute an extensive analyses of the coals of the United States and should prove of great value to those who purchase large quantities of coal. The day has passed when the industries buy coal as coal. They now buy heat units and know what they are buying. Bulletin 123 is of no particular interest to the domestic consumer of coal. It is for the industries that require large quantities of coal and to whom the cost of coal now is an increasingly large factor in the conduct of their works.

Copies of Bulletin 123 may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D. C., as long as the present edition remains.



Legal Department

KENTUCKY MINE PROP LAW — In affirming judgment against defendant mining company for death of a miner caused by a fall of slate at a place where he and his buddy were engaged in drawing pillars, the following points were decided by the Kentucky Court of Appeals, in the case of Kirk vs. Borderland Coal Co., 203 Southwestern Reporter, 534. The Kentucky statute, providing that "every workman in need of props, cap pieces and timbers shall notify the mine foreman or an assistant mine foreman, or any other person delegated by the mine foreman, of the fact at least one day in advance, giving the number, size and length," etc., applies only to those miners who are charged with the duty of propping. The custom of a mine may be proved for the purpose of showing upon whom the duty of propping devolved. Even if the company's rules purport to require every miner to do his own propping, waiver of the rule in general practice may be proved. When a coal operator designates employees to do necessary propping, such employees become representatives of the operator for that purpose and their negligence is actionable negligence of the operator, if it results in injury to other miners. Where a miner is assured by one in authority that a given place of work is safe, the miner may continue at work there without assuming the risk of being injured through the existence of some dangerous condition negligently permitted by his employer to exist. Such assurance may be given in implied, as well as express, terms. Hence statement by a timberman to a miner, "All right, so long," may be found to have been an assurance to the miner that a place which it was the timberman's duty to prop, if propping was reasonably necessary, was safe.

Shaft for Water Hoisting and Ventilation

ABOUT halfway between Lansford and Tamaqua, Penn., on Locust Mountain, there is a unique installation at shaft No. 10 of the Greenwood colliery of the Lehigh Coal and Navigation Co. It is known locally as a "water seal"—a scheme which permits of the same shaft being used both for ventilation and water hoisting. The combining of the two functions—ventilation and hoisting of materials such as water, coal, etc.—has been practiced on the continent of Europe for some time, but as far as known the first application in the United States is at the Greenwood shaft of the Lehigh Coal and Navigation Co. The Greenwood colliery is in the Panther Creek Valley, about three miles west of Lansford. The workings are on the north side of the valley, mainly in the south dip seams. It is interesting to note the development at this old operation. It was first opened up in 1860 by a water-level tunnel which cut the Primrose bed and the Mammoth seam in two places.

In the early days of mining in the Panther Creek Valley, the coal was started on its way to market over planes and gravity roads, and thence by water transportation to its destination. The coal from the Greenwood tunnel in 1860 was transported to Coaldale to the foot of No. 2 plane; it was hoisted up this plane and then run by gravity one mile east to the foot of No. 1

FIGS. 1 TO 6. DETAILS OF WATER SEAL AND FAN AT SHAFT NO. 10, GREENWOOD COLLIERY

plane; after being hoisted up this latter plane to Summit Hill, the coal was run by gravity on a railroad to Mauch Chunk, where it was loaded into boats and shipped to market via the Lehigh Canal. In the '60's railroad transportation was not carried on by means of 100,000-lb. capacity steel hopper cars equipped with Westinghouse air brakes. The little 5-ton wooden "jimmies" with their hand brakes were the terror of railroad officials. It often seemed as though they did not wait for even a legitimate excuse to leave the rails, and wrecks were common occurrences.

The gravity road from Summit Hill to the Lehigh Canal and the planes used to transport the empties back to Summit Hill have long outlived their usefulness as part of a coal-transportation system, but as the switchback of today contribute to the pleasure of tourists. The old method of transportation gave way in 1872 to

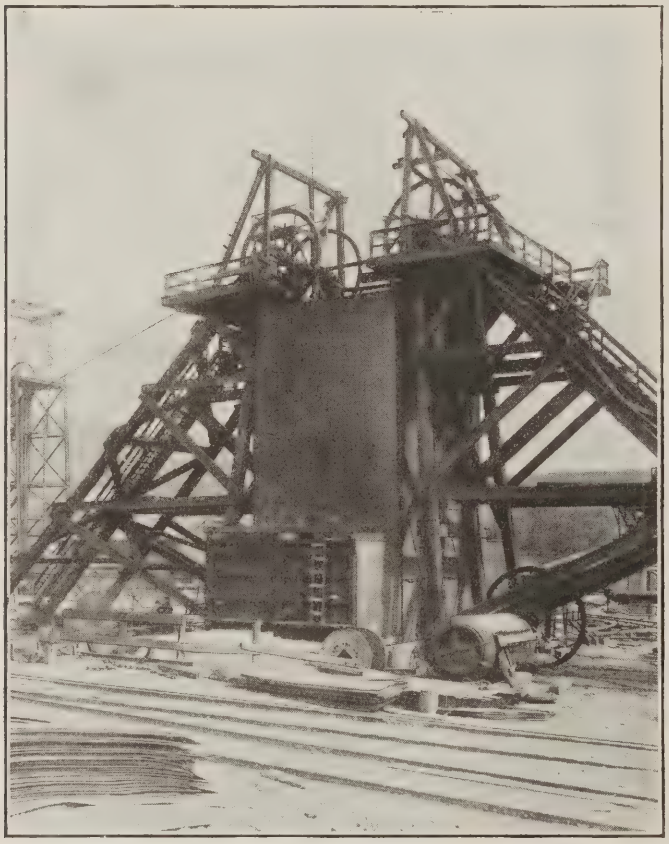


FIG. 7. HEADFRAME AND WATER SEAL AT SHAFT NO. 10

the one in vogue at the present time; the Locust Mountain was tunnelled by the Lehigh Coal and Navigation Co. at Lansford, and thenceforth coal from the Panther Creek Valley went to market by rail via the Nesquehoning Valley to Mauch Chunk, where it reached the main line of the railroad, since leased to the Central Railroad of New Jersey.

Continuing the description of the development of the Greenwood colliery, in 1870 a slope was sunk 250 ft. in the Mammoth seam from the water level; in 1880 the slope was extended 250 ft. for a new lift. A coal shaft was sunk in 1905 to develop a new level below the slope workings; and two years ago another shaft was sunk to open up a new level under the old shaft level. When the slope was sunk in 1870, engines, boilers and a fan were placed on the mountain back of the outcrop of the Mammoth seam.

In 1904 a new breaker was built at the Greenwood mines; a boiler house was erected having in mind utilizing the steam from this plant for power for the breaker and for a proposed water shaft which was started the following year. The boiler house on the mountain was now abandoned and a 2200-ft. steam line was established to operate the engines and fan at the Mammoth outcrop. The water shaft, which was sunk in 1905 to a depth of 620 ft., has four compartments; four water tanks are operated in the shaft by two pairs of engines, one pair on either side of the shaft, as indicated in Fig. 7.

In 1914 the slope workings were robbed out, the slope was abandoned and the engines were utilized to sink a new shaft. Various complications connected with the old ventilating system at the Greenwood colliery made it necessary to revise the method of ventilation and erect a new fan. After considerable discussion it was decided to utilize the water shaft and make it do double duty for air and water rather than to sink a new air shaft at a cost of $60,000. The available area of the water shaft is 256 sq.ft. As 3000-gal. tanks were to be used of a diameter of 5 ft. 10¼ in., the horizontal area of the four tanks would amount to 107.5 sq.ft. Thus, after subtracting the area of the four tanks, 148.5 sq.ft. horizontal shaft area would be left available for ventilation. Then it was a question whether the tanks, when in operation, would have any detrimental effect on the air current. On account of the large area available it was decided that they would not seriously interfere with the ventilation. Since the fan has been in operation a test showed that this conclusion was justified.

The Greenwood colliery is a prominent operation in the Panther Creek Valley, and its name lends selling power to the coal of the Lehigh Coal and Navigation Co. "Summit," "Greenwood" and "Old Company's Lehigh" are well-known trade names. The boiler plant at this mine stands out prominently on the mountain side. Its 16 stacks indicate its size and bespeak the power required to carry on the various operations connected with the mining and preparation of the Greenwood coal. This boiler plant is shown at the right of Fig. 8. The headframe of the water hoists is in the center, and the new fan and its engine house are prominent in the foreground. The top of the Greenwood breaker shows immediately to the left of the boiler-house stacks.

Like many effective operations, the idea embodied in the water seal and also its construction is extremely simple. The principal problem in the case in question was to make a water seal which would permit of delivering water through it from the 3000-gal. tanks without disturbing the ventilation. The solution of this problem as worked out by the Lehigh Coal and Navigation Co. has proved to be a complete success, and the construction details are given in the accompanying illustrations.

In Fig. 3 is shown a cross-section through the shaft and the water seals, one on either side of the shaft. To permit of handling the tanks without disturbing the ventilation, the shaft was practically extended by a casing 42 ft. above the headframe foundations. This casing is built of 1½-in. boards tongued with splines (similar to tongued and grooved). Excess height is

provided in this casing to allow for ample space in which to handle the tanks at the discharging stage of their operation. In the cross-section (Fig. 3) the water tanks are shown dotted in their discharging position.

When the water leaves the 3000-gal. steel tanks it flows into the wooden tanks at the side of the shaft, overflows from them to a spillway and is carried off by a flume to a near-by reservoir. One end of these wooden tanks is included in an extension of the shaft casing, part of which drops about 1 ft. below the ordinary level of the water, thus acting as a seal or lock to the air in the shaft but permitting of free passage of water underneath. The hood over the shaft end of this wooden tank is shown in Fig. 7. In this illustration the water is welling out over the outside end of the wooden tank as a steel tank is discharging into the inside portion. It is an interesting sight.

Other features connected with the casing over the shaft include arrangements for opening it to remove the steel tanks for repairs or to do other necessary work in the casing while the fan is running. On both sides of the casing are 10 x 19-ft. vertical doors through which the tanks may be removed. When these outside doors are to be opened the top of the shaft is first closed by dropping another set of doors which prevent disturbance to ventilation. A vertical partition in the center of the shaft top casing permits of one hoist being operated while the other is being repaired.

Closely associated with the water hoists at shaft No. 10 is the fan and the method of ventilating the Greenwood workings through the same shaft. At the time plans were being considered for unwatering and ventilating this mine, a ventilating system was projected which showed the proposed workings of the entire mine, noting sizes of all airways, gangways, overcasts, etc. The resistance was calculated for the conditions which would exist when the development work had reached the point where the maximum resistance would be encountered. The number of men that would be employed in the mine was estimated, also the number of splits, and the number of men that would probably be employed on each split.

Thus in this manner it was ascertained that conditions would require a fan with a capacity of about 200,000 cu.ft. of air per minute. The Jeffrey Manufacturing Co., of Columbus, Ohio, furnished a fan which met the necessary requirements. Its normal capacity was 200,000 cu.ft. per minute at 170 r.p.m. and 125 brake-horsepower. The reversing mechanism of the steel fan included steel reversing doors for the chimney, hinged to its front and provided with the usual operating parts. The casing was also provided with all necessary side drift reversing doors. The fan was constructed of $\frac{3}{16}$-in. steel plate and a steel chimney with 110 sq.ft. area. The fan gives the following results according to the various speeds of the operating engine:

FIG. 8. HEADFRAME AND WATER SEAL ALSO OTHER PLANT AT GREENWOOD COLLIERY

R.p.m.	Volume, Cu.ft.	Gage, In.	Brake-Horsepower
170	200,000	3.00	125
128	150,000	1.70	54
86	100,000	0.75	16
44	50,000	0.20	4

An interesting test was made in connection with shaft No. 10 with which this fan is connected. Meas-

urements of air were taken when water was being hoisted up the shaft and again when the tanks were not in motion. When hoisting water, the area of the main airway inside equals 11.5 × 7 = 80.5 sq.ft. The velocity of the air equals 1705 ft. per minute, which gives 137,252 cu.ft. per minute. When not hoisting water, the velocity of the air equals 1770. These conditions give 142,485 cu.ft. per minute. The water gage at the fan was 2.8 in. and the speed of the engine 86 r.p.m. Thus it is seen that the operation of the tanks in the shaft does not have a very detrimental effect on the air currents, due chiefly to the large shaft area. Normally the fan is run exhaust, as the workings in parts of the Greenwood mines are very gassy.

A general view of the fan and its engine house is given in Fig. 8; the details of construction of the fan and drift are shown in Figs. 4, 5 and 6. In locating the fan it was placed on the north side of and 28 ft. west of the center line of the shaft, so as not to interfere with the piers for the shaft headframe. Connection with the shaft was made by a concrete conduit 12 ft. wide and 8 ft. high, giving an area of 96 ft. The fan house was constructed of hollow tile plastered with cement. The roof was made of protected corrugated steel. Thus fireproof construction was used throughout.

It would be interesting to see how the air-lock scheme would work out when applied to a shaft through which coal is hoisted and which is also used for ventilation. It has been worked out in practice in Europe and might readily be accomplished by having the top of the shaft housed in similar to the method at the Greenwood colliery. Instead of having the mine car discharge inside the housing the cage could pass through an air lock and the coal be dumped outside. This air lock might be equipped with two sets of doors, capable of being automatically opened and closed by the cage in its passage through the lock. When one set of doors is open the other should be closed.

Naturally, a scheme of the kind outlined would likely only find application in special cases similar to the proposition which confronted the Lehigh Coal and Navigation Co. at its No. 10 shaft. In the case in question a considerable saving was effected by using a shaft already sunk for both ventilation and water hoisting. In planning a new operation, where two openings to a mine are required by law, it is questionable whether the air-lock scheme would often be advocated. In a number of drift mines in bituminous regions, especially before development is well under way, a similar plan is frequently used, for a time at least. In this case the fan may be placed at the mine mouth of a double-entry system; the air travels in in one entry and out the other. The return airway is used as a haulageway until within a thousand feet or so of the mine mouth, when a change is made to the intake. A trip of cars in passing out of the mine goes through an air lock, thus not interfering with the ventilation.

George W. Wickersham, former Attorney General of the United States, says: "Business as usual means waste as usual."

Relined a Mine Shaft with Cement Gun

During the past four years, ten mine shafts on the Iron Ridge in Minnesota have been relined with precast concrete lumber. In many others monolith concrete has been used. Recently the cement gun has been employed to reline the Penobscot pump shaft of the Oliver Iron Mining Co., at Hibbing. This shaft, lined with steel sets and 2-in. wood plank, was sunk in 1911. It was finished in 1912, reaching a depth of 231 ft. All the water from the Hull-Rust pit, one of the largest open-pit mines in the world, is pumped out through this shaft. Originally the pumps handled 1000 gal. a minute, but now the discharge is only 400 gal. in the same time.

The shaft is about 11½ x 6 ft., with two compartments 5½ x 6 ft. The steel sets are made up of 6-in. beams of H-section and the buntons are 6-in. I-beams. The sets are spaced on 4-ft. centers.

The work of repair, which is to be described, was started at the top and proceeded at the rate of two sets

METHOD OF FASTENING REINFORCEMENT STEEL—SECTION B-B

per day, a daily advance of 8 ft. Concrete was placed over the wood lining in two layers, each 2 in. thick. Sollars or temporary platforms were put in every 15 to 20 ft. in order to prevent the sand from the cement gun from dropping down the shaft, and also to prevent accidents from falling materials. The shaft ladders were removed as the work proceeded, in order to give the men sufficient operating room. The sets were concreted in order, except those at which the sollars had been placed. After the concrete had hardened in the sets above and below the sollar sets, the sollar was removed and the set on which it rested was concreted.

Before, however, the cement-gun work was started, reinforcing was placed all the way down the shaft. This was wire mesh, cut into lengths of 4 ft., so that when placed between the sets it would curve out, forming tension reinforcement near the interior face. To hold the reinforcement in place hook spikes made from ¾-in. rods were driven into the timbers, close to the sets. The sand and cement as mixed in the cement gun was fed to the nozzle through a 1¼-in. hose. Wear on the

rubber connections from the gun to the delivery hose made it necessary to replace these connections several times. Otherwise no repairs were needed. Six men were employed besides the foreman, who gave only a part of his time to this job. Three men measured the sand and cement, mixed the materials and carried the mixture to the cement gun. One man attended to the gun and two men were down in the shaft handling the nozzle. While one was busy with the nozzle the other would be trimming. Sand was obtained from a bed in an open-pit mine and brought to the job in 7-yd. wooden dump cars, being screened through ¼-in. mesh and dried with steam coils.

Though the workmen had no experience to begin with, they were of an intelligent laboring class and were able to do the work satisfactorily after a little training. For a 10-hour day the ordinary work of six men was three sets or 12 ft., applying a layer of one coat 2 in. thick. The best results were obtained when the sand was thoroughly dried and mixed with the cement before being placed in the cement gun, and batches of 1 to 1½ cu.ft. were handled by the gun much more satisfactorily than larger batches. With these precautions the flow to the hose could easily be regulated, making it possible to place the concrete smoothly on the walls of the shaft.

Sand was heated in a specially built drier seven coils wide and seven coils high and 12 ft. long, made of 1½-in. pipe. It would sift down through these coils and be perfectly dry when it reached the bottom. A double ¼-in. mesh screen, placed on a slant, was used directly above the coils. Experience with this improvised drier showed that it would have been more efficient if the pipes had been shorter. Steam was obtained from the stationary plant at Penobscot mine, while the air used in operating the gun was furnished by a Westinghouse air pump, furnishing about 220 cu.ft. a minute, carrying 70 lb. pressure. At the nozzle the air pressure was from 20 to 22 lb., and water pressure 100 pounds.

In experimenting it was found that if the sand and cement were placed in the gun separately and then mixed, there was much waste material from the rebound when the concrete was shot on the wall. After the dried sand and cement were mixed before being put into the gun, this waste material decreased materially.

Sollars were put in every three or four sets and were cleaned every day. They were made of 2-in. plank and extended 4 in. on either side of the compartment and so could not slide out of place. At the end of each day's work the hoses, nozzles and gun were completely cleaned.

After the shaft was lined the water gave no further trouble, and the mine officials were so well pleased that they decided to use the cement gun in pointing up joints in the Philbin shaft where precast lumber has been used for the lining. Before treatment water was seeping into the shaft below the 75-ft. level, but this was stopped by a single coat of cement-gun concrete.—*Engineering News-Record.*

Liquid fuel has a simple molecular structure, and the ease with which the light oils are changed to vapor make these oils readily adaptable to many purposes for which gas is used.

Record July Shipments of Anthracite

The shipments of anthracite for July, as reported to the Anthracite Bureau of Information at Philadelphia, show gratifying increases both over June of this year and over July, 1917. The record for last month was 7,084,775 gross tons, against 6,867,669 tons in June, and 6,724,252 tons in July of last year, the increases being respectively 217,106 tons and 360,523 tons. The shipments in July were the largest ever made in that month in the history of the industry, and have been exceeded only twice—in March of this year when they amounted to 7,276,777 tons, and in October, 1917, when they were 7,110,950 tons. The total shipments for the first four months of the present coal year—April to July, inclusive—have amounted to 27,208,073 tons against 26,283,113 tons for the same period of 1917.

Not the least gratifying showing in the returns for last month is a substantial increase in the output of domestic sizes, which in the earlier months of the year had shown a relative decline. The shipments of domestic sizes, including pea coal, in July were 4,634,651 tons, an increase of 135,675 tons over the preceding month. In fact, more than 60 per cent. of the total increase was in the domestic sizes of coal. The shipments by railroads were as follows:

	July, 1918	July, 1917	Coal Year, 1918	Coal Year, 1917
P. & R. Ry.	1,420,624	1,256,316	5,356,093	4,943,301

Molecular Consistency of Gases

According to the kinetic theory, gases consist of freely moving molecules. The contacts or collisions among molecules of different nature produce chemical action. Therefore for complete combustion to take place in the mixture of gases, each molecule of the combustible must come in contact with the number of oxygen molecules required to burn it. The concentration or number of molecules of combustible gas and oxygen in a unit volume will influence the number of collisions taking place. According to the law of mass action, the velocity of a chemical reaction in the combustion process is proportional to the products of the concentrations of the oxygen and the combustible substances; that is, if one molecule of substance A reacts with one molecule of substance B the velocity of the reaction at any moment is proportional to the product of the number of molecules of A and B present in unit volume. If several molecules of one substance are taking part in the reaction, the concentration of that substance must be raised to the corresponding power. Thus if one molecule of substance A reacts with two molecules of substance C the velocity of the reaction will be proportional to the number of molecules of substance A in unit volume multiplied by the square of the number of molecules of substance C in unit volume. Thus it can be said that the velocity of a chemical reaction increases when the concentration of the reacting substances increases.

DEPARTMENT OF HUMAN INTEREST

Eye Hazard in Coal Mining

The bulletin of the Pennsylvania Department of Labor and Industry, Vol. IV, Series of 1917, No. 7, gives the following information regarding eye accidents in the anthracite and bituminous coal industries of Pennsylvania. The classification forms are prepared for ordinary industrial accidents, consequently some of the subdivisions seem awkward to a mining engineer:

Cause of Accident	Eyes Lost		Other Compensable Accidents		Non-compensable Accidents	
	Anthracite	Bituminous	Anthracite	Bituminous	Anthracite	Bituminous
Machinery						
Boiler, steam pipes, etc.						1
Transmission apparatus					1	
Adjusting machine or work						1
Operating and feeding						1
Oiling					1	
Cleaning					1	
Repairing				1	1	1
Breaking of machine or work				1	2	2
Flying objects	1	1	7	7	74	89
Explosives, electricity, fires, hot and corrosive substances						
Corrosive substances			4	3	15	16
Electricity	1		1	2	9	28
Explosives	11	10	19	16	9	7
Hot substances and flames			2	4	21	21
Conflagration						1
Falling objects						
Rock and earth	3	4	50	76	119	251
Dropped by other persons					2	
Falling from trucks and vehicles						1
All others			3	7	13	12
Fall of persons						
From ladder						1
From scaffolds or platforms			1	1	1	
From vehicles						1
From other elevations					1	
Into openings other than excavations					2	1
On level			2	2	14	5
Handling of tools and objects						
Tools in hands of injured persons	1	3	2	14	21	32
Tools in hands of fellow workmen		2		2	3	4
Handling sharp objects			1			
Loading and unloading			1		8	6
Carrying and lifting objects (not loading or unloading)				1	2	7
All others			1	2	9	12
Power vehicles on track						
Coupling or uncoupling cars					1	1
Defective equipment						1
Fell from, over or into			1		1	3
Loading or unloading material			3		11	6
Struck by car or engine			1	1	1	
Struck by overhead or side obstruction				2	2	2
Collisions				2	1	4
Derailments and replacing cars				2		8
Miscellaneous						
Stepping on nails				1		1
Running into or striking against objects			4	4	21	17
Poisonous substances		2		2		1
Flying objects (not from machines, etc.)	39	41	257	279	751	956
Animals	1	2	4	7	12	6
Intentional violence		1		1	3	3
All others		1	2	3	5	4
Total	57	67	366	443	1,138	1,514

Looking over these figures we soon see that the larger number of accidents are from falling objects (rock and earth) and from flying objects (not from machines, etc.). The number of these accidents seems to suggest the use of goggles by miners. There were 7 eyes lost, 126 compensable accidents and 370 noncompensable accidents from falling rock and earth, while there were 80 eyes lost, 536 compensable accidents and 1707 noncompensable accidents from flying objects (not from machines).

In view of the small number of men engaged in machine shops around the mines the number injured shows that the hazards are great. The three causes "tools in hand of injured persons," "tools in hand of fellow workman" and "handling sharp objects" explain 6 lost eyes, 19 compensable accidents and 60 noncompensable. Those eye accidents to miners and shop workers which may be avoided by the use of goggles can roughly be computed by adding together the accidents, compensable and noncompensable, from falling rock and earth, from flying objects (not from machines) and from tools. The number of eyes lost thus totaled was 93 out of 124. The compensable accidents amounted to 680 accidents out of 809 accidents to the eyes. The noncompensable accidents account for 2137 out of 2652. Thus the eye hazard would be almost entirely avoided if protection for the eyes were provided for these two classes of men.

The following estimate has been made by F. H. Trego, of the Mine Safety Appliances Co., of the losses due to the eye hazard in the Pennsylvania anthracite mines during 1916, based on these figures:

57 lost eyes at $1,675 per eye	$95,475
366 compensable eye accidents including medical attention at $75 per accident	27,450
1138 noncompensable eye accidents, including time lost and medical attention at $18.93 per accident	21,542
Total	$144,467

The loss from the eye hazard at the bituminous mines of Pennsylvania during 1916 is figured as follows:

67 lost eyes at $1,675 per eye	$112,225
443 compensable eye accidents, including lost time and medical attention at $75 per accident	33,225
1948 noncompensable eye accidents, including lost time and medical attention at $22.16	43,168
Total	$184,410

The figures for lost time and medical attention in noncompensable accidents are based on the average experience for all noncompensable accidents of the year 1916 in the State of Pennsylvania. According to this method of calculation the number of days lost in the Pennsylvania anthracite mines for noncompensable eye accidents would be 6475 or 5.69 days per accident; in the Pennsylvania bituminous mines it would be 12,311, or 6.32 days per accident, if the severity of noncompensable eye accidents is equal to the severity of all noncompensable accidents at Pennsylvania mines of like character.

Buried Under Rock and Yet Lives

By E. H. Graham

It happened within the past month. He was an inspector who, desiring to get a quick fall of roof in a worked-out place, seized an ax and began chopping one of the few remaining timbers. The miners, having recovered the pillar, had removed all the timbers that could be recovered with perfect safety. They warned

our friend that he was in danger, that what he was attempting was unnecessary as the roof would break the remaining timbers in a short time and thus give the desired fall, but impatient and overconfident he chopped away until a piece of slate became dislodged and caught him, pinning him to the ground by his foot so that he could not extricate himself.

The one witness tried hard to release the victim, but the piece of slate was too heavy for him, so he ran for assistance. During his absence and before the rescue party could arrive, the thing expected by the miners happened—the roof fell, more than 15 tons of it, carrying with it the remaining timbers. When the rescue party arrived, they saw a mass of rock and slate 6 ft. in height, but no inspector. The work of search was immediately begun and after four hours of the hardest and fastest kind of work they came upon the body, which they discovered had been entirely entombed by the mass of rock and slate.

And here a miracle—the supposed victim was not injured at all. Providence is kind at times, even to the foolish.

When the roof fell two of the large timbers, which came with it, fell one on either side of the prostrate inspector, and by some unaccountable combination of circumstances large pieces of slate and rock supported by these timbers took the weight of the entire fall, leaving the man unhurt. This accident without doubt illustrates just what has been the cause many times of fatal roof falls; only in those cases the man did not escape, and so no one has been able to tell just how the accident occurred.

Recovering timbers from worked-out places need not of necessity be a dangerous undertaking, if only experienced men do the work, and they do it with a liberal factor of safety. In the case cited all the timbers that could be safely removed had been recovered. The accident was due to the impatience of the inspector in his desire to hurry the fall.

Occasion may arise when it is desirable to cause a fall without waiting for nature to do its work. If so, a half stick of Monobel lashed to the timber will break it, or better still a hole can be drilled at an angle near the foot of a prop so as to terminate under it. By loading and firing this shot, the prop will be safely dislodged. This accident could have been avoided by either of these means. The miracle by which our friend escaped gave us valuable information, and from this recital of it all should profit

---

Patriotism and Cold Cash—The coal miners of the Colorado Fuel and Iron Co. have subscribed for $300,000 of War Savings Stamps and $67,000 to the Second War Fund of the American Red Cross. At Frederick alone, $30,000 worth of stamps were subscribed for. The Liberty Loan campaign also was most successful in interesting the mine workers. At Sopris the senior Red Cross organization has furnished 476 garments for refugees and the Italian women have started a knitting class.

COLORADO will soon have to give up the use of the word "camp" and call its mining villages "towns," so old-world are its activities and permanent its homes. One illustration shows a colored Red Cross chapter in session at Lester, and another a flag-raising at Cameron. Both "camps" are owned by the Colorado Fuel and Iron Company.

Who's Who In Coal Mining

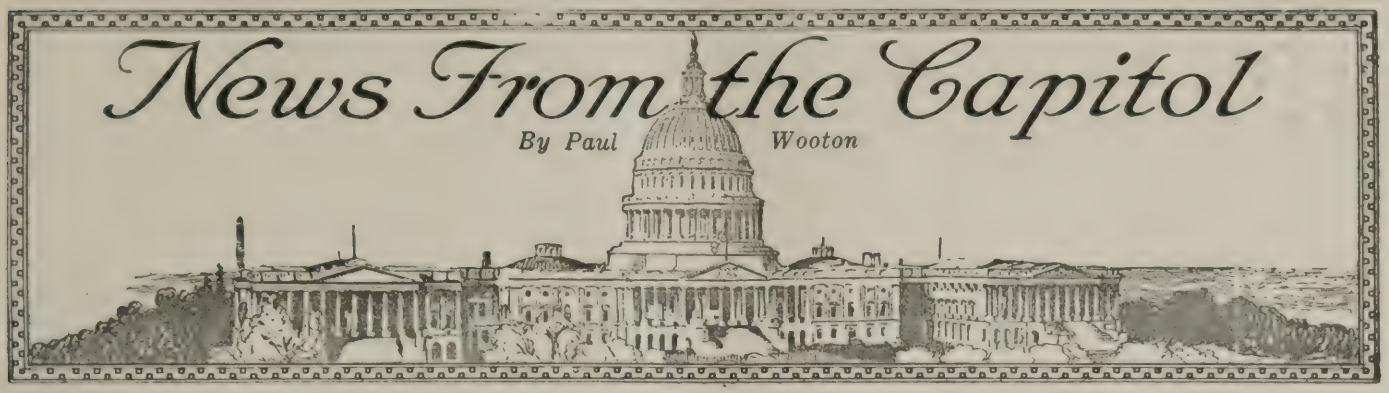
Joseph Gardner Bradley

If there is one trait which Joseph Gardner Bradley, chairman of the executive committee of the West Virginia Coal Association and incidentally president of the Elk River Coal and Lumber Co., possesses to an eminent degree it is his broad-mindedness—his ability, if you please, to see both sides of a question—and to realize the viewpoint of others. In short, his is a mind which perceives actualities. It will thus be easy for the reader to form some conception of how fortunate the West Virginia Coal Association was in securing a man of his caliber for its guiding genius although,

JOSEPH GARDNER BRADLEY
President of the Elk River Coal and Lumber Co. and Chairman of the Executive Committee of the West Virginia Coal Association

parenthetically speaking, Mr. Bradley is so innately modest that he would promptly enter a disclaimer to the statement that he was the guiding genius of anything, for the Association president is not a man who obtrudes himself anywhere yet whose personality and achievement have made him a recognized figure in West Virginia both in the public and industrial life of the state.

Mr. Bradley is not a native of West Virginia, but no man could have become more closely identified with the state in his 15 years of residence there, during which period he has entered actively into the life of the state, than J. G. Bradley. Antecedents do not always make the man, but if he is of the right material the character, mentality and ideals inherited from his progenitors are at least a foundation upon which to build, and it is at least interesting to trace a man's origin to see what he has made of his opportunity.



Joseph Gardner Bradley is a grandson of the late Joseph P. Bradley, Associate Justice of the United States Supreme Court, and of J. Donald Cameron, who was elected to succeed hs father, Simon Cameron, as a United States Senator from Pennsylvania.

A "September morn" in 1881 witnessed the advent of Joseph Bradley into this world at Newark, N. J., and it was at Mrs. Craven's School and the Newark Academy that he received his early education, later attending St. Mark's School at Southboro, Mass., in preparation for Harvard College where, after finishing his college course, he attended the Harvard Law School. To friends, however, Mr. Bradley has at times expressed the belief that his real education began 15 years ago on Buffalo Creek, West Virginia, and that his real education has been obtained there. If such be the case he has taken many degrees from the School of Experience, for he entered the employ of the Buffalo Creek & Gauley R. R. at Dundon, Clay County, West Virginia, as right-of-way agent. It was not long before he was promoted to be superintendent and in turn secretary and treasurer of that company, and then general manager, treasurer and president of the Elk River Coal and Lumber Co., which owns the Buffalo Creek & Gauley R. R. and 75,000 acres of coal and timber lands in Clay and Nicholas Counties, on which it has developed one of the best known fields of low sulphur gas coal. This it markets through offices in Columbus, Ohio, and Philadelphia, Penn., as "Dundon Coal," its coal operations being located at Widen, West Virginia, and its timber operations at Swandale, West Virginia.

Mr. Bradley has never failed to respond to any calls made upon him for public service and has given his time freely and willingly to such service, particularly since the United States entered the war, so much so in fact that the only home this hard-worked West Virginian has is on railroad trains. He has not sought office, but he was elected as a delegate from West Virginia to the Republican National Convention at Chicago in 1916.

Mr. Bradley had occasion not long ago to say in speaking of the aims of the West Virginia Coal Association: "It is interested in promoting close coöperation with the over-burdened State Department of Mines; in decreasing the hazards of the industry; in stabilizing it; in improving sanitation; promoting welfare work and seeing that it receives fair play. The West Virginia Coal Association has justified its existence in the past, and as time goes on and it continues to render service to both the industry and the community, new fields will open for its activities, for the day of collective industrial activity is rapidly approaching us; the markets of the world become open to the United States as they have never, save in theory, been before."

It is interesting to note that at the surface of the fuel bed the combustible gases represent 35 to 65 per cent. of the total heat value of the coal. This means that under ordinary operation of the side-feed furnace about one half of the total heat in the coal is developed in the fuel bed, the other half being developed in the combustion space. Among other factors, it depends upon the size of the combustion space how much of the 50 per cent. of heat left in the combustible rising from the fuel is developed.—*Bureau of Mines Bulletin No. 135.*

Storage Policy of Fuel Administration

Maximum limits of storage for bituminous coal have been ordered by the Fuel Administration as follows:

	Steam Coal			Byproduct and Gas Coal		
	Public Utilities, Days	Preferred Industries, Days	Non-Preferred Industries, Days	Byproduct and Gas Plants, Days	Preferred Industries, Days	Non-Preferred Industries, Days
Maine	120	90	30	120	90	0
Massachusetts, Vermont, New Hampshire, Northern New York	90	60	30	90	60	0
Connecticut, Rhode Island, Southern New York, New Jersey, Delaware, Eastern Pennsylvania	30	30	15	45	30	0
Maryland, District of Columbia, Virginia, North Carolina, South Carolina, Georgia, Florida, Western Ohio	30	30	15	45	30	0
Western Pennsylvania, Western Virginia, Eastern Kentucky, Eastern Ohio	30	20	15	45	30	0
Lower Michigan	90	45	20	60	60	0
Illinois, Indiana, Missouri	...	..	..	60	60	0
Wisconsin, Minnesota, North Dakota, South Dakota, Upper Michigan	...		..	90	90	0

The policy of the Fuel Administration in the matter of storage was explained by Dr. Garfield as follows: "Coal in excess of that required for current operations shall be delivered to plants not on the Preference List of the War Industries Board only when it is not in demand for use before Apr. 1, 1919, by consumers on said list; namely, railroads, the Federal Government, states, counties, public utilities, retail dealers or manufacturing plants on the Preference List. In carrying out this policy, allowance shall be made for differences in distance from the mines and for differences in transportation conditions which may require more or less storage at the beginning of winter to insure uninterrupted operation until the following spring."

The committee which determined upon the storage periods was constituted as follows: Federal Fuel Administrators; W. B. Bryan, of Kentucky; Harry F. Bryd, of Virginia; Joseph H. Frantz, of Ohio; W. N. Fitzgerald, of Wisconsin, and James J. Storrow, of New England; together with J. D. A. Morrow, Director General of Distribution, and A. M. Ogle, Director of States Distribution. The committee submitted the following report:

It is understood that these limits are mandatory and each Fuel Administrator is expected to see that the different classes of consumers are not allowed to exceed these limits. At the same time, it is understood that particular cases may require special treatment by a State Fuel Administrator, either by way of granting more stocks of coal than are indicated by these limits, or by restricting them to a less supply than indicated by these limits.

Where a State Administrator decides that the maximum limit should be exceeded in a special case for some special reason, he shall have authority to grant a revocable increase in writing for a specific added number of days. The administrator shall report each such specific case in writing immediately to the United States Fuel Administration at Washington, which may in writing disapprove the extension granted by him. Otherwise, it shall stand subject to action of the State Fuel Administrator.

Any company or concern which is permitted under the zoning regulations now or hereafter in force, to obtain coal from Illinois, Indiana, western Kentucky, or from mines west of the Mississippi River, may retain such reserve stock of coal as it shall have on the effective date hereof, on condition that such company or concern shall thereafter use screenings or mine-run only, for its current necessities, and shall obtain such screenings or mine-run for current use only from such last mentioned fields.

Production Bureau of Fuel Administration Ready to Co-operate with Mine Owners

The Production Bureau of the Fuel Administration is equipped to look after the interests of the operators in reference to the draft, voluntary enlistment, solicitations from private labor agencies and their advertisements, and to help them to get labor through the Government labor agencies. Julian B. Huff is in charge of this work.

The bureau is also prepared to handle quickly and efficiently any matters which should come up before the Priorities Board. It is desirous of being of help to the operators in obtaining necessary material. R. A. Rainey and D. D. Bush are in charge of this work. It is also investigating and taking whatsoever steps seem wise in reference to picnics, fairs, carnivals and various other celebrations which would probably result in a loss of tonnage. A. C. Dodson is in charge of this work.

The bureau is also in position to furnish literature of various kinds in connection with coal production and to supply speakers. This matter of propaganda is in charge of W. E. E. Koepler. Questions of car supply and any general matters should be taken up with George C. Foedisch. C. E. Stuart is looking after central power plants from which the operators are purchasing power.

In coöperation with the National Coal Association, the Production Bureau of the Fuel Administration is taking a census of the requirements of the industry for the next eighteen months. In this way it is hoped to secure definite information as to the amount of supplies which the mines will require. With this information at hand, it will be possible to take steps to prevent an

under supply of any needed material. Owing to the shortage of steel every effort is being made to prevent any overproduction. For instance, only a sufficient number of mine rails will be rolled to meet actual needs. With greater difficulty being experienced each day in meeting the nation's steel requirements, every precaution will be taken to prevent the tying up of this much needed product in supplies not immediately needed.

At present there is a shortage in a number of steel products, due to erroneous estimates of the amounts needed. It is believed the census will enable a much more intelligent handling of the matter in the future.

Kentucky Prices Now Fixed

Kentucky coal fields have been divided into five districts by the Fuel Administration, and prices, without the wage increase, prescribed as follows: District No. 1—$1.90, $2.15, $1.80; District No. 2—$2.10, $2.35, $1.85; District No. 3—$2.55, $2.80, $2.30; District No. 4—$2.20, $2.45, $1.95; District No. 5—$2.20, $2.45, $1.95. These prices are for mine-run, prepared sizes and screenings.

Exceptions are made in the following cases: Blue Gem Coal Co., $3.35, $3.80 and $2.40; Wallan-Jellico Coal Co., $3.25, $3.50 and $2.50; Elkhorn City Coal Co. and Guthrie Coal Co., $2.55, $2.80 and $2.30.

Contingent Fee Covenant Not Applicable to Coal Industry

Since rules and regulations have been promulgated governing the distribution of coal and coke which bring sales agents under rigid control, the Attorney General has ruled that the contingent fee covenant which the President has ordered inserted in all Government contracts is not applicable to the coal industry. Dr. Garfield submitted the following questions in regard to the matter:

1. Where coal is purchased by a jobber from an operator at a price below the mine price fixed by the President or the United States Fuel Administrator, can such jobber sell such coal to the United States Government at the mine price so fixed? Of course, in the case of such a sale the jobber would be the "contractor" and not the operator, and it would appear that the profit realized by the jobber might not be construed as compensation paid by the operator to the jobber for the procurement of the contract.

2. Is the above provision intended to prevent an operator from employing a sales agent on sales of coal to the Government where such sales agent receives as compensation for his services either a fixed price per ton or a percentage of the selling price? In the determination of this question it should be borne in mind that many coal operators do not maintain their own sales departments but employ established distributors of coal to act as sales agents under term contracts, on which such sales agents undertake to sell the output or a given quantity of the operator's coal for a fixed or percentage compensation.

3. Is the above covenant to be construed to prevent any agency of the Government from employing a distributor of coal as purchasing agent and paying such agent the commission allowed by Rule 3 of the Rules and Regulations in reference to licenses contained in Publication 22, inclosed herewith?

4. Are contracts between coal operators and railroads to be construed as Government contracts so as to require the insertion therein of the covenant quoted above? In answering this question the fact should be considered that a very large percentage of coal purchased by railroads in the past has been purchased (a) at the Government price through jobbers, who in turn purchase from the operators below the Government price; (b) at the Government price from sales agents, who receive their compensation from the operators; (c) at the Government price through purchasing agents employed by the railroad and paid by the railroad the purchasing agent's commission permitted by the above-mentioned Rule 2.

The Attorney General's ruling is contained in a letter dated Aug. 19, which reads as follows:

I have before me your letter of July 20 on the subject of the covenant against contingent fee operators which the President has directed to be inserted in all Government contracts. You ask how far the requirement of the insertion of this covenant is to be observed in certain circumstances arising in the coal industry, and what its effect will be if so inserted. I have no hesitation in saying that the circumstances set forth in your first, third and fourth paragraphs are within neither the letter nor the spirit of the covenant.

In the second paragraph you ask, "Is the above provision intended to prevent an operator from employing a sales agent on sales of coal to the Government where such sales agent receives as compensation for his services either a fixed price per ton or a percentage of the selling price?"

The letter of the covenant and the President's request is broad enough unquestionably to include such a situation, but it is clear, when the attendant circumstances are considered, that the situation is not within the spirit either of the President's order or of the covenant. Rules and regulations have been promulgated relative to licenses for the distribution of coal and coke by which the compensation to be paid to sales agents is rigidly controlled. Manifestly, it was not the intention of the President in requesting the insertion of this covenant to modify the policy or affect these rules and regulations. The situation in the coal industry is, therefore, outside the mischief which the covenant was intended to cure, and unquestionably outside the President's intent.

It is my opinion, therefore, that the covenant has no relation to any of the situations set forth in your letter.

Prices Announced for Alabama Coal

Prices covering operations in Alabama have been announced by the Fuel Administration. The determination of these prices has required arduous work and has been established on seams rather than by districts. The prices for run-of-mine, prepared sizes and screenings respectively are as follows: Big Seam group, $2, $2.30 and $1.95; Cahaba group, $3, $3.30 and $2.65; Pratt group, $2.40, $2.60 and $2; Helena and Harkness seams, $2.45, $2.75 and $2.25; Climax seam, $4.15, $4.40 and $2.05. The prices do not include the 45c. which may be added by those conforming to the Washington wage agreement.

Assistant Fuel Administrator Appointed for New York State

Delos W. Cooke, fuel administrator for New York State, has announced the appointment of Mercer P. Moseley as assistant fuel administrator. Mr. Moseley, who was born in Pamplin, Va., 37 years ago, is vice president of the American Exchange National Bank. He was at one time president and publisher of the *New York Commercial*. Mr. Moseley is a member of the Bankers' Club, Richmond County Country Club and a trustee of the Staten Island Hospital.

The offices of Mr. Cooke will be removed about Sept. 1 from 61 Broadway to Fifth Avenue and 21st Street.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The continued fall in the tonnage week by week has been extremely disconcerting, the only glint of satisfaction being that it occurred in like measure last year and then came to an end before the close of September. If the parallelism between this year and last continues we may look for the maintenance of the present tonnage till the winter arrives.

But this is not enough to save the desperate coal situation. We must do more than maintain our lead on last year, and a careful investigation of the reason for failure must be made. In the summation for Aug. 10 the car shortage is credited with 9.8 per cent., labor shortage and strikes with 4.0 per cent., mine disability with 4.2 per cent., no market with 0.4 per cent. and all other causes with 1.9 per cent.

The railroad inabilities hardly find place in a labor review. Yet in passing it will be permissible to condemn an economy which did not find funds for the complete revitalization of the railroads. On the railroads depend the manufacture of steel, and, consequently, the necessities of the railroads come ahead of the muntion needs. Transportation is a basal industry in a more real sense than the steel industry, and any material it needs to develop it from a a condition of inability to one of adequacy should be preferentially provided.

Reasons for Excessive Mine Disability

An important shortage, however, arises, as has been shown, from mine disability. The United States Geological Survey does not analyze this deficiency. It is not clear whether it arises from lack of material or from lack of men to keep things in repair or from an unwillingness of day hands to work overtime. When it is hard to obtain men after hours it is necessary to shut down the plant and make repairs which at other times could be made at night. But there may be another cause for disability. We are arriving at a period of the year when the streams are low and shortages of water occur, making the running of boilers difficult. Low water also results in increasing the acidity of the streams because it increases the percentage of mine effluent to total stream flow. This often causes the boilers to give trouble, whereas in high water the boilers run without much care.

The mine disability in northern and central Ohio ran up to 13.1 per cent. in the week ending Aug. 10; in Illinois it was 7.4 per cent, in Indiana 6.8 per cent and Iowa 5.6 per cent. A shortage of orders has appeared in Kansas and Missouri, Oklahoma and Arkansas, on the Western and Pacific coast, Iowa and the Rocky Mountain region. The lack of orders is most keenly felt in the Rocky Mountain district where the shortage is 6 per cent. of capacity.

Will End Bonuses and Leave Wages Alone

Dr. Garfield has not been convinced by the presentation made by the United Mine Workers in favor of increased wages. Where bonuses are being paid he is of the opinion that the price of coal should be cut till the practice is eliminated. He has no intention of raising wages elsewhere to bring them up to the bonus level.

Much bitterness has arisen from the temperance agitation. The *United Mine Workers Journal* says: "The fact that the coal miners of America are producing more coal than ever before in the history of the industry, and doing this with a greatly reduced force of miners, is the best answer to the charge of the National Coal Association that liquor drinking by miners is retarding coal production."

Of course, it does not prove anything of the sort. It only proves that some men are doing more than they did before and that the mines are working more steadily. Despite the showing quoted drunkennness may be more or less frequent and general. There is reason to believe that the quality of the liquor drunk is lower than it has been in the past. From all appearances where the miners are mostly natives, the war is having a steadying effect. An all-American mine is less apt to be troubled by drunkenness than one with a large number of foreigners. It is in the American strongholds like Kentucky, Virginia, and Rimersburg, Penn., that the men are working on holidays and giving their money to the Red Cross. Men who deliberately give up their holidays give of their best every day of the week.

Rimersburg Works for Red Cross on Labor Day

At Rimersburg, a little village on the Sligo branch of the Allegheny Valley, Clarion County, the miners have resolved to work on Labor Day, Sept. 2, for the American Red Cross, to which organization their wages will be paid. The officials of the Acme Gas Coal Co., the Lehner Coal Co., and the Halmer Coal Co. have agreed to turn over to the same orginzation 50 per cent. of their pay rolls for Labor Day. That should give the mine workers an incentive to put out a good tonnage.

It is different near Pittsburgh. There, it was questionable for a time whether one day would satisfy the mine workers. They wanted to have their annual meeting at Kennywood Park on Aug. 31 and to celebrate Labor Day on Sept. 2 into the bargain. The park was leased, badges were ordered and advertising printed, but finally it was arranged to hold the meeting concurrently with Labor Day. Had the miners insisted on observing Saturday, Aug. 31, they would have laid themselves open to a fine of $1 apiece, and there was every disposition on the part of the operators and federal authorities to impose it. The union leaders were against the double celebration. Some operators were asking that the electric power be shut off the park on the Saturday of the miners' celebration. There was much excitement and anxiety, but after all the patriotism of the mine workers and their sense of obligation under their contract had the upper hand.

Hard Coalers Seeking Bituminous Wage Rates

In the anthracite region many of the drivers are convinced that they should make the same wage as the men of their occupations in the bituminous mines. The drivers of the Susquehanna Collieries Co. at Williamstown colliery, near Lykens, Penn., decided Aug. 17 that they would not go to work until their pay of $3.11 a day was increased by $1.89 to the $5 rate in force in soft coal mines

On Aug. 19 the 1400 mine workers who were thrown out of work decided to cast in their lot with the drivers and not to return to work till their demands were granted. The "outside" men are not making a demand but, of course, they are not working. They recognize that their position is the same as that of the drivers, and they intend to strike as soon as the drivers "get theirs." As there are 300 of them the mine will inevitably be laid idle, when, of course, there will be some others who will be seeking a readjustment.

On Aug. 14 twenty mine workers at the Smith colliery of the Wilkes-Barre Anthracite Co. refused to pay union dues, and the other mine workers refused to work with them. The strike only lasted a day, the men leaving the matter to the district officers.

A commission has shown that Alberta mine workers have to pay 25c. per day more for living expenses now than in April and consequently, as they have a sliding scale which is based on the cost of living, they will receive an increase in wage of 25c. per day to date from Aug. 1.

Williamson Miners Say "Work or Fight"

The members of the United Mine Workers of America in Williamson County, a leading coal producer in southern Illinois, have agreed that at each mine two men, one selected by the company and one selected by the mine workers, shall form a committee to keep a record of the miners who leave the mine early in the afternoon and of those who, without sufficient excuse, do not "show up for work." This is an action of the mine workers themselves. Every man must "work or fight," and the men of Williamson County are of opinion that it means something more than "have a working place or fight." They take it as it was meant—literally and without a quibble. They feel that the miner should put in the 8-hour maximum in the mines and produce all the coal he can in that time.

Even Engineers' Regiment Rejects Miners

Capt. William E. Mitchell, in charge of the Central Illinois recruiting district, with headquarters at Peoria, has sent out orders that hereafter no men connected in any way with the coal-mining industry are to be permitted to enlist. Recruiting officers are also directed not to enlist men who have recently resigned positions in the industry. Each case of a man who claims to have severed his connection with a coal company, with no intention of resuming such occupation, is to be carefully investigated by communication with the former employer and if it appears that the applicant has left such employment without consent of the employer, he is to be rejected. If a man has been employed in or about a coal mine he is not necessarily barred, but mine workers are not to be permitted to enlist if they have quit such employment with that intention. Information has also been received that no more miners are to be enlisted even in the Twenty-seventh Engineers, all the recruits in which up to this time have been miners with not less than three years' experience.

Miners Fine Man for Speaking German

Disorders in the name of loyalty continue to occur sporadically in the Illinois fields, despite President Wilson's appeal for an abatement of mob violence during the war. Charles A. Karch, until recently district attorney at East St. Louis, went to Campbell Hill, in Jackson County, the other day, to act as attorney for William Schatte, charged with speaking German to his father in front of his home. The mayor of Campbell Hill had recently issued a proclamation forbidding German speech, following a visit of a delegation of miners from Willisville, five miles distant, who threatened to clean up the town.

State's Attorney Otis Glenn of Murphysboro prosecuted the case, although there was no charge that a state law had been violated. A delegation of about 200 miners from Willisville attended the trial. According to Karch, Glenn, in his address, said that there ought to be a riot if Schatte was not convicted. The justice fined Schatte $50. Karch, anticipating such a result and desiring to get the case into a court of record, produced a bondsman and began preparing an appeal. The miners gathered outside and sent in word that neither Karch nor his client should leave the building until the fine was paid. Glenn and an army officer made speeches asking for order, but Karch considered it prudent to have his client pay the fine. Karch will call the attention of the Federal authorities to the occurrence.

District Attorney E. C. Knotts of Springfield, Ill., has ordered the officials of Madison County to take action against the members of a mob which recently compelled Alois Otradowitz, an Austrian, to kiss the flag and leave the town. The State's Attorney has promised to call a special grand jury. Evidence against the mob members has been gathered by Julius Rosin, chief of the United States Bureau of Investigation. Harry Fishback, vice-president of the United Mine Workers of Illinois, has been coöperating with the Federal officials. It was in this county, at Collinsville, that Robert P. Prager was lynched.

Farrington Sidesteps Prohibition

Frank Farrington, president of the United Mine Workers of America in the Illinois district, wants it understood that he does not concur with the National Coal Association in its advocacy of nation-wide prohibition for the duration of the war. In a telegram to Fuel Administrator Garfield he says: "Press dispatches implying that I had conferred with President Wilson, with you, and with the National Coal Association, and that I had urged nation-wide prohibition, and statements that I am in favor of the project of a so-called industrial army are untrue. I deny that the production of coal in Illinois is materially reduced by the indulgence in intoxicants of the miners of this state, and I protest against such an implication as being an unwarranted indictment against their intelligence, dignity and patriotism.

"The contributions of the miners to the Red Cross, their purchases of Liberty Bonds and Thrift Stamps, and also their active and effective suppression of seditious conduct and disloyal utterances in the mining communities throughout the state, and their insistence that all men subject to military duty go to the front, give assurance that they will measure up to any requirements made known to them by the Government. We hold the Illinois miners are just as patriotic as are the men employed in the shipbuilding industry, munition plants and other industries engaged in the manufacture of war supplies, and if a line of contact is established between representatives of the Government and the men who mine the coal such as will enable them to know what is required of them, their sense of duty is such that they will meet every obligation.

"The proposed plan for an industrial army with badges and service stripes will not appeal to the manly sense of patriotism manifested by our men. A campaign of education based on direct statements to the miners by the President of the United States and the Fuel Administrator, conveying to the men the truth that their industry in the mines is as vital to the nation and as honorable as military service is all that is necessary and is much more expedient than the proposed project. I pledge for myself and my executive board members that we will carry such a message into every mining community in Illinois."

Secretary Nesbitt of the Illinois district joins with Frank Farrington saying: "When the Coal Operators' Association attempts to lay the blame of coal shortage to the miners because of the effects of booze then they are doing the very thing that may disturb the harmony that has existed in the coal industry for the past months. They are stroking the fur the wrong way as usual and if coal production is not kept up to the maximum the coal operators will be to blame."

Thomas T. Brewster, president of the Coal Operators' Association of the Fifth and Ninth Districts of Illinois, has wired to Administrator Garfield that he concurs in Farrington's telegram. He states that he expressed substantially the same views to Mr. Neale during a conference in Washington last week. While Brewster sends the telegram in the name of the association, it is certain that he does not fairly represent the views of the members of the association or of the Illinois operators generally.

Aside from their personal views on the question of prohibition they are practically unanimous in the opinion that saloons are a decided detriment to coal production.

John Henderson, of St. Louis, Mo., president of the West Virginia Coal Co., of Marion, Ill., says he fully approves the action of the association. "I am not a prohibitionist," he says, "but saloons, whether at the mines or a hundred miles away, hurt coal production. The coal states, at least, should be dry. I believe the operators are unanimous on this question. There is no argument in favor of the saloon in connection with the mining industry that I can conceive of. Saloons are a detriment not only to the mines but to any class of work."

The Trades and Labor Assembly of Belleville, Ill., at its last meeting, adopted a resolution in opposition to nation-wide prohibition and in protest against Administrator Garfield's order that no more coal is to be supplied to breweries after their present supply of raw material has been used. Belleville is a brewery center.

Would Have Extra Pay for Overtime Work

Anxious to hasten a favorable decision on the wage demands which their leaders have placed in the hands of the Government, the employees of the G. B. Markle Coal Co. have refused to work more than 8 hours daily, thus violating the express provisions of their contract, which reads: "If, because of breakdowns, repairs or the requirements of transportation or other causes essential to efficient operation, it is found necessary to extend the normal workday of any employee, or any class of employees, the operator may do so, at his option, paying for overtime a proportionate rate per hour as determined from the rates established under Section I hereof."

Despite this clear requirement, no breakdowns are repaired at the G. B. Markle mines after the 8-hour limit and none, the men say, will be repaired till time and a half is given for overtime and double time for Sunday. The Oakdale local is foremost in agitating for this new provision. Many men had been working overtime and they still desire to do so but they are threatened with expulsion from the union if they do not consent to violate the rule which the union itself approved in representative session. These day workers found the additional pay of no little service in meeting the payments on their Liberty Bonds, but now they are deprived of that source of income. However, loss of tonnage resultant on the delay in repair work is more harmful than the delay in payment for Liberty Bonds. Repairs can be effected more readily in the overtime hours than when the mine is running, and, in fact, many repairs can be made only at such hours.

Nationalities in Clearfield District

The number of miners in the Clearfield, or Central Pennsylvania, or No. 2 union district of the bituminous regions of Pennsylvania, increased in 1917 over 1916, the gain being in Americans. The American influx not only made up for the small loss incurred in the number of foreign mine workers, which totaled 342 men, but it increased also the number of mine workers by 4,772; for as will be seen the total number of American mine workers increased by 5114.

Order	Nationality	1916	1917	+ Increase or — Decrease
1	American	20,555	25,669	+5,114
2	Italian and Tyrolean	9,386	9,039	— 347
3	Slavonian	8,779	7,985	— 794
4	Polish	6,561	5,669	— 892
5	Austrian	3,121	4,527	+1,406
6	Hungarian, or Magyar	3,752	3,913	+ 161
7	Russian	1,953	2,199	+ 246
8	English	1,845	1,491	— 354
9	Swedish	1,232	1,362	+ 130
10	Scotch	1,161	1,118	— 43
11	Irish	963	1,030	+ 67
12	German	1,262	1,021	— 241
13	Croatian or Horwat	707	726	+ 19
14	Lithuanian	625	718	+ 93
15	Welsh	462	522	+ 60
16	French	261	324	+ 63
17	Greek	335	305	— 30
18	Belgian	253	289	+ 36
19	Rumanian	25	81	+ 56
20	Finnish	94	60	— 34
21	Canadian	7	49	+ 42
22	Danish	55	38	— 17
23	Spanish	.....	36	+ 36
24	Montenegrin	4	31	+ 27
25	Bohemian	80	27	— 53
26	Syrian	14	15	+ 1
27	Mexican	.....	11	+ 11
28	Serbian	.....	6	+ 6
29	Swiss	.....	3	+ 3
	Total	63,492	68,264	+ 4,772

The gross increase is 7.51 per cent. We have arranged the nationalities in the order in which they stood in 1917. The representations of some so-called "enemy alien countries" have decreased and others have increased. The Germans have decreased considerably; the Austrians and the Hungarians have increased, as have also the Croatians and Horwats. The neutral countries have increased in numbers somewhat, Russia (neutral only part of 1917) leading with 246, Sweden with 130, Lithuania (neutral only part of 1917) with 93, Rumania (neutral only part of 1917) with 56, Spain with 36, Mexico with 11, and Switzerland with 3.

Finland (also neutral only part of 1917) is an exception, for it was represented by 34 less men than in 916. These men doubtless went back to take part in the fights succeeding the declaration of Finnish independence. Denmark, strange to say, lost 17 men. The people of allied nationalities, and with them we include the Czecho-Slovaks, Poles and Syrians, have in most cases decreased in numbers owing to recruiting. The Polish loss led with 892. The Slavonian loss was 794; the English, 354; the Italian, 347; the Bohemian, 53; the Scotch, 43; and the Greek, 30. The British and Italian losses would have been greater, but large drafts in earlier years made a large draft in 1917 unlikely.

Some of the allied nations had increased representation. Principal among these were the Irish, 67; French, 63; Welsh, 60; Canadian, 42; Belgian, 36; Montenegrin, 27; Serbian, 6, and Syrian, 1.

The figures on which the table is based were prepared by Charles O'Neill, production manager of the district in question and secretary of the Central Pennsylvania Bituminous Coal Producers' Association.

Missouri Men Again Ask "To Be Shown"

The patriotic tour arranged by the miners and the Southwestern Interstate Coal Operators' Association, to stimulate production, has not been an unqualified success. Reports indicate that there was a decline in production, an increase in number of days of layoff, and an increase in grievances, in many districts, immediately following the tour. Commissioner W. L. A. Johnson, other commissioners, the officers of the miners' district associations, and a maimed soldier back from the front, spoke in all at 25 meetings in the mining towns of Missouri, Kansas and Arkansas, Mr. Johnson personally attending about a dozen of the meetings.

The representatives of the operators pledged such management of the mines that the largest opportunity for production would be provided, and asked that miners work as nearly as possible eight hours every day. Miners' representatives pledged a maximum of work. The soldier urged support of the boys at the front. While the spirit of loyalty may have been aroused, one incidental result of the tour was the inspiration to make a closer inspection of the conditions in the mine so as to clear the way for possible complaints by the miners.

In Missouri, especially, a flood of suggestions came to state fuel administration headquarters, and to other parties, as to how the mines could be made to produce more largely, by the addition of this or that equipment, or by such and such changes. Lieutenant Governor Crossley, fuel administrator, held a meeting of representatives of operators and miners, at which many of these suggestions were discussed. The meeting got nowhere; it was explained that one of the main factors in the patriotic effort now being made is the better use of present equipment to gain a larger production—that industry must increase its help to win the war, and not put any more burdens on manufacturing, transportation or financing.

Indiana's First President To Be Honored

Edward Stewart, the president of the United Mine Workers of America, in the State of Indiana, and William Mitchell, the secretary for the same organization in that state, with W. B. Van Horn, international board member, have had a long search at the cemeteries in the vicinity of Harrisburg, Ill., for the grave of Gardner Knight, the first president of the United Mine Workers of Indiana. He left that state in 1906 and located at Collinsville, Ill., and shortly after moved to Harrisburg. On May 25, 1907, he was working with his "buddy" when the latter stepped out of the room. On returning the "buddy" found the dead body of Knight. Apparently he had dropped dead. The Indiana mine workers have located the body in the City Cemetery of Harrisburg and will erect a monument in honor of this, their first, president.

Schemes Which Cripple War Work

FADDISTS are always busy, but at no time were they ever more completely at home than during this world war. The Government is taking over all kinds of utilities and starting all manner of new projects, and the faddists now have a chance to urge their plans on politicians and visionaries who are spending other people's money and not their own, and who are therefore not personally interested in the outcome.

Some of the schemes, however, are good enough in their way. The one proposed by Representative Thetus W. Sims of Tennessee in his bill presented Aug. 19 in the House has something to commend it. This journal and many others long ago expressed the belief that the soft-coal companies should deliver either power or gas to the public and not bituminous coal.

Railroads use altogether too much coal in the work of delivery. The estimate of Dr. Garfield for the bituminous coal likely to be used by the railroads during the present coal year 1918-1919 was (as we showed last week) 26.53 per cent. of the whole bituminous coal cutput. But that figure should be written somewhat differently; it is 27.05 per cent. of the coal delivered to the railroad, for it is the net percentage which really counts. Of course, only a portion of the entire railroad freightage is coal. It is said to be 16 per cent. of the whole. As coal travels in bulk—in full car-load and even in full train-load lots—it is probable that the fuel consumed in coal freightage is less than the coal used in the freightage of an equal weight of miscellaneous material. Overlooking that fact, the percentage of coal used in coal freightage would be 4.33 per cent. of the net amount of coal which leaves the mining towns in which it is produced. This percentage is roughly 26,560,000 tons.

Clearly, it is well worth the saving and should be saved. The year when the world has a war on its hands, however, is not the time to go to work to save it; for the labor of putting the saving into operation is too great and the time needed for completing any new plan of distribution too long. It would be far better to build up the railroads to a point of greater efficiency. More railroad cars, sidings and terminals, and more storage yards at mines are needed.

Representative Sims wants the Government to buy power plants, to build others at the mouths of coal mines and to assist in financing such operations. Refuse coal is to be used and the power supplied to factories by electric current. Some believe that with electrification of the railroads we could save two-thirds of the coal now used in railroad operation. Whether that is true remains to be seen, but it is certain that it should not be done till the war is at an end.

Yet as a war measure the mine-to-factory plan is not nearly so chimerical as are the water-power schemes. The Muscle Shoals water-power plan so enthusiastically hailed when the war commenced has already been laid on the shelf till after the war, and the ammonia and cyanamid will be made for the present solely by steam power. Electrification of the railroads must similarly be delayed.

A reconstruction period from a mechanical point of view is quite likely to follow the war, and remarkable changes will occur. The faddists want the Government to attempt them now, knowing that it will be hard to get private capital to plunge in heavily after the war in face of the immense risks to be run and in face of the fact that, no matter how much the public profits, the dividend of the power-plant builder is likely to be strictly limited by Federal and state regulation.

Often it seems that the Government must ultimately do the work. A gamble in which the gambler runs a good chance to gain 5 per cent. and a better chance to lose 100 per cent. is a gamble that does not commend itself to anyone. The tendency is all toward Government ownership, not because it is efficient or desirable, but because with regulated profits business ventures are either as good as investments in Government bonds or complete failures. Of course, as soon as the profit from a Government bond is the best profit available, the tendency will be toward buying Government bonds instead of investing in so-called securities that are allowed to yield at best no more than bonds and are quite apt to be complete failures.

If new developments when made under private ownership are to be so scrupulously regulated, they will have to be made by the Government if they are made at all. We shall be willing individually to invest in the extension and continuance of *recognized* industries which afford a certainty of a given annual income, but such risky innovations as are likely to be regulated we will put up to Uncle Sam. Perhaps he will save money for the public on some of them and the public will stand the losses made in the others. He will probably learn after a while that to have a balanced account he must have some big gains to replace his big losses. He must run some business at a vast profit so as to find the wherewithal to repay the losses on the Panama Canal and like unprofitable developments.

But to return to the main proposition, such mammoth schemes of dubious value must not be allowed to cripple war work. The immediate needs stand first. Labor may have to be used for the temporary alleviations of the transportation shortage. That labor may possibly be partly wasted, but there will be less waste than takes place every day on the battlefield; and the sooner the war is over the sooner we can cut out these and all other wastes.

We shall do ill to stagnate our industries and to defeat our national purposes by attempting during the war any basal and tedious reconstruction of old and tried methods, however faulty; for if we do so, we run the risk of repeating the mistake of the earlier authorities

in charge of our aircraft production, who in indecision and in futile experimentation wasted full sixteen months of incalculably valuable time.

Our methods are not the best that can be devised, and they never will be. We shall have reached an undesirable stage in development when we no longer see vistas of promise ahead as the result of diligent reconstruction. Science progresses like nature, by the death of the older forms. The decay of old models and methods serves to form the humus for new developments. As life builds on life, so invention builds on invention.

But we can readily destroy more rapidly than we can rebuild. We can be too enthusiastic in our renovations and at no time is there greater danger of such foolishness than during a war, which reveals the condition while removing or greatly restricting the opportunity to correct it.

After-the-War Wage Arrangements

IN AN open market, and with runaway production, wages determine prices. So the margin between price of product and cost of production will be unchanged by a change in wages. It may be plus or minus. All will depend on the fierceness of competition and the degree of intelligence of the competitors.

As wages under normal conditions determine prices, it is no advantage for operators to lower wages. Wages should therefore not be lowered after the war. In a certain key district, say the Pittsburgh region, wages should be fixed to increase with cost of living, but not to decrease with it should it decrease. The cost of living should be determined every six months by a competent authority and adjustment made to accord. In other regions than the key region, the increases, if any, in the rate of mining in cents per ton granted in the key region should be imitated exactly in cents per ton so as to preserve the industrial equilibrium.

Where the price of powder to the miner has remained fixed regardless of the price to the operator, it should remain unchanged after the war. When the price of powder goes down the operator will be entitled to the saving in cost thus made possible. He has continuously met the loss due to the rise in price and no one should begrudge him the adjustment, especially as it will affect all about equally and therefore will not promise a profit to any one; for where all gain, the price reflects that fact.

House rents should be lifted to a profitable figure at the next adjustment. The cost of rent should be figured in with the cost of living at the higher rent provided and the wage adjusted to conform with the cost of living thus determined unless the change would result in a reduction of wage which is not to be considered.

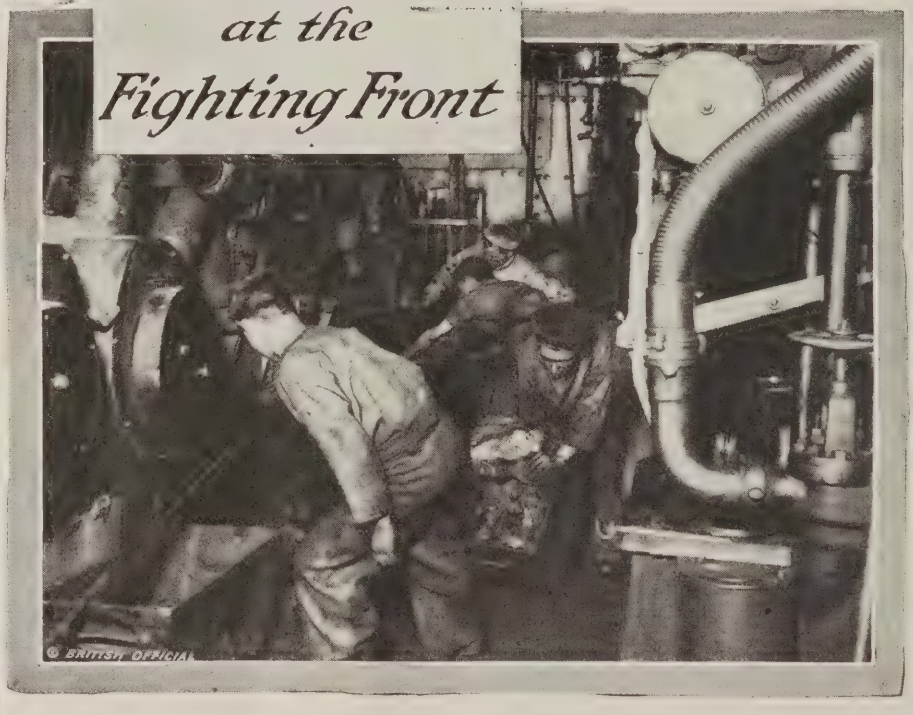
Men who cannot read and write English should be required to give one hour's attendance without pay three days a week at a school for teaching the English language. A fee should be charged for this training high enough to provide for a really competent teacher and for adequate equipment.

When wages are next raised the increase determined as being fair should be doubled and that larger increase applied only to the half year which includes the winter season, so as to make the demand for coal more equal. Any further increase to contract men which cost of living may ultimately provide should be in the form of day wages and not contract wages. This will form an incentive and award to the operator who gives his men an opportunity to do a good day's labor and to see that every man does a full day's work.

Most of these changes have been advocated before at different times. They are good plans whenever they may be put in operation, after the war or later. Working under them the miner will feel that his interests are safeguarded, that the principles of justice rule and not the caprice of the operator, and it will be clear to him that if he strikes for more pay he strikes not against the operator, but for an unfair proportion of the national output. It will be plain that his strike is directed not against his immediate employer but against his remote employer, the other working men known in general as the public.

Strikes, like war, must ultimately be cast into the discard. The fundamentals of wage agreements should somehow be written. We need a Grotius to write the laws of industrial peace, perhaps for one industry only, but later for all industries. Must all justice—justice to employer and justice to employee—be battled for? Can not the fair thing be written in perennial brass so that it may not be doubted? Of course, a few matters will for a while be debatable. We shall have higher justice as we have higher mathematics. But the simple, basal rules may we not now write, read and follow and so avoid those frequent jars which destroy the poise of our industrial life. But to secure these fundamentals we all need economic education. We need above all to let the workman cut his eye teeth. Induce the workingman to accumulate stock or a property and he will have a clearer light on the necessities of capital.

Shall We Seek More or Better Mines?



SEVERAL of the small operators, some of them new to that capacity, just barely start operation before they are importuned to go into another venture. They are not out of debt on the plant they are running; they do not have it in good working order; they lack the needful equipment—but the new venture looks good. Instead of riding one sound and speedy horse, therefore, they drag along on two sorry nags neither of which is a credit to the owner. This manner of playing operator does not pay. After the war ends and the usual set back comes, these men with their badly equipped mines will find it impossible to operate them profitably. If they had stood by the one mine, nursed it, watched it, equipped it, it would have done more than the two mines will do and a year after the war there will be plenty of opportunity to load up at sales and foreclosures with plants of the overventuresome.

But we do not need to rely on self-interest alone, which might in cases be hard to prove, for it can be shown that it is not a patriotic act to leave a half-opened mine to lag and do uncertain, irregular work in order that we may open another mine without any greater prospect of efficient and orderly operation. A good mine put in by the financially competent is another proposition. The reference is to the smaller mines, which are differentiated from wagon mines by the possession of, or the aspiration for, a railroad switch.

Here's Where Your Coal is at the Fighting Front

Coal passers and stokers who use our coal in the narrow passageways of a battleship, toiling before blazing hot fires, have a far more burdensome existence than those who mine and handle the coal in the cool atmosphere of the ordinary American coal mine.

DISCUSSION BY READERS

Dealing with Slackers in Mines

Letter No. 1—I have been deeply impressed, recently, in reading certain references to the loyalty of the French coal miners, who are face to face with the severe conditions imposed on them by reason of the war in their own country. I read these comments, in the French newspapers sent to me, with great interest, and cannot help but contrast the situation there with that in this country. The American miner, for the most part, feels his responsibility for the winning of the war. Never before has he had the same opportunity to make such big wages. Nevertheless, there are many slackers among them.

Numerous suggestions have been made by *Coal Age* writers, in discussing the relation of the miner to the war and the mining situation in general. In order to increase the production of coal, some have suggested longer working hours. I agree, however, with those who contend that a longer working day will not increase the output of the mine. The trouble is not in the number of hours the miner works. He can produce all the coal that is required if the cars are on hand to load. The shortage of cars is the one great difficulty to be overcome.

Next to the question of car supply is that of holding miners regularly in their places. There would be no slackers if American miners believed, as do the French, that there is as much heroism in digging coal as in fighting at the front. In our efforts to eliminate slackers from the mine, we must impress upon them the truth of heroic service beneath the ground.

What Conscription of Mines Should Mean

While I believe in the conscription of miners, it would be of a different kind from that imposed by the draft law. My idea of the conscription of the miner would leave him free to perform his daily tasks according to his usual custom, with the exception that his work would be under the strict discipline of the Government, with a view of increasing the tonnage per man, and making the production of coal equal to the demand.

This conscription would be somewhat along the lines of the employment of a government inspector, as suggested by Thomas Hogarth, June 29, p. 1208. Another has suggested the wearing of a "service button"; and still another, keeping tab on the work of all miners by "a system of index cards" that would show where and how long the man had worked and with what satisfaction to the company.

In this regard, my idea would be that mine superintendents and foremen should act under the authority of the Government and report those miners who are slack in the performance of their work, for investigation by the government inspector. As someone has said, a soldier disobedient to orders is punished, and I agree that a suitable punishment should be inflicted on idle mine workers, including such as do not work industriously and show the best that is in them.

All workers of this class are *slackers* and, in retarding the production of coal, they retard all industrial work by their failure to produce to the extent of their ability. At present, no penalty is imposed or any fine exacted, and there is no way of reaching this class of slackers in the mines. They cannot be fined and yet they obstruct the work continually.

There is no question, in my mind, but that the miners can produce all the coal required if they will do their utmost. It is possible for the organization of miners to impose the obligation of steady work on their own members and thereby avoid any action by the Government; but, in any event, let us all stay on the job with the same faithfulness as displayed by our brothers in France.

GASTON LIBIEZ.

Cedar Point, Ill.

Justice to the Miner

Letter No. 1—Out of fairness to the many honest mine workers, who form a large majority of the miners employed in the anthracite region, I feel impelled to offer a few comments regarding the position in which these workers have been placed by reason of many misleading statements recently published.

Only last week, an article headed "Hun Propaganda Trying to Injure Anthracite Industry" received wide circulation in the daily papers. The article referred to a meeting of mine workers that was held in Wilkes-Barre, Aug. 6, when a resolution was passed drawing the attention of the coal operators to the increasingly hard living conditions of their employees. Referring to this resolution, the article denied that the conditions of the miners were hard, stating that such claims were false. The claims, however, are based on facts that cannot be denied.

How War Affects Conditions Underground

Such is the urgency of the work underground that not only is the miner often compelled to work under dangerous conditions for the lack of needed supplies, but, in addition to mining and loading his own coal, he must often finish out his day's labor by carrying rails, track ties, props and brattice boards from one place to another. These facts are proof that the statements referred to were correct and that the conditions under which the miners are forced to labor are increasingly hard.

While I am not in accord with the meeting, as it was held, I feel justified in defending the many men who attended with an honest purpose to secure a fair deal. The loyalty of the anthracite miners cannot be disputed. They have made home secrifices to buy Liberty Bonds, and subscribed liberally to the Red-Cross drives. Many of them are working 35 and 45 shifts a month, because of the urgent demand of the country for coal.

While it is undoubtedly true that there were some present at the meeting, Aug. 6, whose loyalty would not bear the searchlight of criticism, the large majority of the men who attended met to arrange in regard to the best way of presenting their case for the consideration of the Federal Fuel Administration. The fact of the matter is that, not only are the ranks of the miners being depleted by the draft and by voluntary enlistments, but the wages that can be earned in other war industries have been advanced in much greater proportion than those of the coal miner.

Mining Wages Lower Than What Can Be Earned in Other Industries

The wages paid mine workers are such as not only to offer no attraction for labor to enter the mines, but call for much sacrifice on the part of many loyal miners who are feeling the injustice accorded them by reason of the urgency of the country's need. Miners are made to feel the injustice of their position all the more because of the slander of the daily press, which is calculated to fill the public minds with the thought that the average coal miner is a "slacker," whereas no industrial worker is more loyal than the miner.

In closing, let me say that such untruthful statements in the public press cannot fail to lead I. W. W. organizers to think that the anthracite fields promise a good harvest for them, and cause them to increase their efforts to strengthen themselves in this region. The principles of that organization are un-American and it is the duty of every true and loyal worker to keep all such out of the mines. J. P. G.

Wilkes-Barre, Penn.

Letter No. 2—Referring to the announcement in *Coal Age*, July 25, p. 196, that the coal production for the week ending July 13 was almost 13,250,000 tons, allow me to state that the report of the Fuel Administration at Washington, after mentioning this record production for the week, followed their statement with the remark that "If the miners keep the output of coal up to that figure, there will be no danger of shortage next winter," which is not true if the car supply fails.

In justice to the miner, it is only fair to say that this remark reflects on the great body of miners, as it conveys the impression that the entire responsibility for the production of coal rests on the toilers in the mines. The wording of this official bulletin from Washington allows of but one conclusion, which is that the coal output depends solely on the miner, which is not only wrong in fact but an imputation that questions the patriotism of this body of faithful workers. The flow of coal from the mines does not depend exclusively, or even largely, on the miner.

Railroads Responsible for Coal Shortage

The public should know, as all practical mining men know, that the coal supply for industrial and domestic purposes, now and next winter, is and will be determined by the ability of the Railroad Administration to supply the needed cars for its shipment to market. A shortage of cars on the siding always means an idle mine and hundreds of idle miners who are unable to perform their daily tasks.

In the discussion of this question, too much has been said in regard to the responsibility resting on the miner, and too little emphasis has been placed on the greater responsibility resting on the Railroad Administration, whose task it is to supply the needed cars. It is a mistake to attempt to conceal this most vital fact bearing on the production of coal.

Let me say, here, that there would not have been a coal famine last winter had it not been for the shortage of railroad cars at the mines. It may be true that the administration is not wholly to blame for this failure of car supply, which may arise from weather conditions, or their inability to build the necessary equipment; but that is no reason why the responsibility for coal shortage should be laid on the backs of the willing miners.

There is but one way to insure a constant and adequate output of coal, and that is to give the miners plenty of cars in the mines and on the railroad tracks so that there will be no delay in loading coal either at the working face or on the tracks for shipment. Give the miners the cars, and they will attend to getting out the coal. Let the Government do its part and the miners will not be found wanting. Fairness to all demands that the Government assume its share of responsibility for each week's production of coal.

Mammoth, Penn. PATRIOT.

Letter No. 3—The numerous references to the miner that one reads today, including some statements that reflect on his loyalty in the present crisis, have put these thoughts running in my head, after reading the verses of Rufus T. Strohm, *Coal Age*, Aug. 1, p. 201.

I always read the verses in Coal Age *as they come,*
And Mr. Strohm has sent some stirring lines;
But what he said about us has almost struck me dumb,
For I've spent some little time around the mines.
Of course we have some slackers, like every other trade,
But that should not condemn us as a whole;
For we know we are responsible for every gun that's made
And we shall not lose the war for lack of coal.

He surely does not know us and more knowledge he should seek,
For his lack of information must be plain;
When he says the miner's time card shows but thirty hours a week
I feel that on our name he casts a stain.
Each day about at daybreak, we go down into the pit,
Just guided by the glimmer of a lamp,
And work our full eight hours, before it's time to quit
And turn our faces to the homeward tramp.

No one can now accuse us—if we're given half a chance—
Of doing anything to blush with shame;
For, if we are not fighting with the boys across in France,
We know that we are with them in the game.
We do not seek for glory, but still we do not feel
Like taking kicks we really don't deserve;
We only ask fair treatment, a square and honest deal,
For what we've shown of loyalty and nerve.

No matter how we're treated or what the papers say,
We still intend to do our little bit,
For every shot that's fired by the boys in France, today,
Is provided by the miners in the pit;
Yet we'll give them all the glory and let them have the praise
For what they're doing and for what they've done,
But we'll claim a little credit, in these stern and trying days,
For doing all we can to whip the Hun.

McIntyre, Penn. THOMAS HOGARTH.

(Revised by Michael Bernard.

Americanizing the Foreigner

Letter No. 2—It was with keen appreciation that I read the letter of "Observer," *Coal Age*, July 25, p. 189, as his remarks regarding the manner of dealing with the foreign-born had a trend of optimism seldom manifest in a discussion of that subject by men who have grown up around the mines.

While it is quite true that the writer of that letter offers no suggestion that can be put into effect immediately, yet his underlying thoughts contain a germ of reason that, if fostered, may be turned to good account.

Attitude of the Average Mine Official

The average mine official will, in nine cases out of ten, throw up his hands and say that there is no hope of Americanizing the foreign-born miner. We have all heard men holding high positions, in coal-mining companies, argue that they have tried all possible methods without success. Their belief is firm that the foreign miner will not forsake his native habits and accept the refinements of civilization. Almost without exception, mine officials of American birth claim to have labored in vain to redeem the foreigner.

It is to be much regretted that men are so willing to give up a difficult task What would the world be today had electricians not continued to grapple with problems that long seemed beyond their reach? Everything is possible of accomplishment if we use our brains and stay on the job, and the question of Americanizing the foreigner is no exception to the rule. The man who is willing to let well enough alone is not the man to whom we can look for help in solving this problem. He is a quitter and no quitter ever reached the goal.

Problem Must Be Carefully Studied To Reach Parents through Their Children

The subject is one that must be studied from every angle. Mining men have discussed the question at their meetings, but have never gotten so far as to appoint a committee to study the matter and report. In larger cities where the foreign element predominates, considerable progress has been made by reaching the adult classes through the children, who are taught by capable instructors. This suggests that the schools, in our mining towns, may prove the best avenues of approach when we would reach the miner.

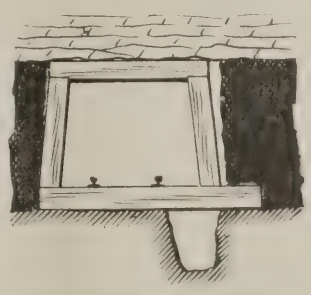
Let the teachers be instructed by mine officials to maintain a high standard of order and cleanliness in the schools. Too often it happens, however, that the school teacher in a mining town or camp is given no opportunity to accomplish possible good, because of a lack of facilities, which those in authority have failed to supply. In many cases, no playgrounds are available, and no effort is made to render the schoolroom and its surroundings attractive.

Again, reason suggests that the adult foreigner cannot be reached as readily through Americans as through people of their own kind who have become Americanized and are in the employ of the company. By living and mingling with their own, this class of workers can exert a greater influence in accomplishing their ends and, by degrees, inject into their friends American ideals and customs.

While, as has been suggested, most foreigners do not appreciate the luxury of a bath as do Americans, yet it is not impossible to teach them the value of water in the improvement of their appearance if not of their health. A teacher by insisting on the children coming to school in clean frocks and with hands and faces washed and hair neatly combed, will do much to cleanse the home and purify the atmosphere where the children live, and ultimately redeem the older members of the family.

Efforts in Other Directions

Much can be done in the way of distributing posters, written in the native language of the people and telling of the services of the company doctor and the aims and purposes of the company officials in maintaining a clean and attractive town. All this, however, will surely fail of accomplishing the desired good when saloons are permitted in the place, and proper steps are not taken to keep the streets and yards free from garbage and other waste.



I am convinced that this subject can be dealt with successfully, and hope that it will be discussed from every viewpoint. Only by this means can good results be obtained. Optimist.

———, Ill.

Blasting a Ditch in a Mine

Letter No. 2—Replying to the inquiry of Geo. Smith, *Coal Age*, June 15, p. 1128, regarding the blasting of a ditch under the mudsills supporting the timber frames in a mine entry, I assume that the 10 x 10-in. timber frames are set 4 ft., center to center, and the 4 x 10-in. mudsills supporting them are laid crosswise of the entry. Under these conditions, if the ditch is to run along the side of the road it would leave the leg of each timber frame, on that side of the road, unsupported.

My suggestion is, in this case, to start the work by using a longer mudsill and hitching one end of this sill into the rib on the side of the entry where the ditch is to be blasted, as shown in the accompanying figure. Like J. W. P., who has discussed this question, Aug. 15, p. 326, I cannot understand why mudsills were used on this hard bottom. However, mudsills will be necessary to give support to the timber frames when the ditch is dug close to the rib, as illustrated in the figure. Let me suggest here that a heavier mudsill should be used than one 4 in. deep, as that would hardly support the pressure on the timbers above the ditch.

DITCHING AN ENTRY

The work of putting in the longer mudsills and resetting the timber frames must be done gradually by placing these halfway between the present frames and sills. The blasting of the ditch, if carefully performed, will probably not disturb the new timbers seriously. It occurs to me, however, that it might be better to drain this section of the mine by blasting a ditch in the parallel entry or air-course, and cutting through the rib for that purpose, if necessary.

I agree with J. W. P. that a ditch is always to be preferred to a siphon wherever it is practicable to make the necessary excavation. My experience has been that siphons are not generally satisfactory, especially where the conditions are such that their regular working is somewhat disturbed. W. H. NOONE.

Thomas, W. Va.

Letter No. 3—Regarding the blasting of a ditch on a slope road where the timber frames rest on mudsills and the bottom is hard, my plan would be to do this work at odd times when the mine is idle, or at night when the track can be lifted and the mudsills taken out, after setting temporary timbers to support the collars while the legs are being reset on the hard bottom.

It does not seem to me that mudsills are at all required in this case and should be discarded. As the timber frames are reset, the ditch can be blasted to the required depth, without disturbing them further. The proposition does not appear to present any serious difficulty.

After the ditch has been blasted to the proper depth the entire length or distance, I would lay tiling in the bottom and fill it over, only leaving holes at suitable distances apart that would allow the drain to be cleaned of any sediment or obstruction that might accumulate. I have seen such a ditch laid and it worked successfully. The road was only 5½ ft. wide and a six-wheel, H. K. Porter steam engine was used to haul the coal on a 24-in. gage track. I prefer the ditch to the siphon suggested. R. W. LIGHTBURN.

Perryopolis, Penn.

Loading Coal at the Face

Letter No. 2—The question of what weight of coal a miner can load in a day is one that is particularly appropriate at the present time, if for no other reason than the rivalry that it may arouse among practical miners to exert their best efforts to excell their fellows in the number of cars they load.

No doubt some miners who are prone to take things leisurely when working at the face will say that the claim set forth in the poster page of *Coal Age*, July 6, p. 29, where a man was said to load an average of 23 tons a day of 8 hours during the month of May, exceeds what is possible. By way of opening the eyes of such disclaimers and in fairness to the man who made this record, I want to say that my personal experience tells me that what would be called "a good miner" can enter his place at the regular time of starting, say 6 a.m. and be home again at 2 p.m., after having loaded from ten to twelve 50-bu. wagons or boxes, and not feel more than ordinarily fatigued.

WHERE CONDITIONS FAVOR THE MINER

The statement just made is based on facts and has reference to mines where conditions are, of course, favorable in every respect, as they are in the mines of the Connellsville coke region. To accomplish these results, however, there must be no delay waiting for smoke to clear or cars to be set. The miner's coal must be cut and shot down ready for loading, and empty cars must be on hand so that the miner can proceed at once with his work. There are times when it will pay the company to have a special timberman set posts, in different working places, so as to relieve the miner of this necessary work, and allow him to devote his whole time to loading his coal.

It is only fair to say that, in a seam of coal like that at Connellsville, where the height of the coal and system of mining are peculiarly advantageous, the miner finds less difficulty in moving about in the performance of his work than in seams where the coal is low and there are other hindrances and difficulties to be overcome.

THE JOLLY GOOD-NATURED FOREMAN

One particular feature that greatly assists the miner and his work is a good light, such as the electric cap lamp or the carbide light. Again, a good-natured foreman can do much to expedite the work of his men by his pleasing manner and his way of jollying men when undertaking a difficult task. The driver must be encouraged with a good word and, if off the track, given a helping hand to put the car back. In other words, the coal-producing spirit must prevail. LUMEN.

Perryopolis, Penn.

Letter No. 3—I have been greatly interested in the question of loading coal at the working face, as this work concerns a large production. First, let me say that it is the duty of every loyal miner to be in his place each working day and not allow one minute of his time to be wasted. Not only must the miner strive to increase his output each day, but he must clean his coal, taking care to throw out bone and other refuse. All coal should be cleaned at the face, as otherwise there is much delay when it is necessary to do this work on the surface.

Where there is the hearty coöperation of all mine officials with their men and the men are given what help is needed and do not have to wait for supplies of timber, tracking, etc., every man will have a disposition to do his best to increase his daily tonnage and load only clean coal. A miner should never be permitted to go home because some little work has not been done in his place. The foreman should make every effort to satisfy his men and keep them at work, since the loss of a ton of coal may mean the life of a soldier.

FAVORITISM AROUSES DISCONTENT OF MINERS

The Fuel Administration can do much to keep things moving smoothly at the mines, by showing no favor and treating every mine alike. When the government inspector shows a disposition to condemn coal loaded at a small mine, because it contains some refuse mixed with the coal, while he passes much of the same kind of coal at a larger mine, the miners cannot be blamed for being dissatisfied, and trouble is the result.

Discrimination in favor of the larger mines shows favoritism. All mines, large and small, should be treated with the same severity and made to load clean coal if we would increase production and win the war. At our mine, we have been able to increase the output 20,000 tons, during the first six months of the present year, over the same period of last year. We have accomplished this with only 80 men. Let every mine, large and small, do its best to show the same increase, and we need not fear the results of the war.

Chambersville, Penn. JOHN BUGGY.

INQUIRIES OF GENERAL INTEREST

Accounting of Materials

Some time since, in connection with the discussion of the unwarranted waste of material in coal mining, there appeared an excellent letter in which the writer described a good system of accounting of all material ordered and sent into the mine from the supply house. I do not remember the name of the writer, but would like to ask that this subject be again presented for discussion by the readers of *Coal Age*, in the hope that there may develop a simple and accurate system of keeping account of the supplies on hand in the warehouse, as well as showing the kind and amount of material used each month in the mine. The record should also show who ordered the material, the date and where it was to be used. The blank form should be arranged in such a manner that credit can be given for all material returned as not used.

We are desirous of starting some such system at our mine, believing that it will greatly increase the economy of operation by causing the mine bosses to look after and keep track of what material is sent into the mine. Practical mine foremen should be able to offer some good suggestions along this line. What we greatly desire is to ascertain the most practical form of printed blanks that can be prepared for this purpose.

Carpenter Creek, Mont. OFFICE MANAGER.

We are glad our correspondent has referred to this matter of accounting of mine supplies, which is one of the most important features in operating economy. The letter to which he has referred was written by William Jardine, Universal, Ind., and appeared in *Coal Age*, Vol. 9, p. 265.

We quite agree with the suggestion that mine superintendents and foremen will be able to submit many valuable ideas in regard to keeping track of mine supplies, and shall be glad to receive and publish blank forms used both in the ordering and accounting of material, and learn of the system employed by the storehouse keeper and the mine foreman, in their accounting of material on hand and in use. The comparison of these systems will undoubtedly prove of inestimable value to those interested in coal-mining economy.

Calculating Velocities of Air

A question that has puzzled quite a few of us appeared, some time ago, in the *Science and Art of Mining*. The question reads as follows:

A roadway 7 x 6 ft. is ventilated part of the distance with a 20-in. trough and the remainder of the way by a brattice placed 3 ft. from one side of the entry. The velocity of the air in the trough is 416 ft. per min.; what are the velocities in the narrow and wide sides of the brattice, respectively?

In the *Science and Art of Mining*, the answer to this question was given as 50.4 ft. per min., for the velocity on the narrow side, and 21.6 ft. per min., on the wide side of the brattice. According to the rules given in the Scranton textbooks, the velocity of an air current varies as the square root of the sectional area of the airway; or, indicating the velocities and areas, respectively, by v_1, v_2, a_1, a_2, the formula given is:

$$v_1 : v_2 :: \sqrt{a_1} : \sqrt{a_2}$$

Applying this rule, however, does not give the answer quoted above. Kindly explain. STUDENT.

Edmonton, Alta., Canada.

In naming an airway, by giving its dimensions, it is customary to give the height of the airway first, and its width second. As a 6-ft. airway would be very narrow, however, we assume that this airway is 6 x 7 ft., or 6 ft. high and 7 ft. wide. The sectional area of the 20-in. trough or tube is $0.7854 \times 20^2 = 314.16$ sq.in., or 2.181 sq.ft., and the velocity of the air being 416 ft. per min., the quantity of air passing is $416 \times 2.181 = 907.2$ cu.ft. per minute.

The narrow side of the brattice being 6 x 3 ft., its sectional area is 18 sq.ft. The velocity of the air in this space is, therefore, $907.2 \div 18 = 50.4$ ft. per min. Also, the wide side of the brattice being 6 x 4 ft. has a sectional area of 24 sq.ft. The velocity of the air in this space is, therefore, $907.2 \div 24 = 37.8$ ft. per minute.

Regarding the rule given for the variation of velocity and sectional area, it should be stated that this rule applies only to the circulation of air in airways having equal rubbing surface and under the same pressure, which appears from the formula

$$p = \frac{ksv^2}{a}$$

In the present case, the *quantity* of air in circulation is constant and the velocity varies inversely as the sectional area, which appears from the formula

$$q = av$$

In determining the relation of the different factors of a circulation of air, it is necessary to study carefully the conditions presented by the formula, after eliminating all the factors that are constant. For example, the two formulas just given show clearly the following:

1. The rubbing surface and unit pressure (or water gage) in two airways being equal, the velocity will vary as the square root of the sectional area:

$$v \text{ varies as } \sqrt{a}$$

2. The sectional area and unit pressure being equal, the velocity will vary *inversely* as the rubbing surface:

$$v \text{ varies as } 1 \div s$$

3. For the same sectional area, the velocity varies as the quantity of air passing:

$$v \text{ varies as } q$$

4. For the same quantity of air in circulation the velocity varies *inversely* as the sectional area:

$$v \text{ varies as } 1/a$$

EXAMINATION QUESTIONS

Hoisting Engineers' Examination, Pittsburg, Kan., May 15, 1918

Ques.—What are the duties of a hoisting engineer?

Ans.—A hoisting engineer should be on hand 15 or 20 min. before the time for his taking charge of the engine, observe carefully its condition and working and oil and adjust any accessible parts that may need attention. He should not leave his post, after assuming charge, until he is relieved by another engineer.

Before starting to hoist, the engineer should examine all brakes, rope fastenings, oil cups, valves and bearings. It is his duty to acquaint himself thoroughly with every part of the engine and know and answer promptly the signals given him from the mine. He must never move the cage except in response to a clearly understood signal, or after giving due notice of his intention to do so, by the proper signal.

When hoisting men he must use special care to observe the position of the cage in the shaft and not exceed a safe limit of hoisting. The engineer must not allow anyone to loiter in the engine room or himself converse with persons while operating his engine. He must never attempt to take charge of an engine if sick or otherwise incapacitated for duty.

Ques.—Explain the difference between a geared and a direct-connected hoisting engine, and state which you would prefer for Kansas mines and why.

Ans.—A geared engine is one in which the winding drum is operated by the revolution of a shaft carrying a spur or pinion the teeth of which mesh into a gearwheel on the drum shaft. In a direct-connected engine, the winding drum is operated directly by the engine, without the intervention of a pinion and gearwheel.

As the coal mines of Kansas are generally shallow, not exceeding 80 or 100 yd. in depth, geared hoisting engines are to be preferred, for the reason that this type of engine permits of a greater number of revolutions of the engine, for the same depth of hoist, and, therefore, gives the engineer better control of his engine.

Ques.—What horsepower must be developed to raise a weight of 400 tons 150 ft. in an hour?

Ans.—The theoretical power, which ignores the friction of the hoist, is, in this case $(400 \times 2000 \times 150) \div (60 \times 33{,}000) = 60.6$ hp., assuming the short ton of 2000 lb.

Ques.—How do you determine the horsepower of a tubular boiler?

Ans.—The heating surface of this boiler, which is the entire surface exposed to the flame and gases of the fire and includes the tubes, boiler plates and boiler heads so exposed, must first be calculated. For return tubular boilers the ratio of heating surface to horsepower varies from 14 to 18. Therefore, to obtain the horsepower of such a boiler, divide the heating surface, in square feet, by a constant, which may vary between these limits.

Ques.—What are the advantages and disadvantages of using the water from the exhaust pipes of a hoisting engine, in a boiler?

Ans.—The advantage of using the water condensed from the exhaust steam of an engine is the saving thereby effected of the heat in the exhaust steam, which would otherwise be lost but which, in the condensation, passes into the feedwater and assists in raising its temperature.

One disadvantage in the use of the water from exhaust steam and feeding it into the boilers without sufficient treatment, is due to the oil contained in the exhaust steam. This oil is taken up by the steam in the cylinder of the engine and if permitted to remain in the feedwater and enter the boiler may result in coating the boiler plates and tubes with a film of oil, which would prevent the contact of the water with the metal and cause the overheating of these surfaces and the bagging of the plates or the formation of blisters.

Another disadvantage is experienced when the oil saponifies under the action of the alkali or alkaline earth contained in the feedwater. This is more apt to happen when an impure mineral oil is used in the cylinder of the engine, as the presence of vegetable or animal matter is necessary to cause the action.

In order to derive the benefit arising from utilizing the heat of the exhaust steam to raise the temperature of feedwater, the latter should be passed through an oil filter, consisting of a layer of charcoal or coke over a layer of hay, which will absorb the most of the oil contained in the feedwater, provided the material of the filter is renewed from time to time, as required.

Ques.—What is the number of revolutions per minute, of an engine having a stroke of 3 ft. 6 in. when the piston speed is 900 ft. per min.?

Ans.—Each revolution of the engine corresponds to a double stroke or a piston travel, in this case, of 7 ft. The speed of the engine is, therefore, $900 \div 7 = 128\frac{4}{7}$ r.p.m.

Ques.—What, in your opinion, is the best system of hoisting signals in use in the coal mines of this state?

Ans.—One bell or whistle signifies to stop if the cage is in motion; when the cage is at rest the same signal signifies to hoist the cage if the signal is given from the shaft bottom or lower the cage if given from the surface or upper landing. Two rings or whistles signify to lower the cage. Three rings or whistles signify men are ready to get on cage and are waiting for the engineer to signal them by one ring or whistle that he is ready, after which one ring to hoist or lower, as the case may be, requires the engineer to use extra caution if men are on the cage. Four rings or whistles should indicate that the cage is to be hoisted or lowered slowly and with caution, owing to the uncertainty of its load. *Coal Age, Vol.* 10, *p.* 85.

COAL AND COKE NEWS

Uniontown, Penn.

Fifty thousand tons of coal were lost last week by a coal car shortage which has reached an acute stage in the Connellsville coke regions, according to a statement issued at the office of the regional fuel administration. There was an added shortage of 1274 cars over the week preceding, and that fact coupled with the shifting to coal shipment of a number of Frick coke plants due to the demands for coal by the Clairton byproduct works, created a situation which held the attention of both the fuel and railroad administration representatives in this region. The region's coke output aggregated 316,381 tons, while the coal figures showed a production of 199,957 tons.

W. L. Byers, manager of production for the Connellsville region fuel administration, has issued an appeal to miners and coke drawers to make claim for deferred classification to the draft authorities. He told the men that in their work they were rendering as valiant a service to the country as if they were in uniform, and that the region could ill afford to lose many of its coke workers. Employers were urged to coöperate with the men in the preparation of the necessary affidavits. The new age limits of the draft will take in the great majority of the workers in the coke region, and Mr. Byers' appeal was issued to assure the men that no taint was attached to the application for deferred classification.

Charleston, W. Va.

Coal mine operators from all parts of the New River and Winding Gulf section gathered here last Monday to devise ways and means of speeding up the production of coal, that being the object of the meeting, over which C. C. Beury, chairman of the New River Association, presided.

As the first speaker, T. A. Scott, of the New River Company, outlined what the production committee of the National Coal Association was endeavoring to do to aid the United States Fuel Administration in its efforts to increase the output of coal. Mr. Scott favored immediate action on any plan which would result in an increased production.

E. E. White, president of the E. E. White Coal Co. and chairman of the Winding Gulf Association, as well as the newly appointed production manager for the Winding Gulf and New River districts, briefly outlined some of the plans for increasing production he had in mind, but emphasized the necessity of coöperation of not only operators and miners, but the public in general in getting out coal.

J. D. Parrish, superintendent of the Charleston & Ohio R. R., assured the operators present that he appreciated the cooperation of all of them and would be glad to have any suggestions as to how the car supply might be bettered. He said the railroads hoped soon to be able to furnish a car supply sufficient to meet all requirements.

Sanction was given by the association to a plan to establish a production office in Charleston with T. L. Lewis, secretary of the New River Association, in charge. Mr. White, of course, being the executive of the committee. The office has already been organized and plans set on foot to wage a campaign for greater production, operators present pledging their support.

Pocahontas and Tug River Districts

The Pocahontas and Tug River districts are recoving somewhat from the slump which followed closely on the heels of the banner week of July 29. While, of course, those districts have felt to a slight extent the car shortage, yet it has never been felt to the same extent as the inability to get the miners to put in more time, a problem which has been worked out partly although the mines in the southern part of the state are far from having a quota of miners large enough to meet the capacity of all mines. More negro labor has been used in the mines in the southern tier of counties than anywhere else, and many colored men have been drafted. It is hoped, however, by refraining from frequent celebrations to gain more time to be used in mining coal.

Kanawha District

Lack of cars is still playing hob with the production of coal in the Kanawha district. While assurance has been given by the Charleston & Ohio Ry. and the Fuel Administration at Washington, little relief has been afforded so far and consequently it is certain that the mines in this region will fall far below last month in the total output. The total production in the Kanawha district last week was 170,431 tons, a slight increase over the previous week, but below the same period of last month. Just how serious the car shortage is may be gathered from the fact that 2560 hours were lost from this cause. Although a less number of hours were worked the cutters had enough coal cut to increase the total tonnage. Hours lost from labor shortage amounted to a total of only 183.

New River District

The New River District, generally speaking, has been one of the few in the State of West Virginia which has not suffered from a poor car supply, but even that district was retarded slightly this week and last week on one or two days by an absence of cars. While not experiencing any such trouble now, the mines in the New River field have been hampered in getting out coal by poor power supply. For a time the operators never knew at what moment their power would be cut off. Now, however, there seems to have been an improvement, but in order to insure a reliable supply in the future there has been some talk of employing an electrical expert to work with the operators and a representative of the power company, in order to determine just where any lack of efficiency might exist.

Fairmont District

The continuation of the poor supply of cars in the Fairmont district over a period beginning about the 1st of the month has kept down the output, and conditions may almost be compared to those prevailing in the district last winter, the run of cars not averaging much over 800 during the first three weeks of the month. Each week the supply starts off well enough, but the experience of Fairmont district mines is that before the week is over the number of cars furnished is far below requirements.

Late placing of cars is also retarding production. For instance, while there were 1732 cars in the Fairmont district Monday of this week, many of them were placed so late that no miners were on hand to load them. Conditions in general did not point to any betterment in the car supply in the field during the week. Requisition had to be made to all mines for railroad fuel this week to meet the shortage of last week, when not even enough cars were furnished to load railroad fuel. During the first part of the week the shipment of coal eastward was limited to 900 cars a day. That gas coal should not be used for railroad fuel in view of the necessity for byproduct coal, is the belief among operators of the Fairmont district.

Winding Gulf District

If there has been any failure on the part of Winding Gulf District mines it has not been due to any lack of effort on the part of those in the industry, but rather to transportation difficulties. With six engines of the largest type in commission, the Virginian Ry. gives promise of being able to handle more cars in and out of the region. It is probable that even four more engines will be added to the motive power equipment in the Winding Gulf region. More coal is being mined in the Winding Gulf region as a result of get-together efforts of operators and men. That a sincere, serious effort is being made by the Chicago & Ohio Ry. to supply more cars is the statement of Superintendent Parrish, of Huntington, who has expressed the belief that much would be accomplished if operators and miners would seek a closer relationship with trainmen.

Dallas, Tex.

Plans are being worked out with the approval of the officials of the Federal Fuel Administration in Texas by which it is hoped to secure coal from the mines in Mexico just across the Rio Grande sufficient in quantity to care for all local needs in Texas. Manuel F. Palacio, of Saltillo, Mexico, has gone to Detroit for a conference with Henry Ford relative to securing motor trucks in sufficient number to transport needed coal from the Mexican mines. Mr. Palacio carries with him letters from Governor Mireles of Coahuila, Mexico, and also from Governor Hobby of Texas, setting forth the situation and giving indorsement to the plan.

Mr. Palacio proposes to secure motor trucks and transport coal from the mines in Mexico located only a few miles south of the Rio Grande opposite Laredo and Eagle Pass. The coal of these mines, it is claimed, is equal in quality to the best Pennsylvania anthracite, and General Carranza and Governor Mireles have given permission for the mine operators to transport the coal to the border for the use of the people of the United States. These mines are just being developed and could be made to increase their output greatly if a market for the coal is found in the United States and means for transporting the coal to the border is provided.

Present prospects in Texas are that the people of the state will have to depend on wood and lignite for heating purposes unless a way is provided for getting coal from Mexico. The coal in Mexico can be produced at a low cost and the expense of transporting it to the border if motor trucks can be had will not be great. From the border the coal can be hauled to all parts of Texas and other states by rail.

PENNSYLVANIA

Bituminous

Uniontown—Deed for the sale of an undivided one-half interest of 150 acres of Springhill township Fayette County, coal to the Hecla Coal and Coke Co., was placed on record here recently. The sale was made by Charles H. Seaton and Lizzie S. Bowman for $60,255, or at an average of more than $800 per acre. The other half interest is involved in the J. V. Thompson estate. The Crystal mine of the Hecla company adjoins the new field.

Uniontown—Damage to the extent of $50,000 and forced suspension of the mine was the toll of a fire at the Gates tipple of the H. C. Frick Coke Co. The fire is supposed to have been started by a bolt of lightning during an electrical storm. The tipple itself is mostly of steel construction and was but little damaged but the shaft timbers were burned. During the same storm the mine of the Plumer Coke Co. located nearby, was flooded. The Gates mine fronts the Monongahela River and is now shipping its output by water to the Clairton byproducts plant.

Pittsburgh—The Crucible Coal Co. is negotiating with the Cornell Coal Co., of Creighton, for the purchase of the holdings of the latter company.

Blairsville—The Brown Coal Co., of this city, has begun work on the reopening of the old Hart mine near Clarksburg. The company has made arrangements to dump its coal off the Lowther Coal Co. tipple at Clarksburg.

Evans City—The Big Creek Coal Mining Co. has begun improving its mining town at Wahlville, near here. All the houses are being wired for electricity and the current will be furnished by the company. Water is also being piped into the houses and drilled wells will replace the old reservoir. The production of the mine was recently increased by the installation of electric power for mining machines and haulage systems.

Anthracite

Hazleton—On Aug. 26 the Wyoming Valley Water Supply Co. received permission from the Commonwealth to construct a new reservoir at Tomhicken. This will permit

the abandonment of the old dams, which are over rich anthracite coal seams that the Lehigh Valley Coal Co. wishes to mine.

WEST VIRGINIA

Lannat—The No. 4 Superior Coal Co. is building a new plant here and will install electrical equipment. The company was organized by W. J. Luttrell, J. W. Reedy, C. R. Luttrell and others.

Clarksburg—Extensive coal property, in which Pittsburgh business men are interested in part, located on Shinn Run, Harrison County, will be developed by the Shinn Run Coal Co., incorporated by F. P. Patterson, H. T. Klingensmith, E. C. Peeler and N. K. Taylor, all of Pittsburgh, and by Guy A. Hardesty, of Shinnston. The company has an authorized capital stock of $50,000.

Clarksburg—The leasehold on the Titchnell coal properties at Meadowbrook, near here, held by the Madigan-Johnson Coal Co., has been sold to new interests. It is understood that the new owners are planning to increase operations at the plant.

Lynch—The United States Coal and Coke Co. is planning for extensive improvements and additions at its coal mining properties near here, to provide for increased operations. At the present time the works have a capacity of approximately 10,000 tons daily.

Charleston—The Columbia Coal Co., Union Building, is planning for the installation of mining machinery, including electric equipment for operation, at its properties, for the development of about 300 acres of coal lands.

Huntington—That there exists an urgent need for at least 7500 more men to man the coal mines of West Virginia is the opinion expressed by Agent John G. Wilson, of the Huntington branch of the United States Employment Service. It will be necessary to replenish the ranks of the miners depleted in various ways in order to bring the mines of the state up to their fullest capacity. With the addition of 7500 men, the employment agent estimates that 75 mines could be operated, each man producing anywhere from 16 to 20 tons during an eight-hour day.

KENTUCKY

Sturgis.—The machine shop and stables, including livestock, of the West Kentucky Coal Co. Mine No. 2, at this place, were recently destroyed by fire. The damage was estimated at about $10,000.

Hazard—The Midland Mining Co., which recently filed notice of an increase in its capital from $100,000 to $150,000, to provide for expansion is now developing approximately 1800 acres of coal properties in the Hazard district. H. E. Bullock is president.

ILLINOIS

Danville—A new strip mine will be opened by White, Barger & Co., four miles southeast of this city. The new mine will be in the Grape Creek district, the opening of which mining field placed Danville in a leading place in the mining world. The seam runs 7 ft. 2 in. to 8 ft. 7 in., with an overburden of from 12 to 18 ft. of earth. C. J. White, a pioneer worker in the strip mining field, will be interested in the new company. He installed the Beech Flats mine at Rush Run, Ohio, said to the largest strip mine in the United States. This mine is owned by Danville capitalists. W. G. Hartshorn will be the president of the new company. He is a worker of a number of years' standing in the mining field, having opened ten mines in Illinois, three in Ohio, two in Alabama and one in Indiana. A. W. White will be the active manager of the new project and John W. Barger will also be active. The mine will cater to Danville trade, wagon business to have first attention.

Harrisburg—Unsatisfactory power supply in the Harrisburg and Carterville districts has led to a suggestion, which the operators are considering that Keokuk dam power be used. At present power is being obtained from an operating company, which generates its own power and supplies other operators with the surplus.

Carlinville—It is reported that the Union Pacific R.R. is planning to open up extensive coal fields in this section of Illinois. A field of 60,000 acres east and southeast of town is said to have been bought up for the company, which is expected to sink three big mines, one near Moore's branch, another southeast of town and a third to the south. The field is held in the name of the Illinois Union Coal Company.

Springfield—Efforts of Sangamon county florists and proprietors of greenhouses have resulted in a modification of the order issued some months ago by the National administration limiting them to 50 per cent. of coal during the year 1918. The modification, which applies to the entire State of Illinois, permits them to have a 100 per cent. supply where in the opinion of the state fuel administration it does not interfere with the coal supply of industries working on war orders, provided that they use one-half of their coal in the form of screenings.

Springfield—The tipple of Citizens' Mine A collapsed a few days ago and threw nearly 250 men out of employment and curtails production in Sangamon County 1500 tons a day until it can be repaired. No one was injured. While repairs are being made limited production is maintained by hoisting through Mine B, the galleries of which connect with those of Mine A.

Gillespie—The order forbidding shipment of coal to coal-producing communities is causing trouble here. The Superior Coal Co. is a large producer here but does not sell for home consumption. A local mine is being sunk, but it will not be ready for several months. C. T. Woodward, county fuel adminstrator, is looking into the situation. The same state of things exists at Greenfield.

Decatur—Decatur mines are working 100 per cent. efficiently. They are from 30 to 60 days behind in their coal orders and are now hoisting 1000 tons of coal daily, which is their capacity. Local manufacturers are storing large volumes of coal and there is every indication that householders will do the same. No coal is going out of Decatur and Macon Counties. The fuel situation in general for the coming year is regarded as favorable, and this means much, as Decatur is a large industrial city. The Wabash Railway Co. alone has stored 30,000 tons of coal in its Decatur yards.

Carlinville—A new coal shaft is being sunk by local capital, the idea being that the new mine will be able to supply coal for local consumption by the opening of the winter season. The new mine is located near the Carlinville Clay Co.'s plant, south of town. A. H. Bell is the president and C. H. McIntosh, secretary.

Panama—The loss of the Panama local of the United Mine Workers through the alleged dishonesty or dereliction of its officials will not be as great as was at first thought, according to a report of an investigating committee composed of A. E. McReaken, James Hicks and Frank Hartman. The shortage was at first estimated at $15,000. A good deal of the money has been repaid and it is understood the loss will not be more than $3000. A warrant has been issued against a former official who is missing.

Edwardsville—Coal operators in this section are experiencing considerable difficulty on account of the scarcity of water. Continuous operation of the mines through the summer, coupled with the drought, which has been only partially broken, has depleted the lakes and ponds upon which most of the mines depend. Most of the operators have had to resort to tank cars. About 125,000 gallons are being "tanked" out of Alton each day.

ARKANSAS

Fort Smith—W. J. Pendergrass, of this city, and associates have organized the Majestic Coal Co. for the purpose of opening a 600-ton mine, two miles from Midland. Application to open the plant has been approved by the Fort Smith fuel administration. The company owns 250 acres of coal land and has a lease on 300 more acres. The coal is 3 ft. thick and the property is located a half mile from the Midland Valley railway tracks. It is the intention of the corporation to begin sinking a slope as soon as the application is approved by the National Fuel Administration.

Foreign News

London, England—Dissatisfied with a wage award which they considered unfair, a large number of miners in the Yorkshire coal fields went out on strike on Aug. 22. The strike lasted for only one day, as the men returned to work after the employers granted all demands.

Edmonton, Alta.—Mines in this neighborhood are largely idle for want of orders. Twin City Coal Co.'s mine closed down for a week and work at other mines is reported slack. In spite of warnings issued, the majority of people are putting off buying in the hope of prices going down by reason of more men and teams being available during the winter. The Dominion Government is blamed for lack of definiteness in handling the coal situation as in all that has been done to encourage the East to buy Western coal there has been some sort of qualification which has discounted the recommendations.

Personals

Richard Nesson, of Springfield, Ill., has been appointed mine inspector for the Litchfield district, succeeding Thomas A. Lewis, who resigned to take up another line of work.

W. B. Gathright, for the past 14 years connected with the Louisville office of the St. Bernard Mining Co., of Earlington, Ky., has been named assistant manager and sales agent succeeding the late Julius Bierach, who died early in the month.

Vance McCarty, for the past 12 years manager of the Pittsburgh branch of Edward R. Ladew Co., Inc., manufacturer of leather belting, has been appointed general sales manager of the company, with headquarters in the New York office, 54 Franklin Street.

Howard Marvin, formerly manager of Boyts Porter and Company, of Connellsville, Penn., manufacturer of the Yough mine pumps, has been made general manager of the International Clay Machine Co., of Dayton, Ohio, manufacturer of mining machinery.

Obituary

Albert E. Waggle, of Monroeville, Penn., mine superintendent at the local mine of R. H. Cunningham, was killed on Aug. 14 by the premature explosion of a blast. Mr. Waggle was 55 years of age.

Charles E. Gartside, a pioneer Illinois coal operator, died last Wednesday at St. Luke's Hospital. He had been sick four months. He was 68 years of age. Formerly he was for 40 years president of the Gartside Coal Co., succeeding his father, Joseph Gartside, founder of the company. He retired several years ago.

Recent Coal and Coke Patents

Mechanical Stoker. A. G. Elvin, A. B. Fahnestock and F. H. Clark, New York, N. Y., 1,267,644. May 28, 1918. Filed Sept. 20, 1917. Serial No. 192,260.

Coal Washing Apparatus. L. L. Llewellyn assignor to Pittsburgh Coal Washer Co., Pittsburgh, Penn., 1,267,565. May 28, 1918. Filed Jan. 5, 1918. Serial No. 210,415.

Supporting and Adjusting Mechanism for Mining Machines. N. D. Levin, assignor to Jeffrey Manufacturing Co., Columbus, Ohio, 1,267,675. May 28, 1918. Filed Sept. 30, 1911. Serial No. 652,099.

Regenerative Coke Oven. E. Coppeé, Brussels, Belgium, 1,267,380. May 28, 1918. Filed July 28, 1914. Serial No. 853,603.

Furnace Regulator. C. H. Stalker, Ann Arbor, Mich., 1,267,601. May 28, 1918. Filed Oct. 16, 1916. Serial No. 125,845.

Manufacture of Fuel Blocks or Briquets. E. R. Sutcliffe, assignor to Pure Coal Briquettes, Ltd. Cardiff, Wales, 1,267,711. May 28, 1918. Filed Mar. 27, 1915. Serial No. 17,504.

Gas Producer. J. W. Hornsey, assignor to General Reduction Gas and Byproducts Co., a corporation of Delaware, 1,267,410. May 28, 1918. Filed July 3, 1914. Serial No. 848,704.

Mine Elevators, Car Lock for. S. Galli Breegy Hill, Kan., 1,268,001. May 28, 1918. Filed Jan. 4, 1918. Serial No. 210,305.

Smoke Consuming Furnace. O. D. Orvis, New York, N. Y., 1,267,446. May 28, 1918 Filed Oct. 23, 1916. Serial No. 127,115.

Mining Machine. R. E. Dunlop, assignor to Jeffrey Manufacturing Co., Columbus, Ohio, 1,267,992. May 28, 1918. Filed July 28, 1914. Serial No. 853,644.

Stoking Mechanism. H. L. Moore, Pittsburgh, Penn., 1,267,439. May 28, 1918. Filed June 19, 1916. Serial No. 104,628.

Coal Washing Trough. G. E. Alleman, Shoemakersville, Penn., 1,268,531. June 4, 1918. Filed Aug. 25, 1917. Serial No. 188,098.

Dumping Car. A. Lichtenstein, Brooklyn, N. Y., 1,268,588. June 4, 1918. Filed Mar. 21, 1917. Serial No. 156,354.

Method of Mining Coal. A. H. Kuhn, Pittsburgh, Penn., 1,268,584. June 4, 1918. Filed Aug. 14, 1914. Serial No. 856,850.

New Incorporations

Adams, N. Y.—The Adams Coal Co. has filed notice of an increase in its capital from $35,000 to $50,000, to provide for expansion.

Whitesburg, Ky.— The Kentucky-Harlan Coal Co. Capital, $100,000. To develop coal properties in Harlan County. George F. Ryan is the principal incorporator.

Wellsburg, W. Va.—The Ohio Valley Fuel Co. Capital, $100,000. To operate coal mines in the Ohio Valley section. J. K. Wells is the principal incorporator.

Pittsburgh, Penn.—The Victory Coal Mining Co. Capital, $50,000. To operate coal properties in the Pittsburgh field. J. Fred Morlock, of Buffalo, N. Y., is treasurer.

Wheeling, W. Va.—The Ohio Valley Fuel Co. Capital, $10,000. To develop coal lands in Brooke County. Incorporators: J. K., M. L. and S. G. Wells.

Cassville, W. Va.—The Cass Hill Coal Co. Capital, $50,000. To operate coal properties in the vicinity of Cassville. Incorporators: R. L. Stallings, C. C. Hetzel and G. H. Hetzel.

Wilkinsburg, Penn.—The Wilkinsburg Domestic Coal Co. Capital, $50,000. To develop coal properties in the Wilkinsburg district. S. R. Hall, of Jeannette, is the principal incorporator.

Charleston, W. Va.—The Harmon Coal Co. Capital, $50,000. To mine for coal in the Charleston field. J. C. Gary, James E. Staton and A. F. Harmon are the principal incorporators.

Kittanning, Penn.—The Pittsburgh & Fennelton Coal Co. Capital, $50,000. To operate coal properties in the vicinity of Kittanning. C. H. Dyer, of Pittsburgh, is the principal incorporator.

Pittsburgh, Penn.—The Lebanon Block Coal Co. Capital, $25,000. To develop coal lands in the Pittsburgh field. William M. Swart, of Dormont, is the principal incorporator.

Jackson, Ky.—With a capital of $60,000, the Panhandle Coal Co. has been organized to develop mine property. W. O. Bender, E. O. Bailey and E. I. Hawkins are the principals.

New York, N. Y.—The Adelphi Coal Co., Inc., a Maryland corporation, has filed notice of authorization to operate in New York with a capital of $50,000. P. L. Vannorden, 1 Broadway, will act as local representative.

Chattanooga, Tenn.—Loomis & Hart Mining Co., capital $10,000, has been incorporated by Gaston Raoul and others, to operate coal mine on Raccoon mountain, to supply coal for the Odorless Refrigerator Co., of Chattanooga, with which Raoul is connected.

Hazard, Ky.—The Midland Mining Co., Lexington, has secured 1800 acres of land near Hazard and plans early development. The organization is capitalized at $150,000, having recently increased its stock from $100,000. D. L. Pritchard has been named construction engineer and H. E. Bullock president.

Henderson, Ky.—The Uniontown Coal Co., capital $100,000, has been incorporated by C. C. Porter, president, Dandridge Spottswood, vice-president and general manager, and J. H. Turner, secretary-treasurer. Henderson, Ky., will be headquarters of the company, while the officers are all Nashville men. The company has secured an operating mine at Uniontown, Ky.

Chattanooga, Tenn.—The Laurel Fork Lumber and Coal Co., capital $60,000, has been incorporated by Albert Crumley, H. M. Gordon, John Morrow and others. The Suck Creek Coal Co., also of Chattanooga, has increased its capital from $50,000 to $200,000. At Huntsville, Tenn., the Big Spring Coal Co. has been chartered with a capital of $12,000 by J. T. Prather and others.

Industrial News

War, W. Va.—The Bradshaw Coal Co. is building 60 houses for miners at its plant here, and also putting in a good deal of new electrical equipment.

Clarksburg, W. Va.—A 150 kw. electric plant is to be installed by the Valley Falls Fuel Co. The company expects to have the new power unit in operation within the next two months.

St. Louis, Mo.—St. Louis will begin at once the storing of coal on the levee at the foot of North Market St., adjacent to the new municipal dock, from which a track will be laid. A stock of about 15,000 tons will be placed there as a reserve.

Hawesville, Ky.—The Central Kentucky Block Coal Co., which was incorporated with a capital of $200,000 a short time ago, plans development of 2000 acres of land, for a daily capacity of 500 tons, and plans installation of equipment.

Lexington, Ky.—George F. Ryan and others are behind the Kentucky-Harlan Coal Co., according to report from Whitesburg, this concern figuring to develop coal mines and townsite near Harlan with capital of $100,000.

Lexington, Ky.—Jack Bryan and Louis Young, of Lexington, have purchased the Ivy Mill Coal Co. mines at Harlan, Ky., on Big Black Mountain, and plan extensive improvements and developments of the property.

Bluefield, W. Va.—Not only is new equipment being added to the Rolfe plant of the Pocahontas Fuel Company, but 37 new houses have been built. New equipment consists of 100 new mine cars. At the Cherokee plant of the company, 27 new miners' houses have been built.

Springfield, Ill.—The Springfield Board of Education has awarded to the Scott Coal Co. the contract for coal for the coming winter at these prices: Mine-run, $3; pea, $3.20; lump, $3.20; duff, $2.55; egg, $3.20, and screenings, $2.70. The Scott company was the only bidder.

Kimball, W. Va.—Many improvements are being made by the Houston Colliery Co., of which E. L. Stafford is superintendent, at the company's plant here. A new power house is being built and equipped with automatic stokers under the boilers; at the same time 25 miners' houses and a club house are being erected.

Whitesburg, Ky.—The Powell Coal Co., recently organized with a capital of $50,000, plans to develop lease secured from the Eureka Elkhorn Coal Co., handling two mine openings, and daily capacity of 500 tons. Material has been secured to erect tipple. Power plant and mining equipment will be installed.

Huntington, W. Va.—Announcement has been made by the Chesapeake & Ohio R. R. that figures for coal loading for the month of July show that all records for this work have been broken, a total of 3,145,105 tons having been loaded during this month. This amount is approximately 300,000 tons in excess of any previous month.

Chicago, Ill.—The Cement-Gun Construction Co. has recently completed the application of a waterproof gunite lining to the air shaft of the No. 11 mine of the Old Ben Corporation, Christopher, Ill., and is now engaged in doing the same work for the J. K. Dering Coal Co. at both the main shaft and air shaft of the new mine at Eldorado, Ill.

Pittsburgh, Penn.—In connection with extensive improvements at its Wheatland works, the Pennsylvania Railroad Co. has awarded a contract for the construction of a large new coaling station, including ash-handling department, the entire work being estimated to cost $150,000. The Crowell, Lundoff Little Co., Cleveland, Ohio, is the contractor.

Briceville, Tenn.—The Cross Mountain Coal Co., main office Knoxville, Tenn., which recently increased its capital from $400,000 to $500,000, plans development of 3000 acres of land, for a daily output of 600 tons. Willis P. Davis, formerly of Louisville, and connected with some large iron plants of Knoxville, is manager of the company.

St. Louis, Mo.—The Walter A. Zelnicker Supply Co. recently secured the services of Merle G. Peterson, who is now connected with the company's Chicago sales force at 428 First National Bank Building. Mr. Peterson was formerly associated with the Niles-Bement-Pond Co. and Pratt & Whitney Co. His father, Carl Peterson, is western representative of Baldwin Locomotive Works, with offices at Chicago, Illinois.

Crooksville, Ohio—An order has been issued by the federal director of railroads changing the contract of a small line 3.7 miles in length running between Sayre on the Zanesville & Western to San Toy. Formerly the line was controlled by the Baltimore & Ohio and a long route was covered to permit the coal mined on the line to be shipped to the market. Now the coal will go out over the Zanesville & Western.

East St. Louis, Ill.—The contract for supplying the city's fuel repirements from Aug. 1 to May 1 has been let to Frank Maule at $4.20 a ton, subject to any increase caused by a Federal order or an increase in freight rates. The contract calls for 2-in. screenings. The Cahokia Coal Co. and the John T. Maule Co., each bid $4.40 a ton. Last year the price was $3.10 and $3.25 a ton. The consumption is about 800 tons.

Williamson, W. Va.—Improvements costing $40,000 are being made to the plant of the Standard Thacker Coal Co. at Chattaroy under the direction of L. G. Bray, general manager. By such improvements it is hoped to increase the capacity of the plant 10,000 tons annually, giving a total production of 75,000 tons a year. Work was started on these improvements on July 1, and it is believed that they will be completed by Oct. 1.

Charleston, W. Va.—There was a total of 44 deaths in West Virginia during July as a result of accidents in the mines. Four of such deaths were outside the mines and forty within the mines. Twenty-five deaths were caused by falling roof and coal. Eight miners met their deaths on or under mine cars, motor cars killing four. Live wires caused the death of three. There were seven deaths each in Districts 13 and 14. Thirty Americans were killed, the rest being foreigners.

Toledo, Ohio—Considerable activity prevails at the docks of the lower lake ports, which is shown by the records of loadings at the Toledo docks of the Hocking Valley and Toledo & Ohio Central railroads. The Toledo & Ohio Central docks during the week ending Aug. 17 loaded 92,000 tons as compared with 78,000 tons the previous week, making a total of 1,120,000 tons for the season. The Hocking Valley docks during the same week loaded 197,837 tons as compared with 169,928 tons the previous week, making a total of 2,482,000 tons for the season.

Indianapolis, Ind.—Shipments of coal to 41 industrial plants in Indiana have been discontinued because these plants have been stocked with a sufficient supply of coal to meet needs for several weeks. The order was issued by R. L. Flood, of the quartermaster's corps, assigned to coöperate with the Indiana Fuel Administration in establishing priority shipments of coal to industries engaged in war work. The order was made following instruction which had been received by A. M. Ogle, director of state distribution of the Federal Fuel Administration, that plants with excessive supplies of coal should receive no more coal. It is said that some plants have enough coal on hand now to operate for a year.

Indianapolis, Ind.—A tentative plan has been drawn up regarding the distribution of coal among the 54 cities of Indiana which are entitled to receive anthracite. The plans were agreed upon by Alex R. Holliday, assistant fuel administrator of Indiana, and H. N. Pease, western representative of the anthracite department of the Federal Fuel Administration. Officials of the state administration state that it will be impossible to divert any of the anthracite coal from any of the 54 cities which are designated by the order.

Pineville, Ky.—The property of the Federal Coal Co., which owned and operated a number of coal mines on Straight Creek, was sold on Aug. 19 by Judge J. M. Gilbert, as Special Master under a decree of the United States District Court of eastern Kentucky, for $1,400,000. The stocks and bonds of the company are owned by Louisville and Chattanooga parties, who organized the Federal Coal Co., to take over the property of the Continental Coal Corporation, which filed a petition in bankruptcy. Disagreements arose between the Louisville and Chattanooga interests concerning the management of the property under the reorganization, and the property was again thrown into court. Several months ago a division of the property was made as between the Louisville and Chattanooga interests, the latter taking the property on the Left Fork of Straight Creek, the Louisville interests taking the properties on the Right Fork, which embraced the property of the old Straight Creek Coal and Coke Co., which was owned by Louisville capitalists and by them sold to the Continental Coal Corporation. The latest sale was made to C. M. Preston, of Chattanooga, and Thurston Ballard, of Louisville, representing the two interests. The property which goes to the Louisville interests is now being operated as the Liberty Coal and Coke Co., under the management of Judge M. H. Barker, of Louisville.

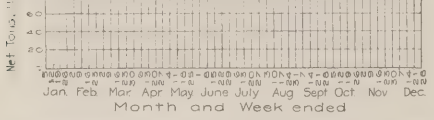
MARKET DEPARTMENT

Weekly Review

Coal Output Shows Further Decrease—Poor Car Supply and Layoffs Keep Down Tonnage—Reserve Stores of Coal To Be Limited—Northwest Shipments Show Improvement —Market Conditions Quiet—Nonessential Industries Have Poor Outlook for Fuel

PRODUCTION of bituminous coal continues to decrease in spite of all efforts made by operators and Fuel Administration officials to speed up production. The causes for the poor output still remain the chronic ones of insufficient cars and slacker labor. Many of the producing districts report that their operations have been forced to suspend for periods ranging from half a day to four days because they were given no cars to load. Not only does this poor transportation situation result in meager tonnages, but patriotic labor that is anxious to prove its good intentions toward the country at the present time is denied the opportunity to work steadily. Then, again, pay day at many mines is still followed by an increase in the percentage of absentees, men whose craving for a spree or a layoff is stronger than the pleas made by speakers throughout the mining regions that coal is needed to win the war.

During the week ended Aug. 17 inadequate car supply and labor shortage combined to keep the output of soft coal down to 11,910,000 net tons, which is far below the weekly figure of 14,270,000 net tons considered necessary to meet essential demands. It is a foregone conclusion that some drastic policy will have to be put into effect if war work is not to suffer, and an intimation of the manner in which the situation will be met is indicated by the announcement of the Fuel Administration that stocks of steam, byproduct and gas coals are not to be hoarded, regardless of whether the consumer with the reserve stores is in a preferred or nonpreferred industry. Mandatory limits have been set on the number of days' supply of fuel which may be stored by industries in different sections of the country, and the Fuel Administration will see to it that these limits are not exceeded.



Anthracite production during the week ended Aug. 17 totaled 1,924,800 net tons, which is not only a falling off of 127,133 net tons compared with the week of Aug. 10, but is 63,800 net tons under the quantity mined in the same week of last year. Inadequate labor forces are chiefly responsible for the loss in anthracite output. Since April, 1918, to date, however, the total production of hard coal amounts to 39,634,247 net tons, an increase of 723,969 net tons over the quantity mined in the like period of 1917.

The movement of coal to the Northwest shows signs of improvement, though the tonnage is still considerably behind pre-season estimate. Bituminous coal loaded on vessels at lake docks during the week ended Aug. 17 amounted to 1,109,611 net tons, an increase over the week preceding of 85,192 net tons. Supreme efforts will be required if the Northwest requirements are to be met before the close of the lake season.

Market conditions are quiet in both the steam and domestic grades. Dealers' stocks are generally quite low, but there is some coal in the yards of retailers and consumers are still placing orders. The heavy storage demand from domestic consumers has been satisfied to a large extent, and there seems to be little danger of a serious shortage in domestic fuel next winter. However, conservation measures are the order of the day, and there will doubtless be further curtailment of labor, transportation and fuel in activities that fail to come within the classification of strictly essential. It is probable that many such concerns will find it necessary to suspend operations next winter.

COAL PRODUCTION

The decrease in production which began after the record week of July 13 not only continued during the week of Aug. 17, but the output during that week also fell below 12,000,000 net tons for the first time since June 22. Preliminary estimates place production (including lignite and coal coked) during the current week at 11,910,000 net tons, a decrease compared with the week of Aug. 10 of 379,000 net tons, or approximately 3 per cent, but an increase over the

corresponding week of 1917 of 1,597,000 net tons, or 15.4 per cent. Production necessary during the balance of the summer weeks to make past deficit now amounts to 14,270,000 net tons, 247,500 net tons or approximately 21 per cent. in excess of the average weekly production during the coal year to date. The average production per working day is estimated at 1,985,000 net tons, a decrease compared with the average daily summer requirements of 92,000 net tons or 4.5 per cent. but 266,000 net tons or 15.4 per cent. in excess of the average daily production during the week of Aug. 17, 1917.

Anthracite Production.—Production of anthracite in the United States during the week of Aug. 17 is estimated at 1,924,800 net tons, a decrease compared with the week preceding of 127,133 net tons or 6.2 per cent., and a decrease compared with the current week of last year of 63,800 net tons or 3.2 per cent. The average daily production during the week of Aug. 17 is estimated at 320,800 net tons, 4.5 per cent. behind the average daily production during the coal year to date and 2.8 per cent. behind the average daily production during the same period of 1917. Total production for the coal year to date is estimated at 39,634,247 net tons, an increase over 1917 of 723,969 net tons or 1.9 per cent.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: July 27	Aug. 3	Aug. 10	Aug. 17
Bituminous shipments, 123 roads	228,231	220,940	215,996*	207,822†
Anthracite shipments, 9 roads...	40,942	39,632	39,280	36,857†

* Revised from las' report. † Subject to revision.

Shipments decreased during the week from all districts with the exception of western Pennsylvania, Tennessee and Kentucky, Alabama and the Rocky Mountain and Pacific Coast states. Material decreases occurred in central Pennsylvania, from which districts shipments declined 2500 car loads, or 6.7 per cent.; from southwest Virginia, where shipments declined 221 carloads or 8.1 per cent.; and from the districts including Illinois, Indiana and western Kentucky, where shipments declined approximately 1700 carloads or 3.4 per cent Compared with last year, however, all districts show improvement. For the coal year to date, all districts with the exception of Michigan also report increased shipments over the same period of 1917.

Lake Shipments.—Bituminous coal loaded on vessels at lake ports (including vessel fuel) during the week ended Aug. 17 is estimated at 1,109,611 net tons, an increase over the week preceding of 8.5 per cent. and over the weekly average during the month of July and August of 9.9 per cent.

For the week ended Aug. 17, shipments of bituminous coal to New England are estimated at 586,918 net tons, an increase over the week of Aug. 10 of 3.4 per cent. Rail receipts through the New England gateways estimated at 204,864 net tons decreased 13.8 per cent. compared with the week of Aug. 10, while tidewater shipments estimated at 382,054 net tons increased 15.8 per cent. During the current week shipments from all harbors exceeded the average weekly shipments during the coal year to date, while rail receipts fell 5.9 per cent. behind.

Shipments of bituminous coal from all tidewater harbors during the week of Aug. 17 not only exceeded the shipments during the week preceding, but also the weekly average during the coal year to date with the exception of Hampton Roads. Shipments from all harbors exceeded the weekly average for the coal year to date by 6.5 per cent., from New York and Philadelphia by 3.6 per cent., and from Baltimore by 35 per cent., while shipments from Hampton Roads fell behind 3.8 per cent.

Beehive Coke.—The production of beehive coke in the United States during the week of Aug. 17 is estimated at 581,000 net tons, an increase compared with the preceding week of approximately 1 per cent. The average production per working day is estimated at 97,000 net tons as against 96,000 net tons during the week of Aug. 10

The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week of Aug. 17 of 368,323 net tons, their plants being operated at 71.7 per cent. of their present capacity as against 70.3 per cent. during the week preceding. Loss of time attributed to car shortage amounted to 2.5 per cent. of present capacity as against 0.6 per cent. during the week of Aug. 10, but such losses were offset by slightly improved yard labor conditions and other causes not reported.

Byproduct Coke—Operating conditions in the byproduct industry during the week of Aug. 10 were not as good as the week preceding, a slight shortage of byproduct coal causing the plants to be operated at 9.0 per cent. of their present capacity as against 91.5 per cent. during the week of Aug. 3. Operators in Illinois, Indiana, Kentucky, Maryland and Massachusetts report decrease in production. Factors limiting production in Kentucky and Massachusetts were repairs to plants, in Indiana coal shortage, in Illinois both repairs to plants and coal shortage, and in Maryland other causes. Improved operating conditions were reported in Pennsylvania and Tennessee. The installation of a battery of 51 ovens by the Youngstown Sheet and Tube Co. during the current week was the cause of the increased capacity in that state.

BUSINESS OPINIONS

Marshall Field & Co.—Shipments of dry goods for the week were very much in excess of the same period of 1917. Road sales for immediate delivery were larger than for the same week a year ago. Very few lines are being offered for spring delivery. Slightly fewer customers were in the market compared with the current week a year ago. Collections continue good.

Dry Goods Economist—Prices of all kinds of dry goods continue to advance and in most lines scarcity becomes more marked, while it is evident that this condition will become intensified with the increased purchases of the Government for the equipment of a greater army. In no branch of the trade is the shortage of materials so great, however, as in woolens and worsteds, both women's dress goods and fabrics for men's wear. The price of raw cotton has gradually advanced and speculation in the staple is active.

American Wool and Cotton Reporter—The cotton market is a speculative one, more or less influenced by traders and what happens from day to day. The underlying strength is the dry weather in the Southwest. The outlook for a large crop does not seem so favorable at present, but one thing seems certain, and this is that all the crop will be picked at present prices. The mills are not buying a great deal at present. The woolen goods market is gaining in strength. Fewer persons expect that there will be any allotment of raw material, and on this basis operation for the Government must increase, while at the same time production for civilian distribution must decrease. It is unlikely that prices will be made for woolen fabrics. If new wool is not available, it may be possible that substitutes will be apportioned, but even under such conditions, it does not seem likely that the production of fabrics for civilian distribution will increase greatly.

Bradstreet's—As regards the leading industries, it is useless to advert to anything else than the requirements engendered by the war, which involves the production of increased quantities of steel for ships and munitions. But it is impossible to greatly hasten outputs with supplies of coal, coke and labor entirely insufficient. From every part of the country save Texas come complaints about paucity of labor. In the section just excepted an influx of farmers from the drought-stricken areas has benefited the labor market. Under the circumstances, women are being inducted into industrial pursuits on a steadily extending scale. With new selective draft laws in prospect, further sweeping changes will ensue, and therefore it is not difficult to visualize the near-future situation of the so-called non-essential industries, many of which, however, will be diverted to war work. Crop news, particularly as regards corn and cotton, points to deterioration, but wheat is turning out better than earlier indicated.

The Iron Age—Coal and coke supply still limit pig iron and steel output. The continuance of an adequate labor supply under the new call for fighting men is a serious problem, and even more grave is the situation caused by the set purpose of labor leaders to bring about union control of the steel industry. The situation as to coal and coke and transportation does not measure up to the enlarged requirements of the war. With an average of 360 blast furnaces operating last month, the pig iron output was 110,000 tons a day. With an average of 335 furnaces operating in April, May and June of last year (25 less than in July, this year) the pig iron output for those three months also averaged 110,000 tons a day. Thus 25 more furnaces are required now to keep output up to the rate of last year. The pig iron shortage complained of for months grows more acute; but the proposal from Washington that the few remaining cold furnaces be started up will come to little. Operators of some of the small furnaces now blowing, particularly in the South, threaten to put them out if the pig iron price is not advanced by October.

Atlantic Seaboard

BOSTON

Awkward situation arises through pressure to unload water-borne coal. New England not equipped to take on easily so much coal within so short a time. Demurrage accrues, but consumers take their medicine cheerfully. New ruling on the reserve supply permitted different requirements. All-rail movement shows increase even over July, due to volume of wagon coal. Under the recent decision at Washington it is probable that current shipments to a large number of plants will be shut off, and the coal thrown to needs that have not been so well served. Baltimore piers badly congested and inquiries are persistent as to why normal movement to New York piers is not resumed. Detention also threatens at Hampton Roads. Anthracite volume only slightly reduced all-rail. Reading barges load at New York piers.

Bituminous—The recent agreement in Washington that New England should continue to have the benefit of the 30,000,000 net tons annually of bituminous has resulted in volume shipments on an even larger scale than during July. Both all-rail and by water, coal lately has been thrown at New England as if within the short space of a few weeks we must take all or go without. Both at Baltimore and at Hampton Roads there has been a bunching of steamers to load for New England, a great effort being made to make up this territory's quota, but the number of ships has increased to such extent that it is physically impossible to find enough berths for them at this end to discharge. The Boston & Maine R. R., for instance, needs coal in volume to build up a proper reserve against the winter, but today this railroad is obliged to release coal to other consignees because there are not sufficient discharging facilities at Boston, Portsmouth or Portland, to unload the coal without most expensive delays. Commercial coal for distribution inland, in many cases, has to be unloaded at the same wharves where railroad fuel is handled, and due to the increasing ratio of all-rail receipts of engine coal the past five years the railroads now find themselves unable to take on all the water coal that is offered them.

The ability of a large number of consumers to receive coal at this time is being limited in the same way. At this writing there is a steamer in Boston Harbor that has been waiting six days without an open berth. Larger ships have been taken care of meanwhile because detention of the latter is so expensive, but it is a commentary on the way shipments to New England have been handled that ships are kept waiting when there is a world-wide shortage of tonnage; $2.50@$3 is now nothing unusual for a demurrage charge, and while consumers inland and on tide water occasionally make wry faces their disposition is to accept the situation and be thankful for the coal. It is said there will be 70 steamers this week for Mr. Storrow's advisory committee to allocate, and it will be some problem not only to find cargoes for them all, but to find consignees willing to obligate themselves for the demurrage charges that are certain to accrue to high figures. All this makes a most awkward situation. It is obvious that three months from now, in the latter part of November, this territory will again be in great need of coal, and by that time all the shipping agencies will be swamped with demands from other quarters.

Perhaps the most important announcement of the week is the recent decision at Washington through a committee of state administrators of which Mr. Storrow was chairman, definitely naming the number of days' supply to be permitted different classes of consumers. The understanding is that these limits are to be rigidly adhered to, and that only in special cases and then on recommendation by state fuel administrators to Washington is any deviation to be allowed.

Receipts of bituminous at the five New England gateways show an even larger tonnage than during July. For 22 days in August the average number of cars passing was 723, including railway fuel. Receipts by water have been the largest on record. The increase in bituminous all-rail is due to the volume of wagon-loaded bituminous now coming forward in box cars at the rate of 100 cars or so daily. This coal is rather difficult to distribute just at this time because partly of the 75c. extra price, but chiefly because labor is scarce and it is difficult to free the cars promptly. The car service officials are on the qui vive to find stations where there is any delay in unloading cars, and this volume of box-car coal has to be spread around as thinly as possible.

Congestion continues unabated at Baltimore. It is shown that the piers there are not able to handle with dispatch the volume of coal sent there and in several cases steamers already on demurrage have been shifted to Hampton Roads because the outlook for loading at Curtis Bay was so hopeless. Those distributors on Long Island Sound who are normally dependent to greater or less extent upon coal from Baltimore & Ohio and Western Maryland territory are again asking pertinent questions as to why, if congestion prevails at Baltimore, cannot this congestion be relieved by allowing a greater tonnage to move to the New York piers in the usual way. The Baltimore & Ohio piers at New York are today handling less than 50 per cent. of the coal they could handle, and there is a surplus rather than a shortage of bottoms for Long Island Sound traffic. Of course, the great anxiety has been to furnish cargoes for the increasing number of steamers, but if both Hampton Roads and Baltimore are to be blocked with ships then some other move will have to be made.

The Hampton Roads situation is today rather uneven, but with extra detention threatening. Shippers are fearful that any moment a large tonnage will be ordered to byproduct plants or to line trade or taken for Government use at the piers and are therefore proceeding very cautiously on their commitments to load bottoms.

Anthracite—Receipts of domestic sizes at the gateways average 440 cars daily for the period Aug. 1-22, only a slight reduction in the tonnage as reported for July. Steam sizes are sagging off and today with the volume of bituminous in hand consumers are disinclined to buy further.

Reading barges are now loading at Port Reading, N. J., instead of at Philadelphia. This is partly due to submarine threatening and partly due also to an effort to speed up movement. The Port Reading piers, of course, have not the facilities and more than likely the extra detention there will more than offset the difference in mileage for the tugs. The Railroad Administration is still given to experiments but one could wish a more favorable time to try them out.

NEW YORK

Receipts of anthracite show gain and situation is an improvement. Tidewater conditions are better and with demand easing up dealers believe real danger is past. Steam coals are in good demand. Bituminous conditions easier with demand for bunker coals remaining heavy. No delay in loading vessels. Commercial coals scarce.

Anthracite—Receipts show a steady gain and dealers are beginning to feel that with consumers exercising a little care the situation next winter will be a large improvement over last. With coal coming here in slightly increased quantities, there is a strong feeling that dealers will be able to clean up most of the urgent orders now on their books, particular attention to be paid to orders of one and two tons. With this object before them there have been conferences between the Fuel Administrators and retail dealers in some of the Boroughs of Greater New York, but no definite plan has been outlined pending definite assurance from the Fuel Administration as to what can be done toward increasing receipts.

The dumpings at the local docks for the week ending Aug. 23 were 7616 cars, an increase of 547 cars over the previous week. On Aug. 21, 1409 cars were dumped, which is thought to be a record for any one day.

The tidewater situation is gradually getting better. More coal is being handled and dealers are not so urgent for shipments. Boats are plentiful, but the rates are high. Chestnut coal is running easier than either of the other sizes. Egg and stove continue to be tight, with pea in bad shape. The steam coal situation remains practically unchanged. Buckwheat No. 1 is in good demand and there is plenty to meet all needs.

sary demands. Some shippers find it hard to dispose of their stocks of barley and culm, owing to the scarcity of bituminous, but there is no grumbling. In some sections of the Greater City stove coal is in greater demand than egg.

The situation in Brooklyn and Queens, where fears have been entertained of a serious shortage, is picking up. Efforts are under way whereby every consumer will have some coal in his cellar by the time it is necessary to start the furnaces. It may be that the plan will include the dumping of the coal on the sidewalk and that the buyer will have to put it away in the cellar bins, much time being saved thereby.

It is expected that the full winter schedule of prices for coal at Tidewater will become effective on Sept. 1, although no announcement has yet come from Washington. This will mean an advance of 30c. per ton to the present prices for the domestic coals.

Current quotations, per gross tons f.o.b., tidewater, at the lower ports, are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.35	7.10	Rice.... 4.65	5.10
Stove... 6.60	7.35	Barley.. 4.15	4.30
Chestnut 6.70	7.45	Boiler.. 4.60	
Pea..... 5.20	5.95		

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—Judging from the tonnage dumped at the local docks during the week ending Aug. 23, consumers supplied by this market are getting their share of the output. There were 7091 cars dumped as against 6413 cars the week previous, a gain of 322 cars.

With the adoption at Washington of the report framed by state fuel administrators showing the maximum limits of storage, public utilities and preferred industries in Southern New York and New Jersey will not be allowed to have more than 30 days' supply of steam coal on hand, while non-preferred industries must get along with 15 days' supply. Of byproduct and gas coals, byproduct and gas plants may have 45 days' supply ahead and preferred industries may carry 30 days' supply.

The demand for eastern coals is steadily increasing, particularly for Navy and transport service. Locally the bunker situation is in good shape. Vessels are quickly loaded and there is no delay reported from that quarter, although the demands remain heavy.

The commercial coal situation is in good shape, considering conditions. Demand is heavy and consequently stocks at the docks are low. Some shippers with coal to their credit in the pools are surprised when they put boats in for it, to learn that it has been absorbed and that there is no coal for them.

There are persistent rumors of contemplated changes in the status of jobbers. These proposed changes, which are said to include the almost elimination of jobbers who have began business since April 1 of last year, are now said to be under consideration by the Washington authorities. There has been no increase in coals available for spot buyers and regular customers are getting good supplies.

Current quotations, based on Government prices at the mines, net ton, f.o.b. tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack.....	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine.....	3.08	5.23
Prepared.....	3.36	5.51
Slack.....	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite demand grows as summer wanes. Car service causes trouble. Greatest shortage of coal in suburban districts. Drastic ruling on long hauls. Production increases, and local shipments to some extent. Relative demand of sizes unchanged. Broken coal allotted. Lightless night violators fined. Bituminous suffers from car shortage. Production slightly off.

Anthracite—As the end of the month approaches the shipping companies are again besieged for coal. The small dealers, not only in the city but from the surrounding country, are becoming most persistent. When the smaller buyers learned that they must depend on their 1916-17 quota, with no opportunity of increasing their business, they anticipated no difficulty in obtaining their meager allotments and did not at first give the matter much concern. Now, with fall almost upon them, they appear almost panic stricken; and some who claimed their tonnage for the basic coal year was too insignificant to worry the shippers about are now clamoring for every ton. In many instances they are hunting up their county fuel administrators and appealing to them for aid.

The city fuel administration has just handed down a drastic ruling on long deliveries. All dealers have been notified that after Sept. 15 they must discontinue making deliveries to customers at exceptionally long distances from their yards. It is left up to the dealers to decide just what is a long haul. The authorities say the dealers have had all summer to look after such customers and after the above date they must turn such orders over to dealers nearby the customer. This ruling in a way recalls the rumors that were strongly current last spring that the authorities intended to district the city and the chief complaint of the retailers against the ruling is that the administration left it until so late in the season.

We still incline to the belief that the city is receiving an increasing proportion of fuel, but the dealers are not willing to admit this. Yet this week the largest retail company used considerable newspaper space stating that the orders which they had taken so far, and which they had expected to be until Oct. 15 in filling, were more than half filled and they notified the public that they would use every effort to fill the others and had hopes that they would be able to do so.

We have found yards in some localities that are practically full of coal, while an adjoining dealer has no stock at all. These cases cause bitter complaints from the latter class of dealers. Upon inquiry we learned that such cases are not at all uncommon, being caused by a shipper, usually a small operator, who desires to fulfill his obligations for the coal year to a certain customer and then close the business relationship with him. This of course cannot be understood by the dealer whose credit is good but who has no coal.

The dealers are becoming impatient at the delay of the railroad companies in adjusting claims. Coal is sometimes transferred enroute and the original consignee stands charged with coal for weeks. When coal is lost in transit, and for which the railroad companies always stand responsible, the dealers hesitate to accept it for fear of not being reimbursed for an indefinite time. It is only their urgent need of coal that impels them to accept it.

Egg and stove in the outlying sections and stove in the city proper are by far the scarcest sizes. Pea coal continues to be eagerly unloaded, but there is considerable in stock in several yards. As the exemptions from Washington on buckwheat coal are coming through more promptly for necessary consumers, this size is not so free with some customers as it was for a few weeks. However, we do know of one large company who has had sufficient of this size to offer to a few favored retail customers and while a few of them turned it down, others eagerly grabbed it and stored it away.

This week the anthracite companies were all notified of their allotments of broken coal which they are expected to ship from now on to the gas companies throughout the eastern seaboard. One company alone in this city is to receive 125,000 tons. Broken is a size that always has to be made specially, and as a matter of fact the companies can get a better price for the coal by breaking it down into the smaller domestic sizes.

This week over 100 persistent violators of the lightless night rules were called before the fuel authorities and fined. They had been given a number of warnings, but continued the violations, with the result that they were given the option of contributing to the funds of the Red Cross or being prosecuted.

The steam coal trade shows no sign of change, all sizes being quickly cared for. There is also some indication of a slightly increasing demand for culm locally, but the heaviest demand continues to be from outside points.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken.....	$4.90	$6.25	Buckwheat..	$3.40	$4.45
Egg.....	4.50	5.85	Rice.....	2.90	3.80
Stove.....	4.75	6.10	Boiler.....	2.70	3.70
Nut.....	4.85	6.20	Barley.....	2.40	3.30
Pea.....	3.45	4.70	Culm.....	1.25	2.15

Bituminous—There is much dissatisfaction still manifest over the distribution of cars in all districts shipping to this territory. The chief complaint comes from central Pennsylvania and it is the old story of one mine being short, while others have more than they can fill in a single day. This condition is again showing its effect in the labor supply, as the men are inclined to shift to the workings where the car supply is best.

Heavy consumers in the city, those on strictly war work, continue to get the heaviest shipments, and this is especially true of power plants, who now have the biggest stocks of their career on hand. There continues to be some delay in shipments at tide points to strictly coastwise destinations, although the overseas trade is not affected at all.

BALTIMORE

Successful application of plan to cut down coal supplies of preferred class here to be applied nationally. Jobbers as purchasing agents, working with fuel administrator of state, found solution for shortage. Hard coal men have labor and supply troubles.

Bituminous—After laying a plan before the National Fuel Administration about three weeks ago for the relief of an acute fuel shortage in non-preferred business classes here, the Maryland administrator was given permission to put it into practice. Reports gathered from all lines of industry here had shown that some of the preferred class had coal supplies on hand for from 90 to 155 days ahead, and with steady supplies that not only assured them of coal for immediate use but also some for additional storage. Other industries were shown with but a few days' supply on hand.

It was shown that the lists forwarded by the administrator to the district representative for filling had not been met because of lack of authority to divert preferred coal. The administrator was given permission to put stop-orders through the district representative to mines that were to supply industries here with large stocks on hand, and to order shipments to other industries without coal. The old jobbers' group, now purchasing agents, were then used to distribute all excess coal diverted here through the same means to the Maryland administrator, and this worked so successfully that the past week not only saw few complaints of business houses short of coal for immediate needs, but the administration was able to get enough coal running direct from mines to prevent any further stop-shipment orders being executed.

That the national administration last Thursday admitted the justice of the plan by ordering definitely that Maryland public utilities be allowed but 30 days coal in advance, along with the preferred industries of a war-character here, and non-preferred industries of the state but 15 days supply ahead, is of considerable interest. For gas coal the byproduct and gas plants are allowed 45 days' supply; preferred industries 30 days, and non-preferred no storage of this fuel. Limits for storage for industrial plants throughout the country are to be enforced.

Anthracite—The labor shortage is becoming more and more acute in this city, and many of the coal yards are unable to have their deliveries keep pace even with the comparatively small amount of coal allotted them. Unless some increase in price is granted the dealers, in order that they can raise the wages of drivers and yard helpers to a point where they can be retained against prices offered for war-work, the trade feels that a serious situation will develop shortly. Confronted by the July fall-off in tonnage and the fact that the spurt for early August is not now being maintained, Robert F. Roberts, chairman of the city committee of the fuel administrative force here, went to Philadelphia the past week to confer with the Anthracite Committee about speeding movement to give Maryland the allotment originally promised before heavy winter weather comes. He was unable to get any promise of improvement, however, especially in view of a decrease in tonnage production announced for the week. "We are doing the best we can," is the answer now to the cry for more coal reaching all branches of the fuel administration and the dealers themselves.

Lake Markets

PITTSBURGH

Car supplies uncertain. Supply of labor being considered. Coal very scarce.

Car supplies in the Pittsburgh district have improved slightly, but it is too early to determine whether this marks a general trend or is merely incidental. No official information is available as to whether the

Railroad Administration feels able to comply with the request of the district, made Aug. 16 through R. W. Gardiner, manager of production for the district, for a larger car supply, predicted largely upon the fact that during the first half of August there was a decided decrease in the car supply, although the July supply had not been satisfactory and had not permitted sufficient Lake shipments to promise making up the full Lake quota by Oct. 15, the date by which it had been hoped the Lake movement could be completed.

On Aug. 21 a conference was held between John C. Frazee, Federal director of the Public Service Reserve, and other representatives of the Federal employment service, with more than a score of the leading coal operators of the district, relative to the amount of labor the coal district could employ, but no definite figures were approved, chiefly because the matter hinges so largely upon prospective car supplies. It appeared that if the men now on payrolls would work full time the present car supply could be fully utilized. For an increased supply more men are in all probability required.

There is more complaint by byproduct coke ovens that they are not receiving full supplies, and this indicates the scarcity of coal, since byproduct ovens are given a high degree of preference. The shortage at byproduct ovens, however, is not regarded as serious, the chief matter being that it is desirable for them to accumulate a surplus against the winter.

The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, brokers being allowed to charge 15c. brokerage in addition. The brokers find practically no coal at this time.

TORONTO

Dealers months behind in deliveries and refusing orders. Many consumers unprepared for cold weather. Civic authorities promise rigid enforcement of restrictions. Quotations nominal.

Conditions as regards coal supply have shown little change during the past few weeks. Dealers are still months behind in making deliveries, and new orders are now being taken. A large proportion of the consumers are still without their winter supplies of hard coal. Bituminous is more plentiful, but it is difficult to obtain deliveries, and some dealers are taking orders only on condition that purchasers do the teaming themselves. The civic authorities announce that the order to the effect that householders whose usual supply is in excess of six tons will receive only 70 per cent. of their customary supply will be strictly enforced. Coal dealers are ordered to make returns weekly showing amount of coal on hand, orders taken and deliveries made, and if any consumer receives more than the amount to which he is entitled, the excess will be removed.

Quotations for best grades per short ton are nominally as follows: Retail anthracite, egg, stove, nut and grate, $11; pea, $10; bituminous steam, $9.25; slack, $8.25; domestic lump $10.50; cannel, $13. Wholesale f.o.b. cars at destination, three-quarter lump, $7; slack, $5.82.

BUFFALO

Rather slow movement. Anthracite still more scarce than bituminous. Reduction of shipments to Canada appear to be warranted. Cars not so scarce.

Bituminous—The trade is decidedly dull, and some shippers are getting the notion that the actual demand is not what it was. From the action of the Fuel Administration it would appear that the shortage is expected to increase, but such is hardly the appearance of the trade here. Buffalo has been hard hit by the various rulings, first by ordering coal to the lakes from the Pittsburgh district, then to New England from all available districts, then the cutting of Ohio coal out of this market, and finally the reduction of Canadian shipments 50 per cent.

Still jobbers agree that the supply to Canada has for quite a long time been better than it was with us, and especially as one proceeds eastward. Canada paid a better profit to the jobbers, and the roads there sent their cars to the mines direct and had an advantage in that, so that the anthracite consumers were able to buy bituminous to make sure of a winter supply of something, though they did not on that account abate their demand for anthracite. The situation all through is not certain, though, and the consumer is warranted in doing what he can to provide fuel.

The jobbing situation does not improve. Some members of this branch of the trade say they have not made a living since last fall, and they do not know which way to turn. They have made vain efforts to obtain closer mine connections or to buy control of mines, but with little or no success. The outlook is not promising.

Bituminous prices are for the most part made by the operator. The jobber does not venture to set up local prices, saying that it is easier to sell at mine prices and let the consignee do the rest. The added costs make the delivered prices as follows: Thin-vein Allegheny Valley, all sizes, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; smithing and smokeless, $5.60; cannel, $6.20, all per net ton, f.o.b. Buffalo.

Anthracite—The prospect of another advance in local prices sets the consumers to teasing for coal with renewed vigor, but a supply that is not over half what it was in the spring does not make any improvement possible. The shippers give no explanation, except to say that it will all come out right when the fall shipments improve. Complaints of consumers who have managed to get more than they are entitled to come in, but all the distributors can do is to shrug their shoulders and say it is a violation of the rules.

The western and northern shipments are badly curtailed, new restrictions still coming in, so that if consumers in that direction are to keep warm next winter they will need to lay in some other fuel. This state of things does not apply to the lake trade, which is pretty well kept up, though it is plainly the plan not to ship as much by that route as was shipped last season.

Lake shipments have made a spurt to 130,000 tons for the week, of which 22,800 tons cleared for Duluth and Superior, 16,000 tons for Fort William, 40,800 tons for Chicago, 41,700 tons for Milwaukee and 9 00 tons for Green Bay.

Lake coal freights continue at 48c. to Duluth, Fort William, 50c. to Green Bay, 55c. to Milwaukee and 60-65c. to Chicago.

DETROIT

Inadequacy of domestic fuel supply continues a troublesome feature of the Detroit market. Manufacturers' appeal to Federal authorities brings no increase in allowance of anthracite. Lake trade shows slight shrinkage.

Bituminous—While shipments of bituminous coal into the Detroit market make a fair aggregate, the tonnage is not greatly larger than is required for supplying the present needs of the steam coal users. There is little stock in excess of these requirements that can be utilized in increasing the factories' reserve piles. For the present, however, interest centers largely in the matter of coal for household use. With the domestic consumers of Detroit allowed only 601,000 tons of anthracite and dependent almost wholly on bituminous to offset not only a 24 per cent. reduction in supply of anthracite but the loss of smokeless and coke as well, the conditions are creating much uneasiness not only among the coal trade but among the household consumers.

In a survey made under direction of the Detroit Board of Commerce it was revealed that approximately 88 per cent. of the population of the city are still unprovided with winter fuel. Even were coal coming into Detroit in much greater quantity than it is now, it is doubtful if satisfactory distribution to all those without coal could be effected before the actual need for its use arises. With shipments holding their present volume the distribution problem is greatly complicated.

Anthracite—Disappointment was the most prominent result of the trip to Washington of a special committee of Detroit manufacturers to urge on the Federal authorities the importance of increasing the city's allotment of anthracite. The committee, headed by J. J. Crowley, president of the Detroit Board of Commerce, and accompanied by W. K. Prudden, fuel administrator of Michigan, made its appeal to the Federal Fuel Administration, to the Railroad Administration and to representatives of the War Industries Board, but was told an increase in the city's allowance of anthracite would be impossible. A promise was given by the Fuel Administration that efforts would be made to have a larger amount of domestic bituminous sent forward to Detroit during the next month. The larger part of the bituminous arriving at present consists of mine-run. This, it is said, cannot be used to advantage in the hot air furnaces, which are the only heating equipment of hundreds of Detroit homes.

Lake Trade—Various conditions have combined to bring about a shrinkage in the volume of coal being moved over the lake routes. Ore carriers delayed in thick weather were slow in unloading, reducing tonnage supply early in the week. Loading for the week is likely to fall short of 1,000,000 tons of cargo coal.

COLUMBUS

The major portion of the efforts in the coal trade now put forth are used in getting a sufficient tonnage to the Northwest in order to tide over the winter. There is a strong domestic and steam demand.

The coal trade in Ohio is now wholly at the mercy of the priority order issued by the Federal Fuel Administration. Exceptions to the ruling are appearing almost every day, and as a result there is a fair tonnage moving to public utilities and essential industries. But on the whole the greater efforts are being made to secure 28,000,000 tons for the Northwest before the winter closes lake navigation. In the meantime the steam and domestic demand can be cared for only out of the leavings, so to speak.

The movement to the Northwest has now reached a high level. The vessel movement is generally efficient and practically no time is lost at either end of the journey in loading and unloading. The ore movement is good. In some instances lake vessels are going up light, but such cases are quite rare. Reports show that the coal is moving off the docks of the upper lake ports quickly, and there is no congestion to hold up traffic. The tonnage is still considerably behind pre-season estimates and supreme efforts will be required to fill the requisitions. Lake prices are strong at Government levels.

The steam business is rather quiet, due to the operation of the priority order. A considerable quantity of screenings is coming into the Columbus market as the lake trade produces it. But it is only due to large surplus stocks accumulated earlier in the season that there is not considerable shortage of coal among manufacturing plants. Public utilities are being looked after with exceptions to the priority order, and the same procedure is used in the case of supplying essential industries. Non-essentials are having the worst time in securing fuel. Railroads are still large consumers as the freight movement is extra heavy.

The domestic trade is rather quiet also. Dealers stocks are generally low and they have not been able to replenish them as desired. But there is some coal in the yards of retailers and consumers are still placing orders. Generally speaking, private users have a larger amount of fuel stocks at this time than ever before, and that is a reassuring factor. Retail prices are strong at fixed levels. Practically no Pocahontas is arriving in the local trade. Some West Virginia splints are received and find a ready sale.

CINCINNATI

Fair car supply, steady demand and some removal of domestic pressure mark the trade just now. Lake movement is in full swing.

The movement of coal through this gateway to the Lakes, as well as to points north, continues in a steady volume, aided, as to the Lakes, by the operation of the priority order, giving preference to cars loaded for the ports. The car situation is not so good as could be desired, although on one or two roads it is better than on others. Receipts of new cars, the result of the large contracts let by the Government, have not yet begun to exercise any perceptible effect on the enormous demand for rolling stock, and production, while below the maximum demand now fully in evidence, will probably continue for some time to be in excess of the ability of the railroads to handle. One favorable sign is that the retail trade seems to be fairly well taken care of, indicating that the heavy storage demand from domestic consumers, which has been pressing all summer, has been to a large extent satisfied, and that, accordingly, there is little danger in this immediate section of any serious domestic shortage of fuel next winter. However, it is of course the large industrial consumers who have most cause to worry, especially those whose operations cannot be classed as essential to the conduct of the war. It is probable that many such concerns will find it necessary to suspend operations next winter, as it is virtually certain that there will not be enough coal to supply all industrial and domestic requirements, and the non-essential industries will consequently be left, literally, in the cold.

LOUISVILLE

Car shortage more serious during the past week, with labor supplies considerably under needs of mine operators. Jobbers having considerable trouble in securing coal. Retailers meeting with good demand for domestic, but making prompt deliveries. No yard stocks accumulating, but plenty of steam coal on hand.

Conditions at the mines have been worse during the past few days than for some

time past, due to the fact that cars are so scarce that mines in western Kentucky have been forced to close down half and full days at a time awaiting an unsteady supply of cars. The present shortage of cars is largely due to the heavy movement of coal from the Virginia-Eastern Kentucky district to the Lake region, which is keeping cars on the road for long intervals, either under load or returning empty, resulting in additional supplies of cars moving into that district, and cutting short the supply for western Kentucky. Even the eastern Kentucky district is short of cars at the present time.

Retailers have caught up fairly well with domestic stocking orders, and are now making prompt deliveries, in some cases deliveries on the same day that the order is placed. However, the domestic demand is taking care of all the coal delivered on the market, and no yard stocks are accumulating. Practically all stocking is on western Kentucky coal, and some little Hazard coal, but all eastern Kentucky, Straight Creek, Jellico and other good grades are now moving to the lakes, with the result that the better grades are practically unobtainable for domestic consumption, and even concerns which can not burn low grade coal are having trouble in securing supplies. The steam demand has been fairly active, but steam coal has been accumulating to some extent. A number of old contracts have been renewed of late, and with heavy expirations of contracts in September and October, the steam outlook is promising.

Jobbers are having much trouble in securing supplies of coal, as eastern Kentucky coal is unobtainable, and the western Kentucky mines are being offered more business than they can take care of, with the result that the jobbers cannot find supplies of any moment.

BIRMINGHAM

Coal production falls below tonnage of previous week. Manpower at mines seriously affected by draft. Car supply also inadequate to insure full time operations at some points. Demand for steam and domestic holds up well. No surplus coal available.

The output of coal in the Alabama field for the week ending Aug. 17 showed a loss of 16,000 net tons over the previous week's record of 427,000 tons, according to figures tabulated in the office of District Representative E. A. Holmes. This loss can be attributed to three causes—failure of labor to work full time, shortage of labor, and inadequate supply of equipment for loading coal. The draft is taking many men away from the mines and paydays during the past week caused the usual resultant idleness.

As regards market conditions, trade is brisk in both steam and domestic sizes, and consumers of a nonessential character are having difficulty in securing a fuel supply. Domestic coal is being stored as rapidly as conditions of supply will admit, and the past few days of fall-like weather will likely accelerate the buying movement, if such be possible.

Coke

CONNELLSVILLE

Labor conditions slightly better. Connellsville coal for byproduct ovens. Screenings from dumps increased. Coke production about stationary.

Oven labor conditions appear to be somewhat more satisfactory, but the drain of coal from the Connellsville region to operate byproduct ovens recently completed is such that beehive ovens are hardly able to maintain their former rate of production, which in April, May and June was about 340,000 tons a week and in July rose to about 350,000 tons. As matters are now aligned an output of about 325,000 tons a week seems to be in prospect, but as more byproduct ovens are completed it is possible that this may be reduced. The change in point of coking is of course only by the producer-consumer class. The merchant ovens in the region are making fully as much coke as formerly.

Allocations of surplus coke, or coke that might possibly become surplus, continue to be made, and the appearance of any furnace coke in the open market is practically prevented. Offerings of foundry coke continue relatively free and the supply appears to be not only adequate to current consumption but to afford an opportunity for some foundries to stock coke against the winter.

Production of screenings from old dumps, chiefly for household use, continues to increase, partly by reason of new undertakings and partly by reason of a slightly better labor supply. When not under 3-in. and properly prepared this material would be permitted a price of $7.30, the price set for such coke in general, but on account of appearance the material must necessarily go at a discount, and $6.50 is about the highest price obtained. Even at the increased rate of preparation the dumps are expected to last the year out.

The market remains quotable at the regular set limits; Furnace, $6; foundry, 72-hour selected, $7; crushed, over 3-in., $7.30, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Aug. 17 at 326,610 tons, an increase of 7600 tons.

Buffalo—The coke trade is easy as regards the supplies of ore and flux, but as difficult as ever as to the supply of coke itself. The furnaces are in as close touch with the coke ovens as they can be, and that is their salvation. The supply is never adequate, but it manages to answer in some way and all the furnaces are able to keep running. In the ore trade all is booming. Lake receipts for the week were 330,376 gross tons, a good season's average, which is likely to keep up. Every effort is made to keep up the output of the byproduct coke ovens in this district, but the new plant building by the Donner-Union Co. in the city does not promise to be in running condition this year.

Middle Western

MILWAUKEE

Dealers looking for an advance in soft-coal prices, and possibly in anthracite, on Sept. 1. Supply outlook good.

There have been no new developments affecting coal prices at Milwaukee since the recent advance of 40c. per ton in anthracite grades. State Fuel Administrator Fitzgerald is in Washington, ostensibly to confer with the National Fuel Administration concerning priorities to the Northwest, but dealers are expectant that when he returns he will bring orders for an advance in bituminous coal, and possibly the customary September lift in anthracite.

Before leaving, Mr. Fitzgerald made Milwaukee's colony of florists happy by giving them permission to use 100 per cent. of their fuel needs provided screenings are utilized. Heretofore they were permitted to use only 50 per cent. of their actual needs and were denied anthracite absolutely. This order is taken to indicate that the demand for some grades of coal is not taxing the supply to the utmost.

From present indications Milwaukee is safe from a serious coal shortage. Consumers will have to be satisfied with most any grade of coal, however, and everyone must practice economy in fuel consumption.

Since last week's report coal receipts aggregated 27,993 tons of anthracite and 204,951 tons of bituminous. The season's receipts thus far, according to the latest revision, foot up 306,863 tons of anthracite and 1,882,720 tons of bituminous.

A Vesper, Wis., brick manufacturing concern has decided upon an investment of $500,000 to develop Wisconsin peat beds. Experts hold that a good quality of coke can be produced from peat, as well as the regular coal byproducts, such as gas, ammonia, etc. Wisconsin peat beds are almost inexhaustible and represent a potential saving in coal of millions, according to expert calculation.

ST. LOUIS

An unusually quiet market on everything. Domestic orders practically stopped. Steam coals heavy. Severe car shortage. Poor transportation keeping prices up. Country demand poor and extreme warm weather interferes with business.

The local situation is one that is considerably hampered by the continued hot weather. The local coal business is practically at a standstill. Orders have stopped coming in, and the yards are making poor deliveries. The labor shortage is interfering with the deliveries in a retail way and this threatens to become a serious matter in a short time.

During the past week Fuel Administrator Crossley, in conjunction with the St. Louis Fuel Committee, has put on inspectors to keep a record of the employees of coal companies, with a view toward reporting them to the police authorities as idlers if they do not continue to work.

There is a fairly good demand in a domestic way for Carterville coal, but it is extremely hard to get. The local steam demand is not anywhere near what the mines have to offer, and the Chicago market is not absorbing steam sizes in sufficient quantities to keep the prices anywhere near the Government maximum. If it were not for the railroads the market would be glutted.

A fairly good tonnage from the Standard field has moved to Michigan. This, however, has been for the most part screened coal and 6-in. mine-run. The operators hesitate to ship too much of their coal there for the reason that it would create a car shortage here. This is already apparent.

The Louisville & Nashville is furnishing equipment for about one-half time and the Iron Mountain has mines that for five to six days straight have no equipment. The Illinois Central is in bad shape and also the Missouri & Ohio. The road that suffers mostly in car shortage and in transportation is the Iron Mountain.

In the Carterville field the mines have had some relief in the way of water, three or four heavy rains taking care of that temporarily. The supply of electricity from the Public Service Co. still continues to keep many mines idle a portion of the time. Labor is dissatisfied and the operators much discouraged.

A heavy tonnage of this coal still continues to go for railroad purposes, the Fuel Administration apparently falling down in its efforts to divert it to the channels where it could be used to better purpose. Offsetting this is the surplus of coal in the Standard field that the railroads could well take care of. Similar conditions continue in the Duquoin field. The labor shortage here is severe.

The Mt. Olive field still continues to be nearer normal than any other field in the state. Car supply is fair and so is the labor problem. There has been a scarcity of water that affected some of the mines to some extent. The movement has been good and the demand about equal to the production. A good tonnage of this coal is also going to railroads.

In the Standard field some mines on the Illinois Central have been idle for three days straight on account of no cars. Mines on the Louisville & Nashville are working about three to four days a week on account of no equipment. Cars are short on the Missouri & Ohio.

The distribution of cars on the Illinois Central seems to continue to impose unfair conditions upon some mines. There is a surplus of practically all grades of coal in this field, and in the past week some mines were idle rather than work and have coal unbilled. This covered all sizes, and this condition exists at this time.

To relieve this condition Lieutenant-Governor Crossley secured a ruling from Washington that restrictions on all industrial plants in the matter of storage coal would be lifted until Sept. 10, permitting them to store such coal as they wanted for the present and the future of screenings and low grade coal. Western Missouri could use a large tonnage of this coal if the zone restrictions were removed.

In the matter of gas house domestic coke the St. Louis Fuel Committee's contention is that the local price should be based upon the price of deliveries and $6 f.o.b. ovens with the rate from the Earlington-DeKoven field in western Kentucky, which is $1.70. This reduces the wholesale price of coke for the dealers f.o.b. the ovens in St. Louis from $9.60 to $7.70.

There is no change in wholesale prices and all coal is taking the Government maximum excepting Standard 2-in. lump, which is around $2.40 to $2.45, and screenings, which are going at from $1.55 to $1.60. The prevailing market price per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....
No. 3 nut	2.55@2.70	2.55@2.70	.....
No. 4 nut	2.55@2.70	2.55@2.70	.....
No. 5 nut	2.05@2.20	2.05@2.20	.....
2-in. scrgs	2.05@2.20	2.05@2.20	1.25@1.50
3-in. lump	.....	.....	2.25@2.40
2-in. lump	.....	.....	2.25@2.40
Steam egg	.....	.....	2.25@2.40
Mine run	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1	2.75@2.90	2.75@2.90	.....
No. 2	2.75@2.90	2.75@2.90	.....
No. 3	2.55@2.75	2.55@2.75	.....
No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

COAL AGE

Volume 14 New York, September 5, 1918 *Number* 10

The Heroes of the Pick

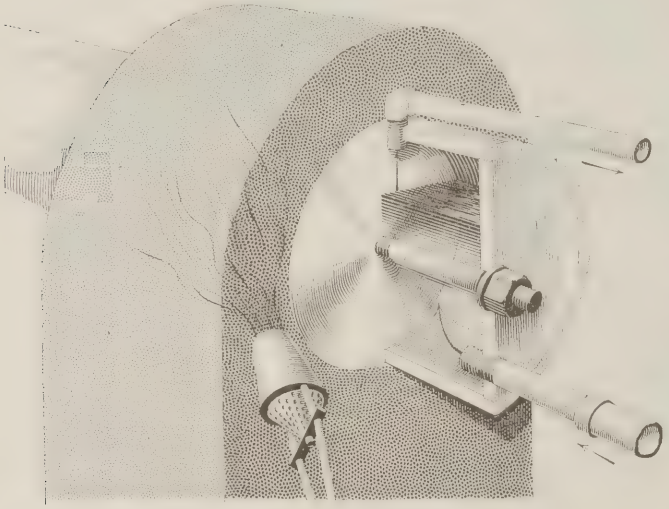
By Rufus T. Strohm

Written Expressly for COAL AGE

THEY had drawn away from the heavy toil
And dropped the drill and the miner's lamp;
They had grown unused to the smell of oil,
The powder reek and the sultry damp;
For there wasn't one but had passed his prime,
And work seemed more than their frames could bear,
So they swapped the sweat and the sooty grime
For the soothing pipe and the easy chair.

BUT the war came on, with its vast demands
For guns and shells and the men to fight,
And the mines were stripped of the youthful hands
That took up arms in the cause of Right;
Then the old graybeards who had quit the race
And stood aside for the younger men
Traveled back once more to the working face
And bent to their old-time tasks again.

FOR the country's need in the dismal strait
Was great as the skillful hands were few,
So they scorned to load, and they would not wait
But did the thing that they best could do;
And their wrinkled faces were freshly scarred
By falling coal and by flying chips,
And their twisted fingers grew rough and hard
From clutching long on the shovel grips.



THEN here's to the veterans of the mine,
Whom age nor weakness could hold in thrall,
But who manned the gaps in the working line
When youth had answered the bugle call;
For they give the help that the nation craves
And show the spirit that wins the day,
And they put to shame all the slacker knaves
Who dare to do any less then they.

IDEAS AND SUGGESTIONS

Removing a Tight Crankpin

BY J. A. LUCAS
Ozone Park, N. Y.

Many difficulties arise in removing a crankpin for repairing. To do this tedious job without damaging the pin I hit upon the idea shown in the accompanying illustration. A piece of pipe of the diameter of the pin was internally threaded on one end and plugged with a

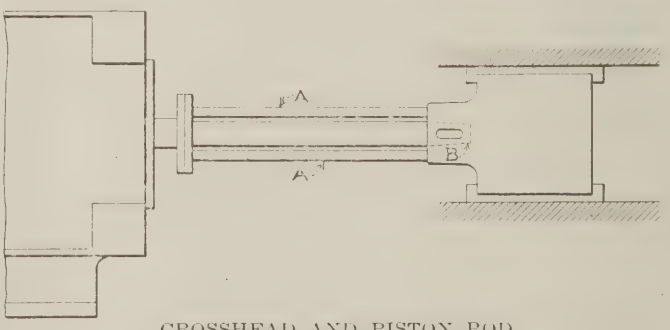
HOW THE CRANKPIN WAS REMOVED

plate, thus forming a container, which was held against the end of the pin by means of a bolt. A water inlet pipe was threaded into the bottom and an outlet at the top. While the crank arm was heated with a torch, water was circulated in the container, the circulating water keeping the pin cool. Upon heating the crank arm or disk, it expanded and the pin was then easily removed.

Slush Line Joints

Portions of anthracite mine workings for many years have been filled with the fine coal dirt and pulverized slate and rock resulting from preparation of coal in breakers. However, now and then a progressive colliery official will work out some modification of old methods which will simplify matters and save money. This was illustrated by a simple expedient adopted by the Lehigh Valley Coal Co. and noticed in operation at its Dorrance colliery, within the city limits of Wilkes-Barre, Pennsylvania.

For years the ordinary screw joint has been used on flush lines. On a long line many connections are necessary, and difficulty has often been experienced in unscrewing joints which rusted tight. Many times joints have had to be cut with a "diamond point" tool in disconnecting pipes when changing lines. This method took time and wasted material. To overcome this obstacle a simple and effective joint was devised which has given satisfaction in operation.



At the Dorrance colliery the slush material is carried into the mines down an 800-ft. borehole through a 6-in. pipe line. From the bottom of this borehole the slush is carried a considerable distance along gangways before reaching the workings to be filled. It is on this latter line that the couplings in question are made. On straight lines of 6-in. pipe, couplings consist of pieces of 7-in. pipe 20 in. long. The joint is made by driving wooden wedges in between the 7-in. coupling and the 6-in. pipe around both ends of the coupling. There is a space of about $\frac{1}{4}$ in. between the 6- and 7-in. pipe. This joint is readily made in about ten minutes.

When this kind of a joint is made, the 6-in. pipe has blank ends, the thread being omitted. A blank-end pipe lasts longer than a threaded pipe, which is weakened by the threads. To loosen this pipe coupling the wedges are knocked out and then the 7-in. sleeve is driven back with a sledge. These couplings will stand any pressure likely to be met with in practice, and they will last until a change of pipe is necessary under usual conditions. Turns in a pipe line can be made, a line bending 7 ft. in 20 ft. of length. In this case an 8-in. coupling is used in making a joint. *Coal Age* is indebted to the courtesy of H. Price, the inside foreman at the Dorrance colliery, for information in regard to the slush joint described.

Crosshead Removed by Heating

BY A. J. CAHEN
Brooklyn, N. Y.

Some time ago a 500-hp. engine of the Corliss type was to be dismantled, and it was found impossible to remove the crosshead from the piston rod by any of the customary methods. The end of the rod *B* was a taper fit in the head, as indicated in the accompanying draw-

CROSSHEAD AND PISTON ROD

ing. After several schemes were tried and abandoned, I decided to utilize the principle of expansion and contraction of metals under the action of heat and cold, and arranged as follows to get the head off the rod.

In the drawing the rod and crosshead are shown with the rod projecting its maximum distance from the cylinder, which gave a measurement between the end of the crosshead and the face of the stuffing box gland of about 6 ft. A gasoline torch was applied near the

middle of the length of the rod, where a sheet-steel hood had been arranged. Although various observers had prophesied that it would be impossible to heat the rod sufficiently in this way to cause it to expand appreciably, nevertheless, after application of heat for some little time, the length of the rod had increased as much as was required for the purpose.

After the rod was heated a measurement was taken between the face of the gland (which was backed up against the stuffing box after the packing was removed) and the inner end of the crosshead. According to this measurement a pair of steel shafts were squared off slightly longer than it was supposed they would be required. These were placed as at *AA*, on opposite sides of the piston rod between the crosshead and the stuffing box, where they were supported upon a suitable frame. Cold water was then poured on the hot piston rod and the instant it commenced to shrink it pulled the crosshead snug against the ends of the shafts and a moment later the crosshead was forced free.

Alarm Bell on Mine Car

By Matthew Stafford
Chase River, Vancouver, B. C.

In many mines the main haulage road is also used as the traveling way on account of it's being the intake and it is desirable to allow the men to travel in fresh air. There are, however, other local causes. Traveling on the haulage roads—especially when the trip is running—involves an element of danger that every miner realizes. This is enhanced when the road is used for main and tail haulage, and it is for this special system that I wish to suggest an improvement that I think would be appreciated.

There are certain parts of these haulage roads where the trip is running the rollers and the drums make a noise, similar to that of a running or approaching trip. This causes the men and boys to run to the nearest manhole or squeeze themselves against the side. After a short period of waiting they step out thinking they have been fooled, probably only to get the scare of their

DETAILS OF ALARM BELL

lives with the real article in the shape of the trip suddenly coming upon them. We all know the safest plan is to strictly prevent men from traveling on the road while the trip is running, but sometimes this plan is evaded.

What I would like to suggest would be the placing of a good sized bell attached to a spring and made to fit on the front car of the trip—either full or empty—by two properly shaped hooks to prevent its toppling over. The top of the bell and the spring should be no higher than the top of the car. I think this would be in line with the safety movement that is doing much good in the prevention of accidents.

Duty and Destiny

IT is not every man who realizes that as he goes his way his destiny accompanies him. And the man who has learned that duty and destiny are inextricably woven together is as unusual as he is fortunate.

There is getting to be small place in the world today for the man who cannot see his plain duty and recognize the fact that his own and his country's destiny depend on his performance of that duty. It is a fine thing that hundreds of thousands of coal miners are learning to express the product of their labor—not in terms of net tons, but in terms of guns, shells and ships. For a miner to know that four shovelfuls of coal mean a 3-in. shell for his brother or son to shoot at the Hun is the best possible way for him to see his duty and the destiny of his family, self and country. And when all the miners in America begin to dig coal on the basis of a 3-in. shell for every four shovelfuls of coal, it won't be long 'till the boys "over there" will have finished what they set out to do.

WE have a national duty, too, that is growing clearer and plainer to all — America must use her forces to the limit to crush German kultur as quickly as possible and thus make life, rather than death, the destiny of millions of men; for the best opinions are that a long-drawn out war would suit the German plans better than anything else—for the German believes that war is the chief business of man.

Where is the man who cannot see his individual duty in the face of a national duty like this? If there is such a man in the mining industry, he can only fail to see his duty by looking through the glasses of ignorance or blind prejudice. He will do well to remember that there will be a sorry destiny for the man in America who cannot see his duty in this day and time.

DUTY is a sublime word because it means work and service. there are many ways of gaging the size of a man. You may find his intelligence by examining his brain. Better still, you may find the kind of man he is by looking into his heart. But nowadays you had better look up and down his backbone to see if he means to do his full duty to his country and its allies, by aiding them in working out the destinies of free men in the world.

To the man who is so fortunate as to be a skilled coal miner, a motto is offered for the duration of the war:

I Am a Coal Miner.
I Can Produce 300 *3-Inch Shells a Day.*
I Ought to Produce 1800 *Such Shells a Week.*
I Must Do All I Can to Crush the Hun.
I Will Do My Duty.

THE coal miner who lives up to this will never need to have a fear about his destiny. It will take care of itself.

COAL MINERS OF AMERICA—Your wills are your own, and your wills are your masters. The destiny of thousands of good men at the front is in your hands. It is up to you to make answer.

Simpson Creek Coal Co.'s Tipples

By R. G. READ
Chicago, Ill.

SYNOPSIS — *Many novel features are embodied in the design of these tipples. The coal coming down the mountain side instead of consuming power generates it. Falls, and consequent degradation of coal, are carefully avoided so far as possible throughout the entire design.*

THE fundamental consideration governing the design of tipples Nos. 2 and 3 of the Simpson Creek Coal Co., at Galloway, W. Va., was the saving of power and labor for operation. Contrary to the general practice of using a retarding or drag conveyor where the coal is to be delivered for loading to a lower level than the mine, a conveyor of the apron type was used. By this arrangement the potential energy in the coal due to the action of gravity was utilized instead of being wasted, together with the additional power required to actually drag the coal down the hill. The topographical conditions were particularly favorable to the working out of this idea in these installations.

Fig. 2 shows the general arrangement of the No. 3 tipple, the No. 2 being substantially the same except that the conveyor is shorter and on a uniform pitch. The trip of 80 cars, containing 2¼ net tons of coal each, is delivered to the tipple by a chain car haul. A Phillips crossover dump delivers the coal to a hopper, from which it is fed by means of a reciprocating feeder to the apron conveyor, which discharges it onto the gravity screens.

The empty cars are kicked back onto a car-haul tripmaker which elevates them to the level of the loaded track and pushes all preceding cars out onto the empty track, so that the trip is made up mechanically. The loaded car haul has an adjustable capacity of three to five cars per minute, and is so located with regard to the scales that each car comes to a stop while being weighed. The driving machinery is located in a concrete pit below the floor, an idler sprocket being used in order to gain headroom around the machinery. The reciprocating feeder is provided with an adjustable-stroke crank and an adjustable-speed motor. The discharge end of the feeder plate is perforated so as to allow the fine coal to drop through, providing a cushion for the lumps. This also makes a partial separation for picking on the conveyor when desired.

The conveyor is 48 in. wide, of the long-pitch apron type, mounted on two strands of bushed roller chain with inclosed-oiling, chilled-tread rollers. The drive is placed

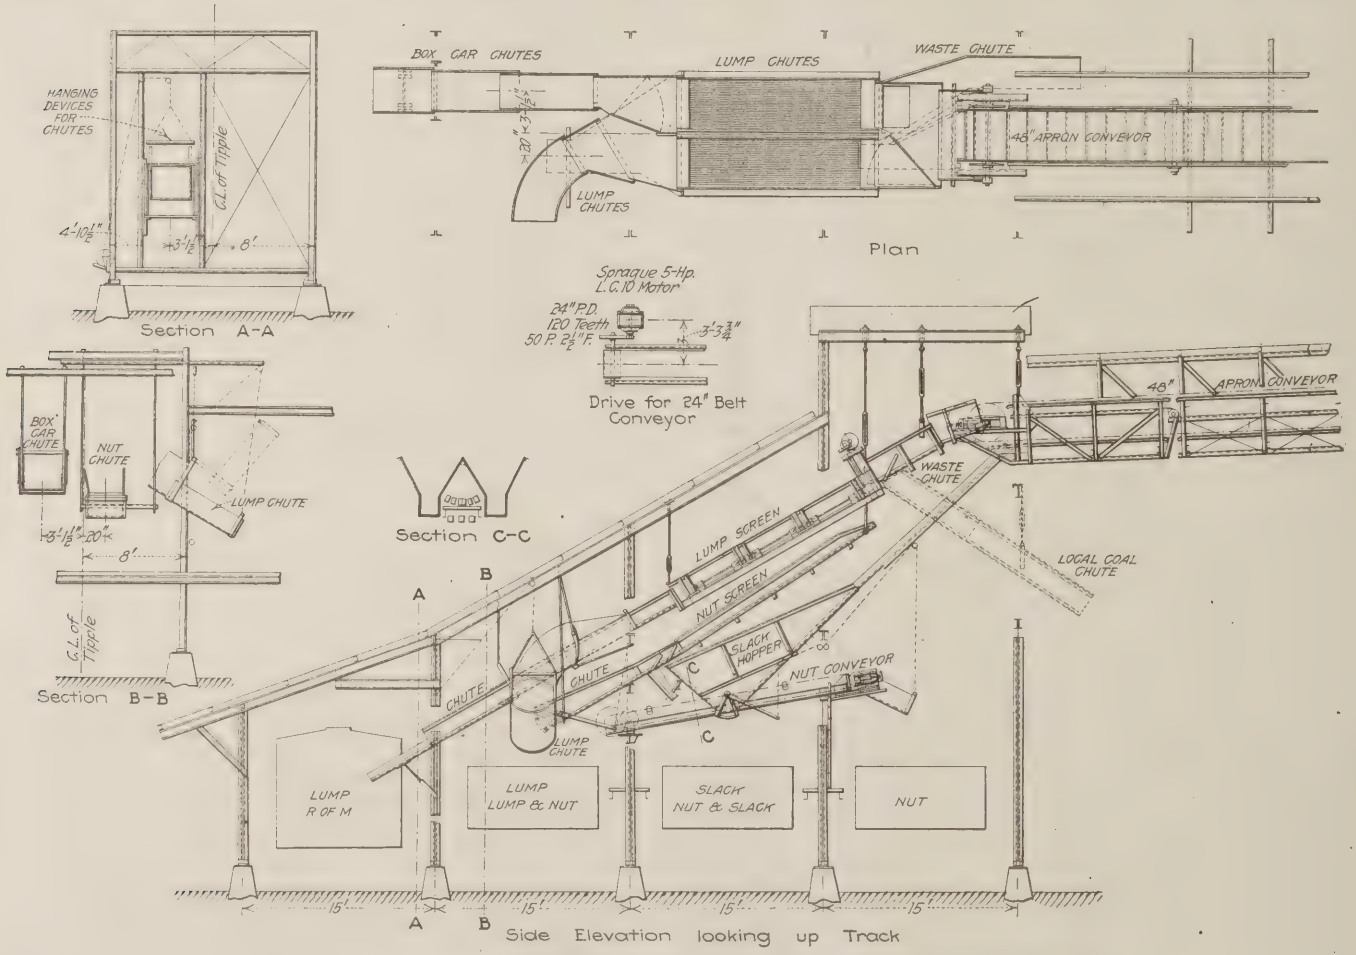


FIG. 1. ARRANGEMENT OF SCREENING EQUIPMENT IN THE TIPPLES

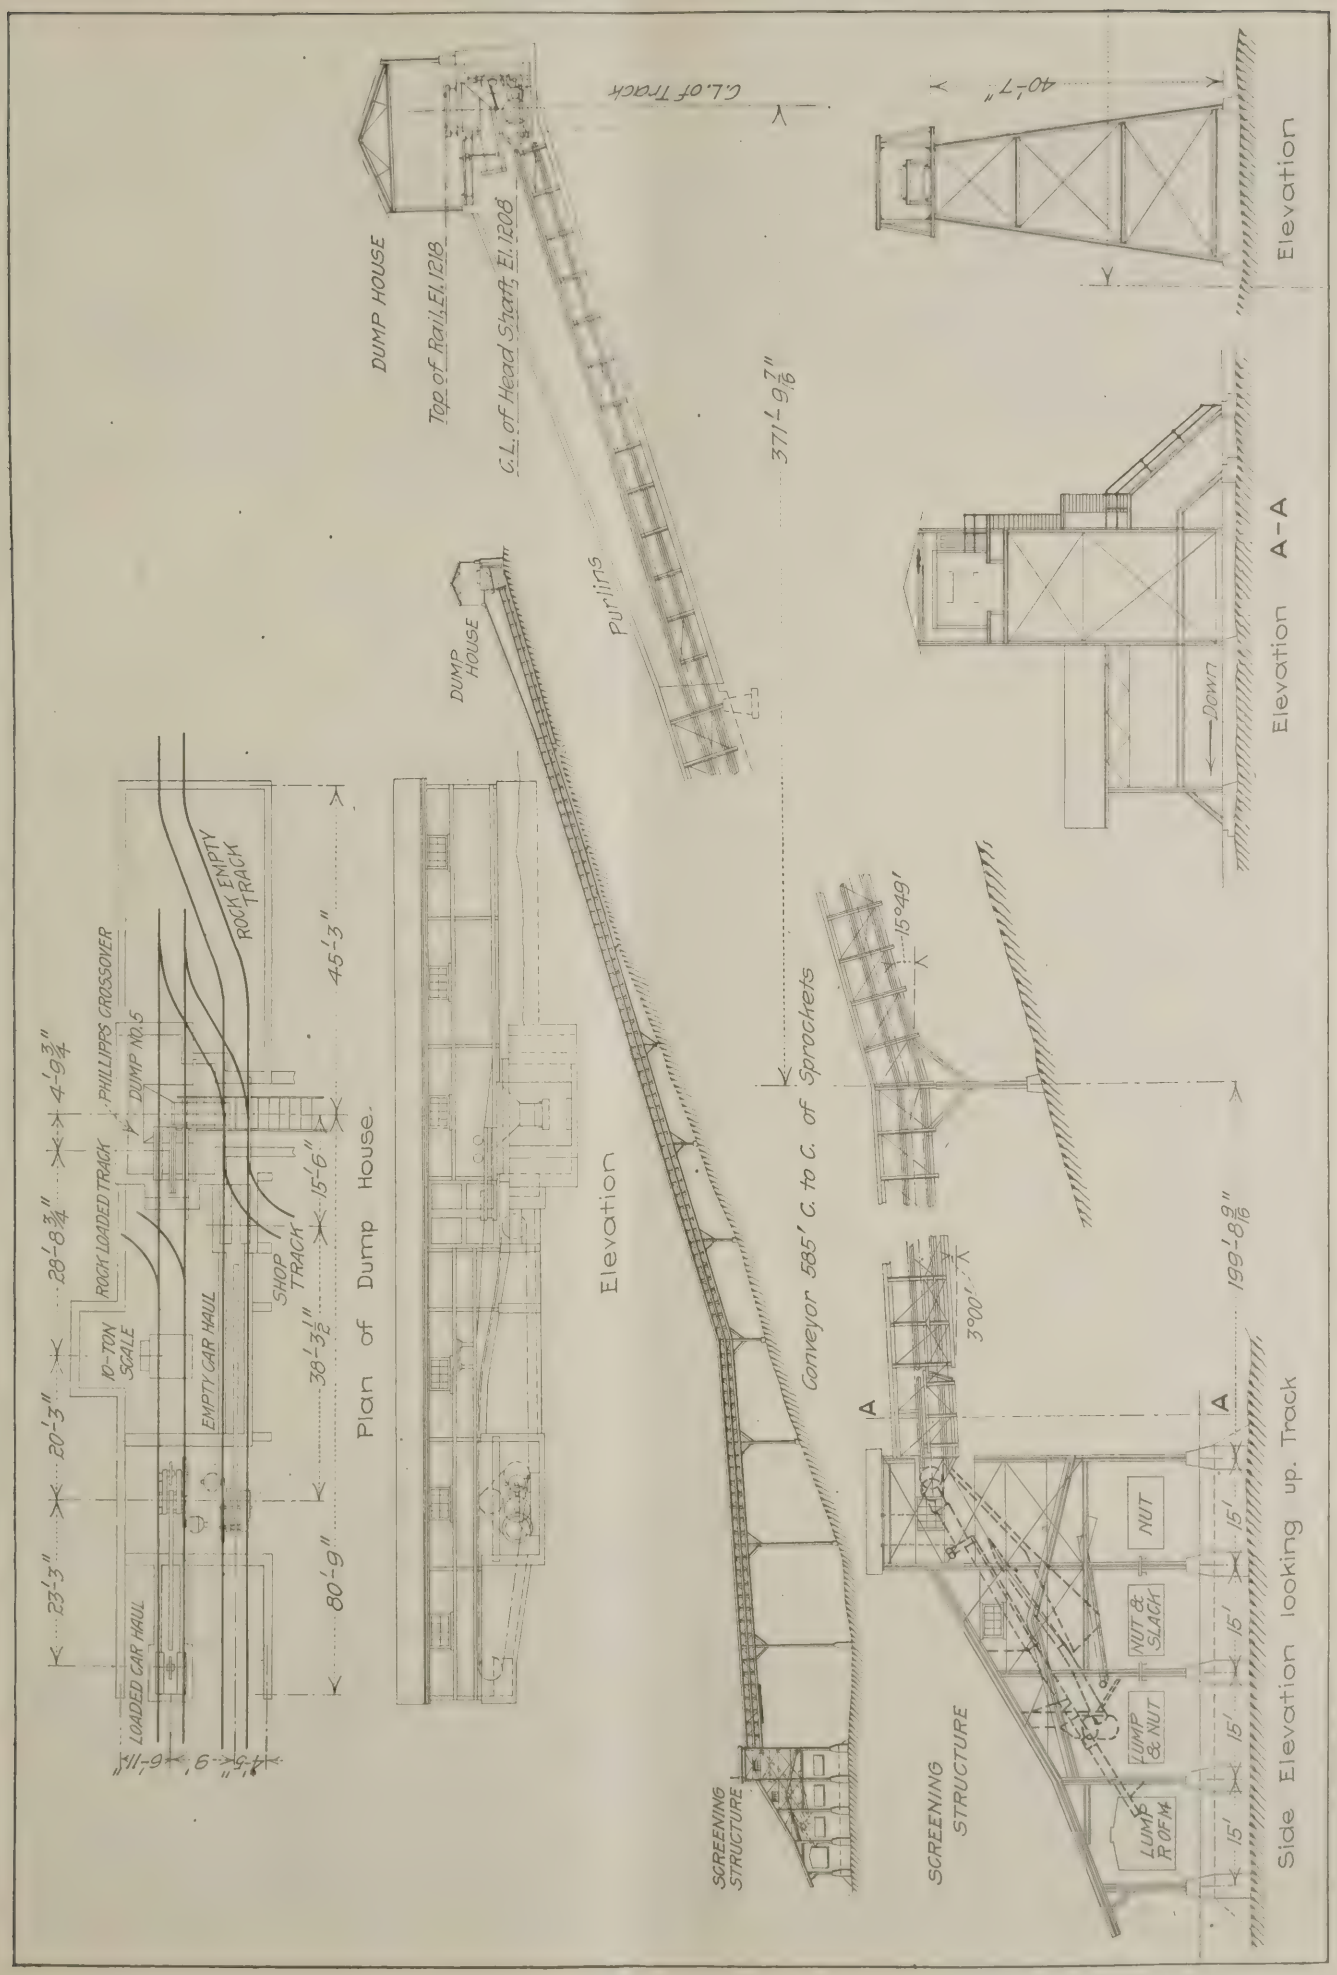

FIG. 2. GENERAL ARRANGEMENT OF NO. 3 TIPPLE, DUMP HOUSE AND CONVEYOR LINE

FIG. 3. DISTANT VIEW OF NO. 2 TIPPLE, DUMP HOUSE AND CONVEYOR LINE

at the head end, all machinery being mounted on a self-contained steel frame on concrete foundation. The take-up is located at the lower end and the pitch of the conveyor on the flatter portion is sufficient to run the line when loaded, so that no power is applied through the take-up shaft.

A 20-hp. adjustable-speed motor is geared direct to the drive shaft. This motor starts the conveyor empty, and as the conveyor becomes loaded the power taken becomes less and less until the motor is finally run as a generator with an output of 30 hp., which is returned to the line. A magnetic brake attached to the motor holds the load when the motor is stopped. The control is of the remote push-button type with magnetic acceleration. A push-button station for starting and stopping is operated by the dumper, and a stop and safety (no start) station is located on the trimmer's platform in the tipple.

The discharge end of the conveyor is carried on a pivoted frame so that the screens can be adjusted without increasing the drop of the coal. The discharge chute is connected to the take-up shaft and moves with it, thus maintaining the proper relation between the two. The speed of the conveyor may readily be adjusted to travel from 50 to 90 ft. per minute.

Fig. 1 shows the arrangement of the screening equipment. Contrary to accepted practice, the point of discharge to the railroad car was considered as the basic point rather than the discharge onto the screens. The entire screening equipment, including the discharge of the conveyor, is adjustable, so that any reasonable pitch can be secured without increase in breakage. The point of discharge to the car is also adjustable within reasonable limits.

The principal requirements in this installation are the loading of large quantities of thoroughly screened ¾-in. lump and run-of-mine in open and box cars, and the loading of slack in open cars. It is also necessary at times to load nut coal in open cars. It will be noted that the design is such as to accomplish the main purposes with the minimum of uncontrolled travel of the coal in the chutes. The usual position of the nut and slack tracks is reversed, and the nut coal is conveyed to avoid increasing the height of the discharge of the conveyor which would be necessary in order to make a gravity distribution of the nut. Special attention was given to the design of the main loading chute, so as to make the loading apron sufficiently easy of operation to insure its being used. This means the minimizing of the drop of the coal into the car.

FIG. 4. GENERAL VIEW OF NO. 3 TIPPLE AND CONVEYOR

The veil plates on the lump screens are electrically operated, a separate motor being used for each of the two sets. These are made up of three sections each. Each screen has a surface of 4 x 16 ft., and by using different combinations of the veil sections it is possible to adjust the screening to the actual requirements for inspection of the coal. The design of the veils is such as to permit of their being lowered without the necessity of removing any small lumps which may be lodged between the screen bars.

The box-car loaders are of the pivoted truck type known as Model 3C Christy. These are particularly suited to the requirements of this installation. Domestic coal is taken care of by a steel tank in connection with the No. 2 tipple. Both tipples are of steel throughout, and the roofing and siding are of asbestos protected metal.

The control of the motors is of the remote type with magnetic acceleration operated by push button. Each motor is provided with a field rheostat for adjusting the speed. A 25 per cent. series winding is provided for

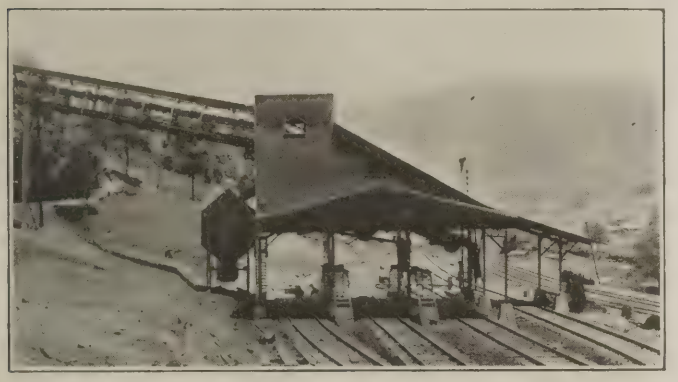

FIG. 5. NO. 2 TIPPLE AND DOMESTIC COAL TANK

starting. This is automatically cut out when the motor reaches full speed, after which it operates on straight shunt winding.

Fig. 4 is a general view of the No. 3 tipple. Fig. 5 shows the No. 2 screenhouse and domestic coal tank, while Fig. 3 presents a general view of the No. 2 tipple. Each tipple has a normal working capacity of 500 tons per hour, but a much larger output could be handled should necessity require.

The entire equipment was designed and furnished by the writer, and the conception is original. The construction work was carried out by Elkins Read. The Simpson Creek Coal Co. owns 3100 acres of the Pittsburgh seam, which is exceptionally thick and free from impurities. J. W. Galloway is president of this company, J. E. McGowan, secretary and treasurer, and David Williamson, vice president and general manager.

A New Mine Mule

A new wrinkle in the solution of transportation problems for small mines, quarries, sand pits and operations of such character is worthy of attention, and more especially at this time, when the nation-wide cry is for more coal. At a time when the labor market is drained the only solution in answer to such a cry is by the greatest possible adaptation of all mechanical means for the speeding up of production.

A step in this direction, the importance of which is apparent upon short consideration, is the recently perfected Leathers mine motor now being built by the L. A. Leathers Co., of Brookville, Penn. About a year ago this concern built the first motor as an experiment, in an effort to eliminate the use of mules on a long outside haul at a mine too small to warrant the installation of a power plant or the purchase of the more expensive type of mine locomotives. The experimental motor was built by mounting a Ford chassis on a substantial white-oak truck fitted with flanged wheels for use on the mine track. Several features have been added to eliminate some of the inherent automobile characteristics not suitable for mine haulage.

After a year of continuous service the motor is giving most excellent satisfaction, and the mine tonnage has been tripled, being raised from 50 to 150 tons per day. For the small mine operator, so many of whom have commenced operation during the past two years, this haulage innovation should prove a godsend. It not only enables an increased production, but at the same time eliminates mules on the long hauls by the substitution of a motor obtainable at a low first cost and which can be operated at all times on outside haulage as well as in any mine entries in which the ventilation is suitably arranged.

Best Weather-Resistant Paint

The best paint to resist weather is one made from pure linseed oil combined with pigments of permanent color and high protective quality. Linseed oil cannot be adulterated and yield best results in a paint; thinners and dryers are not, however, adulterants. The popular belief that white lead is the best procurable body for a paint is rapidly being disproved by the employment of other and better pigments or mixtures of pigments. Science has made possible improvements in paint making just as it has in the other branches of human endeavor.

"Slacker Boards" in West Virginia

In an effort to stimulate coal production, what are known as "slacker boards" have been erected at each of the 15 operations of the New River Co. in Kanawha and Raleigh Counties. The slacker board is a large blackboard appropriately lettered so that the result of the day's work can be filled in the blank spaces and read at a glance. Among other things the board gives the allotted tonnage, tonnage produced for the day, number of men working, number off, hours worked, names of men not working, etc. These boards will be conveniently placed near the company offices where the men can readily see them and see what they have accomplished for the day.

Another innovation of the New River Co. is the daily posting of Associated Press bulletins at each of the operations giving the latest war news each day. In connection with the war it may be interesting to state that to manufacture ammunition for one hour's bombardment on a one-mile front requires 7000 tons of coal. Thus it will be seen why every effort is being made to speed up the production of coal and why the war department has ordered that no more miners be enlisted.

Large Underground Synchronous Substation

By R. P. HINES
Fairmont, W. Va.

SYNOPSIS—*An increasing load growing ever more remote rendered the installation of a transforming and converting station underground advisable. This has now been in use for many years with marked advantage in operation and has given entire satisfaction.*

IN VIEW of the discussion, pro and con, on the subject of underground substations, which took place in the columns of *Coal Age* some months ago, it was thought that a description of such an installation that has proved its worth and reliability by years of continuous service, together with certain other features connected with its development, would perhaps prove of great interest to many readers. It is with this hope in mind that this article has been prepared.

The coal-mining development where this substation is installed is located in the bituminous coal field of Somerset County, Pennsylvania. The coal being mined is what is locally known as the C Prime seam. The company operating this development has various other mines in the same region, and a central steam-electric generating station has been installed, from which power is transmitted to the company's operations in the vicinity.

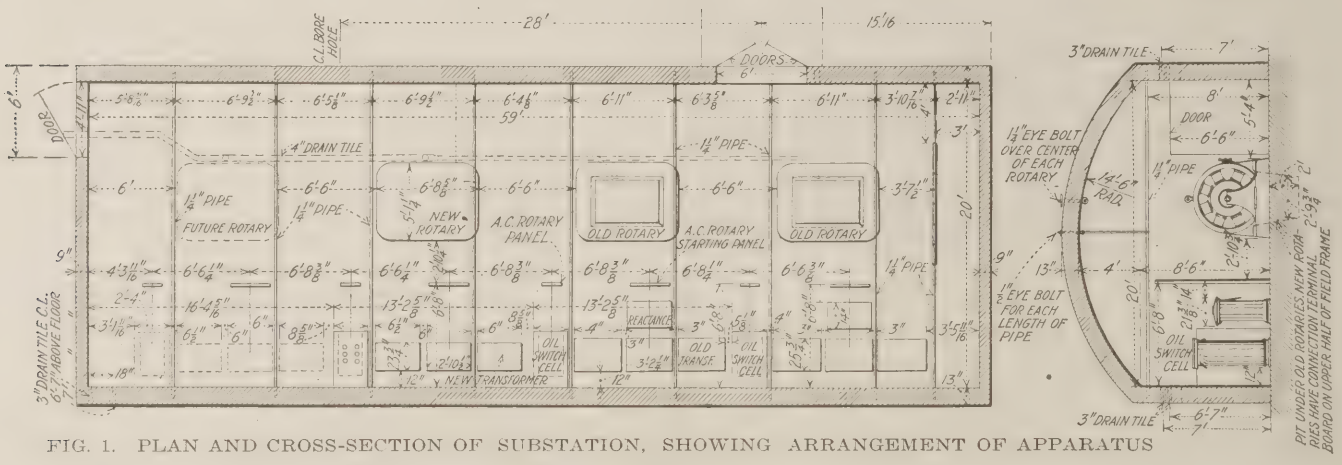

FIG. 1. PLAN AND CROSS-SECTION OF SUBSTATION, SHOWING ARRANGEMENT OF APPARATUS

The particular mine where the substation under discussion is installed is located about four miles from this central generating plant, and power was originally transmitted to it at a pressure of 6600 volts. In the initial installation and development a substation consisting of two 150-kw., 275-volt, direct-current synchronous converters, with necessary transformers, switchboard and accessories, were installed in a brick building located about 200 ft. from the pit mouth.

This first substation was installed about 1907 and served the needs admirably for several years, but finally development in the mine had progressed so far that the main workings and much of the electric locomotive haulage were more than a mile away from the outside. Additional copper feeder had been installed from the substation, from time to time, until the point had been reached where the bettering of inside voltage conditions was slight in proportion to the expense for the copper required, and the load on the substation and transmission line had gradually increased to such a value that it was necessary to provide additional capacity in both.

After carefully considering the problem, it was decided to move the substation to the inside of the mine, to a location about a mile from the pit mouth, thus placing it centrally with respect to the area to be supplied.

In order to get additional carrying capacity in the transmission line, it was decided to raise the transmission voltage from 6600 to 11,430. This was easily accomplished by merely reconnecting the power transformers at the generating station from delta to grounded Y on the high-tension winding. Of course, all the transformers receiving power from this line had also to be reconnected on the high-tension side from delta to grounded Y.

To provide the additional substation capacity, and also to prevent shutting down the mining operations while the substation equipment outside was being dismantled, moved inside of the mine and reërected, a new 150-kw. synchronous converter equipment, complete with requisite transformers and switchboard, was purchased. The transmission line was extended overland about a mile from its former terminus, to a point directly above the new location for the substation inside of the mine, and a borehole drilled down into the mine, piercing the substation room.

By shooting out the rock, sufficient space was provided in which to construct the room for the substation equipment. This substation room is 20 ft. wide, 59 ft. long, and has a brick arched roof 13 in. thick on a radius of 14½ ft., giving a height of 8½ ft. at the walls and 12½ ft. at the center. The floor is of concrete, and the walls are of brick 13 in. thick. The walls and roof are thoroughly treated with a waterproofing compound. Sheet-steel doors are used at the entrances to the room.

The borehole is cased throughout its entire length with 5-in. iron casing, cemented in. This casing is extended above the ground level about five or six feet. This prevents flooding the borehole from surface water and places the cable clamp and cable end bells, or potheads,

high enough above the ground to prevent accidental damage. Suitable knife-blade disconnecting switches are provided on the transmission line at the borehole, and there is also installed an electrolytic lightning arrester. Power is taken from the overhead transmission line down to the substation at 11,430 volts, through a No. 2 American wire gage, three-conductor, varnished cambric, insulated, lead-cased, wire-armored, jute-and-asphalt-finished cable suspended in the borehole casing. This is approximately 275 ft. deep, and the whole weight of the cable is supported by the wire armor. This is fastened by a clamp designed for the purpose resting on the top of the borehole casing. End bells, or potheads, of the disconnecting type are used on each end of the cable.

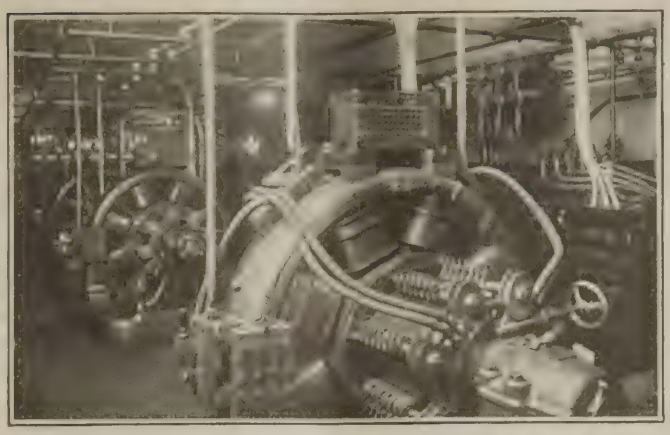

FIG. 2. INTERIOR VIEW OF SUBSTATION SHOWING PIPE CABLE SUPPORTS

The cable is taken into the substation room through the brick side wall, and connects to the high-tension bus which extends the length of the room, being carried on pipe framework, from which it is supported by petticoat-type porcelain insulators mounted on iron pins. The plan view of the room and the layout of the apparatus accompanying this article (see Fig. 1) will give a clear idea of the relative location of the different parts of the equipment.

The synchronous converters are six-phase, compound-wound, 900-r.p.m. machines, and for each converter three single-phase, 60-cycle, oil-insulated, self-cooled transformers connected in grounded Y three-phase on the high tension, and six-phase diametrical on the low tension, reduce the voltage from 11,430, at which the power is received, to 186, at which it is applied to the collector rings of the converter. With each set of three transformers there is used a separate external three-phase, oil-immersed reactance, for compounding the direct-current voltage of the converter, maintaining practically a flat compound of 275 volts from no load to full load.

The high-voltage oil circuit breakers have each pole in a separate oil tank, and are inclosed in brick cells with slate tops. They are provided with knife-blade disconnecting switches in the leads connecting them to the high-tension bus.

The direct-current panels are all grouped together at one end of the room, while the alternating-current rotary starting panel and the alternating-current rotary panel for each machine are mounted together and located conveniently to the machine which they control.

It will be seen from the illustrations (Figs. 2, 3 and 4) that all the wiring is carried overhead on a pipe framework, to which suitable porcelain insulators and fittings are attached. The main cross pipes of this framework run from one side wall to the other and are supported at a central point by a hanger from the arched roof. The overhead wiring is more accessible than that which

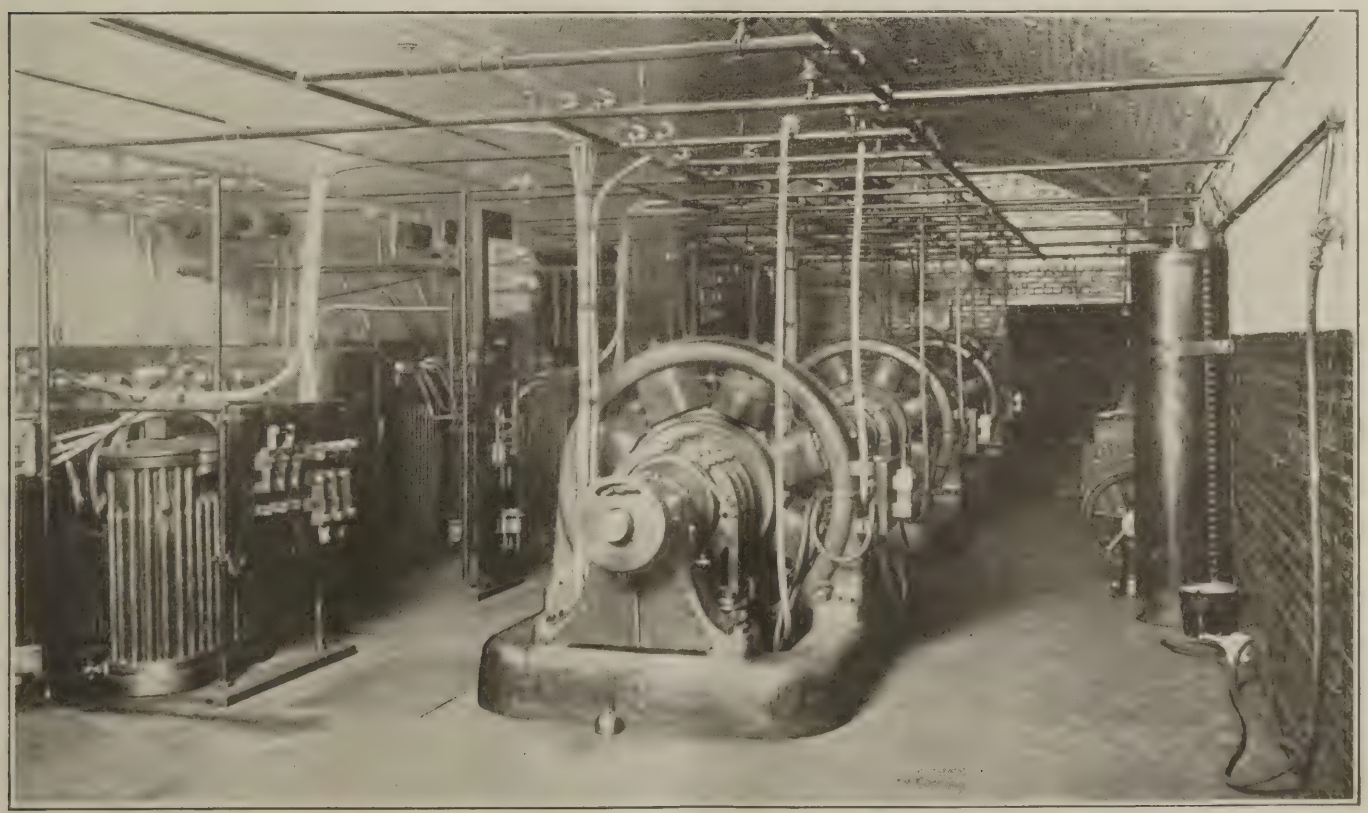

FIG. 3. VIEW IN SUBSTATION, SHOWING ROTARIES AND VERTICAL AIR RECEIVER

is carried in conduits in the floor, and it was thought less likely to give troube. Furthermore, it will not be submerged by water in the room, as that in conduit might be. The new machine was arranged specially with the terminal blocks for the leads on top of the field frame, thus making the usual pit under the machine unnecessary, and at the same time rendering it more adapted to the overhead scheme of wiring.

A small motor-driven air compressor of about 6½ cu.ft. capacity, with an air receiver, pressure gage, pop safety valve, air piping and rubber air hose, is installed for the purpose of furnishing a bountiful supply of compressed air, to be used in thoroughly blowing out all the dirt, carbon and copper dust from the machines.

All the cables are insulated with varnished cambric. A large eye bolt is set in the roof over the center of each machine for the attachment of a chain block when removing the armature, or doing other work of like nature.

In making the change from the outdoor to the inside location, the newly purchased machine and its equipment were first installed in the inside substation and put into operation, running in parallel with one of the machines in the outside substation, while the other machine and its equipment were dismantled, moved inside, reërected, and placed in operation. Then these two machines in the inside substation were operated in parallel, while the remaining old machine outside was taken down, moved inside and set up there. The whole change was made without interruption to the power supply to the mine.

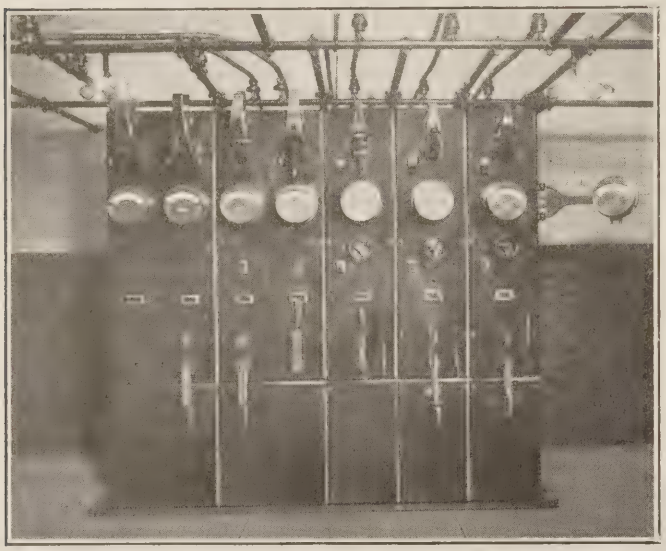

FIG. 4. SWITCHBOARD AT END OF SUBSTATION

The inside substation now contains three machines, and there is space for a fourth. This, it is expected, will be installed some time in the future, when load conditions require it.

The inside substation has been in constant daily operation since December, 1911, or somewhat over 6½ years now. The marked improvement in the operation of all classes of electric machines inside since this station has been operating has resulted in considerably fewer burnouts from low voltage, and consequently a large decrease in the cost of upkeep and more output from mining machines, pumping units and locomotives. There have also been enjoyed all the many other benefits which these features bestow, as well as those which result from a power supply with normal voltage well maintained at all times. In all respects the substation's service, operating benefits and reliability have been most satisfactory during this period of years.

In passing, it may be interesting to call particular attention to the fact that the two old machines have been in continuous service about 11 years, and that all three units are perfectly standard commercial machines, having had no special treatment to make them more moisture proof than ordinary units. The substation room is well ventilated by the air from the mine fan, is dry at all times, and no temperatures above the ordinary normal have been experienced.

Legal Department

CONDUCT OF BUSINESS BY ADMINISTRATOR—The administrator of the estate of a deceased coal merchant has no power to continue the business as representative of the estate. (Maryland Court of Appeals, Willinger vs. German Bank of Baltimore City, 103 Atlantic Reporter, 433.)

LESSEE'S RIGHT TO USE MINE PASSAGEWAYS IN REMOVING COAL FROM ADJOINING LANDS—Under a general warranty deed to underlying coal, with the right of ingress and egress to and from the land proper for the purpose of mining and removing the coal, without express provisions as to the time for removal nor as to use of the passageways in removing other coal, the grantee became vested with ownership of the coal in fee, terminable only by exhaustion of the coal or abandonment of the grantee's rights. He is also entitled to utilize the space made by removing coal for the purpose of removing coal owned by him under adjacent lands. And while a tract that is in open workable condition is being mined, the fact that there may be a temporary suspension of operations therein will not deprive the mine owner of the right to use the driveways for transportation of other coal, where he is acting in good faith and mining in the customary manner. Nor is coal in the ribs of a mine forfeited because left for a time to support the surface, the owner of the land having waived the right of surface support. (Pennsylvania Supreme Court, Westerman vs. Pennsylvania Salt Manufacturing Co., 103 Atlantic Reporter, 539.)

APPORTIONING DELIVERIES UNDER CONTRACT FOR YEAR'S FUEL REQUIREMENTS—Plaintiff contracted to deliver defendant's entire requirement of coke for one year, estimated at 40,000 tons, for shipment in approximately equal monthly installments. In certain months deliveries fell materially below the average of 3333⅓ tons called for by the contract, and defendants demanded deliveries in excess of that average quantity. Plaintiff sued for the price of coal delivered but not paid for, and defendants counterclaimed for damages for failure on plaintiff's part to fill orders in excess of 3333⅓ tons in each of certain months. Held, that defendants were entitled to credit for losses sustained through plaintiff's failure to make deliveries up to the full average quantity of 3333⅓ tons for each month, but that there was no breach of contract in plaintiff's failure to make monthly deliveries in excess of that quantity. "Taking into consideration that each month's delivery was to be treated and considered as a separate and independent contract, we cannot agree with the construction placed upon the contract by the defendants that the plaintiff was required to anticipate and provide quantities greatly in excess of the approximate stipulated amount required to be delivered each month under the terms of the contract. In effect, the plaintiff would unexpectedly be called upon in any given month to furnish any quantity of coke only limited by the full running capacity of the plant of the consumer." (Pennsylvania Supreme Court, Poland Coal Co. vs. Rogers, 103 Atlantic Reporter, 559.)

Advantages of Storage-Battery Locomotives*

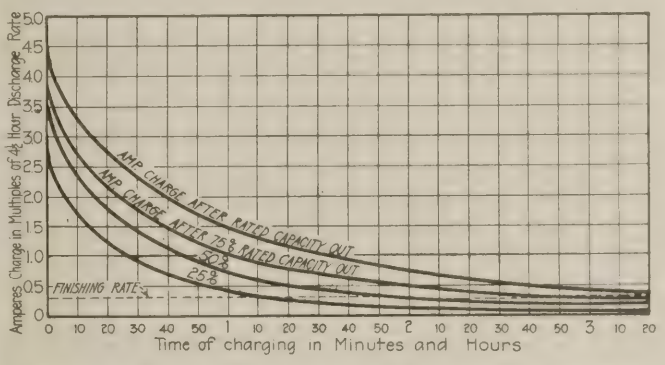
By C. W. CHAPPELLE
Manager St. Louis office of the Ironton Engine Co.

THE use of the storage-battery locomotive in mines for gathering coal is a comparatively new application of one of the oldest pieces of electrical apparatus we have, as storage batteries, in one form or another, have been in use in this country for nearly thirty years; and while the storage-battery gathering locomotive has only been in general use for about four years, it has proved to be eminently satisfactory when used under the proper operating conditions.

Until the introduction of this machine there were about four general methods of gathering coal; namely, by mules, by cable-reel locomotives, by electric crabs and by straight trolley locomotives. As the purpose of this paper is to point out some of the advantages of storage-battery locomotives, it would probably be best to discuss briefly the other methods in the order mentioned.

The actual cost of mule haulage will, of course, vary with localities and mine conditions, but it has increased greatly during the past two years. In a great many mines where the coal is low it is usually necessary to cut out additional top or bottom, and sometimes both, to obtain the head room required for the mules. Again, the amount of coal that can be hauled by mules in low coal as against that in high coal is naturally less, owing to the difference in the size of the mules which can be used. In figuring upon the maintenance of mules in coal-mining work the main items of expense are first cost, feed and shoeing, veterinary, barn attendance and harness.

Importance of Housing, Drainage and Ventilation



In addition to the items noted the question of proper housing, drainage and ventilation are important factors, as well as the transportation of food and refuse if the mules are kept underground. Stables for mules should be kept clean and well lighted, as good care means simply good insurance. A mule may last at this work anywhere from five to ten years, but again he may be killed by accident at any time, and the amount of work which he can do will always vary with his physical condition.

The cable-reel locomotive is an adaptation of the trolley locomotive for gathering purposes, by means of a more or less complicated motor-driven cable reel mounted upon it. In order to obtain the best results from a machine of this type the tracks in the rooms should be bonded. On account of the fact that this cable-reel mechanism is complicated and that the cable is always subject to excessive wear, accident and abuse, the upkeep of this type of machine is always high, although its first cost may be somewhat lower than that of a storage-battery machine; but on account of these points it cannot gather as much coal in a given amount of time.

The electric crab is a device built on the nature of an electric winch and is used for the purpose of pulling cars out of a room by means of a flexible rope or cable; it is generally used where the grades are so heavy that they can not be negotiated by either a locomotive or a mule.

The straight trolley locomotive is also used for gathering, but the method calls for installation of trolley wires and track bonding in the rooms. Also, on account of the necessity of constantly handling the trolley pole and because the trolley voltage in the rooms is usually low, due to excessive copper loss, it is much slower than the storage-battery locomotive.

The storage-battery locomotive realizes more of the ideal conditions in connection with the gathering of coal than any other machine which has been produced up to date. It eliminates the cost, installation, upkeep and damage of overhead wiring, as well as the expense of track bonding. It allows of increased speed in gathering, as well as the elimination of handling a trolley pole or cable. It combines the speed, power and dependability of the locomotive with the simplicity of mule haulage and means greatly increased production over all previous methods.

CHARGE CHARACTERISTICS OF STORAGE BATTERY

The curves show what may be accomplished in the way of charging at high rates of current at the beginning of the charge and tapering the charging rate off as the charge progresses. These results were obtained by charging a battery from a constant potential source, the voltage of which was equal to the number of cells in the battery multiplied by 2.3. Under this method, with the battery discharged when put on the circuit, one half of a complete charge would be put into the battery in one hour. Also, as the charge progresses, the current automatically tapers off so that the cells never gas or heat injuriously

The field or range of action of the storage-battery locomotive has not as yet been clearly decided or limited. It seemed at first as if it would be limited merely to gathering work, but in many instances it has been used to advantage in main-line haulage. This is true particularly in new propositions which are just being started and where the distances to be traveled are not too great, and also in situations where the grade is favorable to the loads to be hauled.

I do not believe, however, that the storage-battery locomotive will supersede the trolley machine for main haulage work in general, but rather that an intelligent combination of the two types will nearest approach the ideal condition; this condition, of course, means the greatest number of tons of coal transported during a working day for the least amount of money per ton.

*Paper read before the Peoria meeting of the Illinois Mining Institute, May 24, 1918.

The storage-battery locomotive does mean, however, more tons of coal gathered with the use of less men, less power, less upkeep and less all around trouble than by any other mechanical means.

There are two distinct types of storage-battery locomotives in general use. One is the straight storage machine, in which the size and capacity of the storage battery is relied upon to do a full day's work, and the other is the combination type in which the storage battery is oftentimes comparatively small and is simply used as an auxiliary source of power in a trolley machine; the motors in the machine are operated in series when working from the trolley and in parallel when working from the battery, the battery receiving some charge from the trolley through a resistance during the former period.

Naturally the heart of a storage-battery locomotive is the battery, and contrary to the general belief a storage battery is not a thing of mystery, neither is it a complicated piece of apparatus requiring highly skilled men to look after it. It is one of the oldest and simplest pieces of electrical apparatus that the electrical engineer has to deal with, and can be cared for by anyone who is willing to obey simple instructions. Like the mule, however, it needs food and drink, and it requires it regularly. The food is electricity applied in the form of amperes for a certain amount of time, and the drink is pure water; and unless the water is known to be pure it should be distilled to make sure. Storage batteries should not be overheated while being charged; such overheating is usually caused by charging at a higher current rate for a longer period of time than the instructions give.

The batteries in these locomotives are usually put in specially designed compartments, either in or on the locomotive frame; the cells are assembled in groups in extra-heavy wooden trays, and these trays are usually insulated, by some form of porcelain insulator, from the locomotive frame. The individual battery cells are so assembled in the trays that the flat of the plate is in the direction of motion of the locomotive, thus producing a "dashpot" effect in the jars and absorbing all hammer-blow effects against them.

Troubles Experienced in the Early Days of Locomotive Construction

In the early days of locomotive construction considerable trouble was experienced with the lead type of storage battery due to jar breakage. This has been practically eliminated by the use of a so-called "guaranteed compound" jar, which is really an extra-heavy walled jar with a lot of rubber in it. In the Edison type of battery the jar is of metal and jar breakage is therefore eliminated. Originally a spring suspension scheme for the batteries was tried to some extent, but as it was never very practical it did not come into extensive use. At present the general practice is to assemble the trays in the battery compartments as snugly as possible, leaving just enough clearance so that a tray may be lifted out when required. Practical experience has demonstrated that rigid battery compartments with trays assembled in this manner are best.

There are two distinct types of storage batteries used in this class of work; one being the lead-sulphuric acid type and the other the iron-nickel-alkaline type, better known as the "Edison."

The lead battery used for this purpose is what is known as the pasted-plate type, with the exception of the "ironclad exide," in which the active material, as the lead oxide is called, is inclosed in slotted hard rubber tubes to keep it from shedding. The solution, or electrolyte as it is called, in the lead battery is a mixture of sulphuric acid and water having a specific gravity of approximately 1280 deg. The working voltage range of a lead cell on discharge is from 2 to 1¾ volts. The life of the lead type of storage battery used in these machines will be approximately 18 months to 2½ years, depending upon their construction and the kind of care they receive.

Characteristics of the Alkaline Type of Battery

The alkaline type of battery, better known as the Edison battery, is composed of positive plates containing nickel hydrate in perforated steel tubes and negative plates containing iron oxide in rectangular tubes or pockets, the containers in both cases being nickel plated. This element or group of positive and negative plates is contained in a nickel-plated steel jar, and the solution or electrolyte is a mixture of caustic soda or potash having a specific gravity of about 1250 degrees.

The working voltage range of an Edison cell is from 1.4 volts to 1 volt, approximately. The life of this type of battery is estimated at five years. On account of the difference in the working voltage of the two types of battery it is necessary to use a greater number of cells of the Edison battery than the lead type.

The batteries on these locomotives are usually charged either through a suitable resistance direct from the 250-volt trolley circuit in the mine or they are charged by means of a separate motor-generator charging set, in which case the voltage of the generator can be properly proportioned to the battery. The motor-generator method of charging is by far the best for the battery, and is also the most efficient in regard to current consumption. It is, however, considerably higher in the matter of first cost.

I would state that I have tried in this paper to outline the storage-battery locomotive and its application in a general way only. I have not tried to go into comparisons of cost as against mule haulage, but for general purposes it is safe to assume that a four- to five-ton storage-battery locomotive will replace from three to four mules. Each installation is a problem by itself, and this problem readily can be solved by taking the following points into consideration: The number of cars to be hauled per day; the number of cars to be hauled per trip; weight of the empty cars; weight of the loaded cars; greatest distance locomotive will have to travel per trip; the grades the locomotive will have to encounter in making one trip or cycle, both with and against the load; general character of the track and mine cars. In this connection the round trip should be divided into parts having different characteristics, such as different weight of train and different grades to be encountered.

With the foregoing information a person will be able to go to the various builders of the machines and obtain a clear and concise idea as to what can be expected in the way of results.

Discussion on Mr. Chappelle's Paper

FOLLOWING the reading of the foregoing paper there was a most interesting discussion on the merits of the storage-battery locomotive as applied to the gathering of coal in mines. The special field of this type of motor was enlarged upon and information was desired as to the care which should be given this machine, both in charging and in operation. Possible battery troubles were also discussed. The haulage of powder by electric locomotives brought out some good points, and the application of the storage-battery type to this service was commented upon. Altogether it was an unusually good discussion and the principal points made by each of the speakers participating in the discussion are noted in the following pages.

IT was stated by C. W. Chappelle that it costs approximately one-half as much to gather coal by storage-battery locomotives as it does with mules; that the storage-battery locomotive has come into active use in coal mines during the last four years, and is therefore comparatively new as regards coal mining. This type of locomotive is not a universal panacea for all haulage problems, and it is not expected to supersede the trolley locomotive; but an intelligent combination of the two should produce the best results. In many instances storage-battery locomotives are installed where trolley motors should have been put in. An intelligent investigation should be made in each case to see whether the battery locomotive is suited to the work.

Continuing, Mr. Chappelle noted that a storage battery may be charged at a high current rate at the start, provided the current is tapered off, so as to prevent gassing and overheating of the battery. As to storage troubles, in the first stages of battery-locomotive design much difficulty was experienced with jar breakage, but this was largely eliminated by the use of heavier trays and jars, and by installing the cells so that the flat of the plate is in the direction of travel (the length of the plate across the track) of the locomotive, thus providing a dashpot effect in the jar.

In regard to progress made, it was stated that in the earlier types of battery locomotives the speed was rather slow, being around 2½ miles an hour. Modern machines operate at from four to six miles an hour when loaded and from six to ten miles an hour running light. A good point was made by Mr. Chappelle who suggested that the Institute appoint a committee to collect and tabulate data on the actual cost of the various methods of hauling and gathering coal, whereby an average cost could be arrived at. Up to the present time not many mines know what it is costing them, and no two mines have exactly parallel operating conditions. The answer to the ultimate problem in all engineering propositions usually resolves itself into dollars and cents.

A number of representatives of storage-battery companies were present and responded to requests for information. At this point, Taliaferro Milton, Chicago district engineer of the Electric Storage Battery Co., with general office and works at Philadelphia, Penn., remarked that the storage-battery locomotive has its own special application in coal mines and that great care should be taken to see that it was properly applied. In his opinion it would never entirely replace the trolley locomotive—both types have their own fields of application. The storage locomotive in a few instances has been misapplied, and in such cases its failure has not been due to any inherent defect of the locomotive or batteries, but nevertheless such failures have given this type a "black eye" at times.

Further, great care should be taken in analyzing the haulage conditions before the locomotives are purchased, to determine the proper battery capacity. A large percentage of troubles with storage-battery locomotives has been due in the past to the fact that not sufficient battery capacity was provided for in the initial installation and no provision made for substituting a larger battery. From the original survey it is a simple engineering problem to calculate the required capacity in kilowatt-hours necessary to do the work in hand. This capacity having been determined, T. Milton would recommend that a storage battery having capacity considerably in excess of the calculated quantity be installed. In fact, he would recommend that the calculated requirements in kilowatt-hours be used as a guide to determine the minimum battery which should be used, and that the actual battery adopted should be the largest one which can be installed on the locomotive within the limits of the available space and weight requirements, providing this larger battery does not exceed double the calculated capacity requirements.

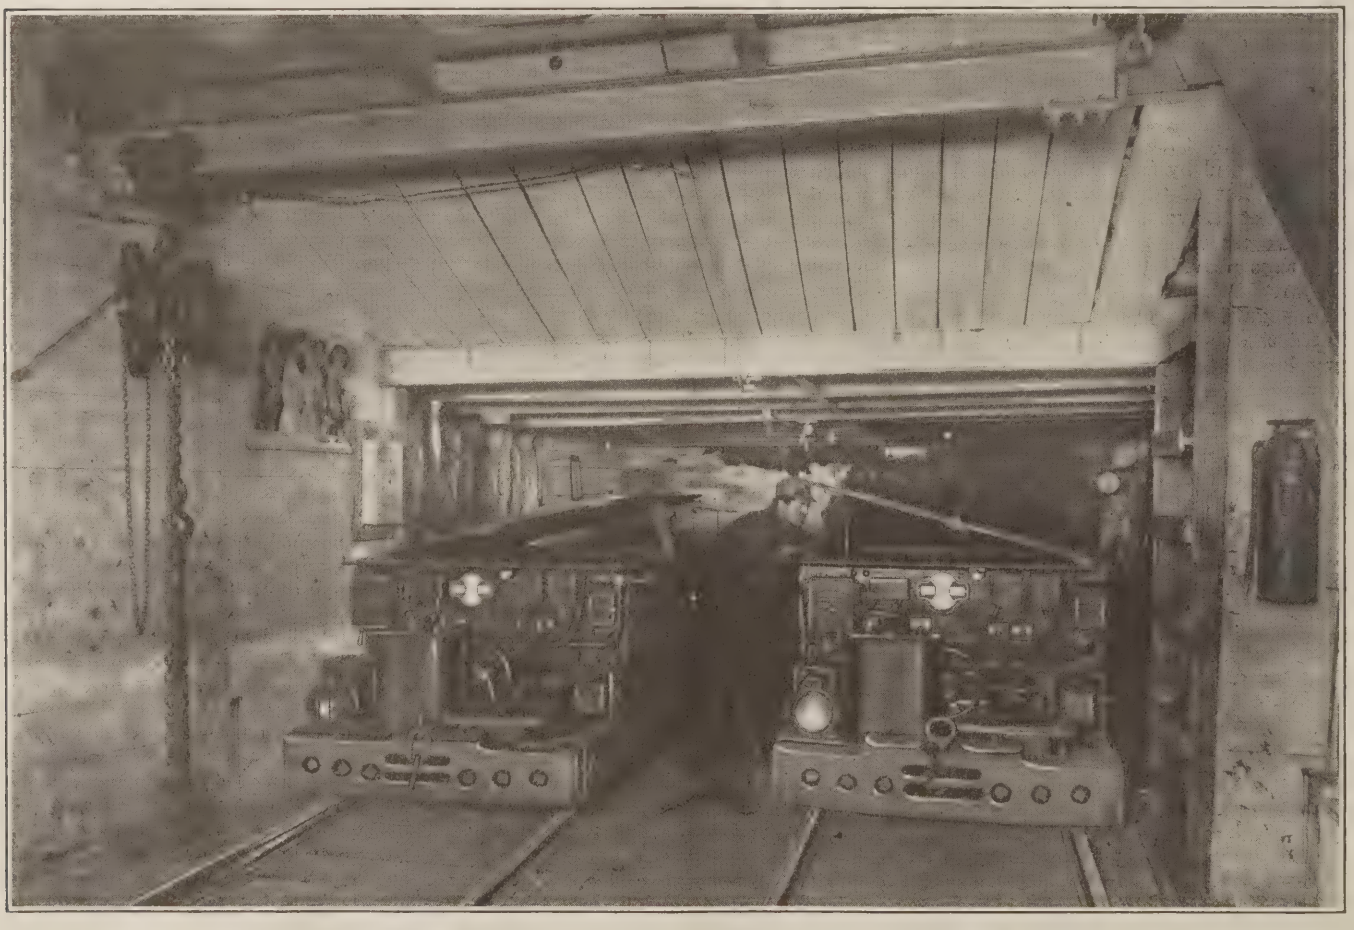
Continuing, he stated that the locomotive manufacturers must protect themselves in selling battery locomotives by specifying what the locomotive will do under definite, specific conditions of tonnage, length of haul, grades, working hours and other duty conditions. The locomotive may be sold under these definite specifications and live up to them on trial runs. Later on the conditions in the mine may be entirely changed and the work required of the locomotive will be so increased that it may be found that the battery on the locomotive is not of sufficient capacity to do a day's work. While this is no fault of the locomotive or battery, and while the manufacturer is protected by the working specifications, yet the operators are dissatisfied because the locomotives cannot meet the excessive requirements. If, therefore, a liberal factor of safety is used in determining the proper battery capacity, this condition will probably never arise. The money expended in this additional capacity is not wasted—it is a real investment. Even if this excess capacity is never taken out of the battery during any one day, the battery, because it is not worked up to its full capacity, will have an increased life; therefore, while the original investment is increased on account of the excess battery capacity, the maintenance is reduced. The excess investment is therefore returned to the purchaser in longer life of the battery. Simultaneously, the excess capacity acts as an extra insurance and has a real value to the operator.

Mr. Milton lays particular stress on the care and operation of the batteries on the locomotives, saying that there is no such thing as a "foolproof" battery—batteries require systematic attention. The instructions given by the battery manufacturers are simple and any mine employee who has common sense and who can be relied upon to obey orders and follow instructions can, in a short time, be converted into a good battery operator. The actual time spent in the care of the battery is little if the attention be systematic and in accordance with the instructions.

The point was brought up that the determining factor in selecting storage-battery locomotives for operation in coal mines is cost per ton of coal handled. While this question is largely an economic one, and while any one would install battery locomotives if it was proved that the cost per ton of coal handled would be reduced by the use of such locomotives, yet there are cases where the storage locomotives will be used even though the cost per ton of coal handled is increased by the use of this type. There are cases where it is necessary to use locomotives in order to get the required tonnage. The Electric Storage Battery Co. maintains a staff of competent engineers who visit the mines from time to time to inspect the batteries and to coach the operators in the proper handling of them. If the operators will take advantage of the services thus offered, the benefits to the manufacturers and operators will be mutual.

Mr. Bowers, of the Edison Storage Battery Co., of Orange, N. J., spoke of the disappointment expressed in the work accomplished by the battery loco-

motive in six months or a year. The work might be increased from 50 to 100 per cent. over that for which the locomotive was bought, and then the motor might be condemned because it would not respond. It was advised that in the original installation the demand be figured out and then the capacity of the locomotive be increased from 25 to 50 per cent. Also in the care of a locomotive—the services of an expert are not required—any man of intelligence who will follow a manufacturer's instructions will do. The storage-battery type is becoming so well known that a special operator is not necessary. In the early days it was necessary, but not now.



In replying to inquiries as to trouble encountered in the operation of storage-battery locomotives, T. Milton stated that the chief trouble was due to too small battery capacity, as previously noted. Too much emphasis could not be attached to this feature of locomotive design; also a battery should receive systematic attention and care. The regular instruction book issued by the Electric Storage Battery Co. gives some good ideas in this connection, but the main points, however, are brought out on the metal plate the company attaches to the battery box on the outside of the locomotive. The points brought out on this nameplate are the fundamentally important ones to which special attention should be paid.

Prominent among all instructions are suggestions about charging batteries. The motor-generator set is better suited for charging storage batteries than is the trolley current, for the following reasons:

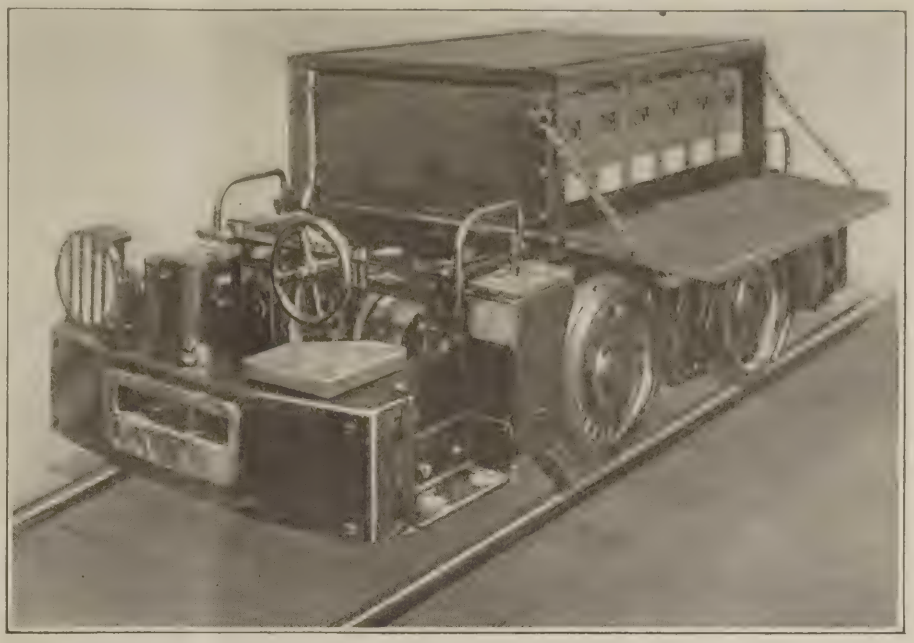
The battery usually consists of 48 cells, and to completely charge this battery requires from 110 to 125 volts. The trolley voltage is usually 250 volts, so that in order to charge the battery direct from the trolley it is necessary to put in a rheostat to reduce the voltage at the battery terminals to 125 volts. It is thus seen that if the full 250 volts are maintained on the trolley there will be as much energy wasted in the charging rheostat as is stored in the battery. Aside from the wastefulness of this method of charging direct from the trolley, the trolley voltage varies considerably so that it is difficult to determine beforehand just how much resistance is required in the rheostat to produce the proper current for charging the battery in a specified time. By the use of a motor-generator set a practically constant voltage can be maintained at the battery terminals with no loss, except the regular losses in the motor-generator set. Moreover, by obtaining any desired voltage the battery can be charged properly in accordance with the battery characteristics and thus insure better operation from the battery.

In reply to an inquiry as to the protection afforded a storage-battery motor against injury from overload, C. W. Chappelle stated that most locomotives have fuse or circuit-breaker equipment, and the motor is protected by either slipping the wheels, the circuit breaker opening or the fuse blowing. The slipping of wheels on a storage-battery locomotive will not hurt anything, and it acts as a safety valve against overloading the motor. As to the fuse, the only danger is that sometimes too heavy a copper wire is used as a fuse and when it does not melt at the proper time then a burnout is caused. The storage battery is a reservoir of energy and has a great capacity; this large capacity is used, not to handle heavy overloads on the locomotive, but to operate it over a considerable period of time at normal capacity. However, a standard five-ton Ironton locomotive having a rated drawbar pull of 2500 lb. has actually given 4000 lb. on a good clean rail. Motors used in storage-battery locomotives are not rated in horsepower but are based on a temperature rise of 75 deg. C. for a period of one hour. A 10-hp. series motor may be safely operated at 30 to 35 hp. for short periods of time or momentarily.

The question was asked what troubles occur with the battery itself. Mr. Chappelle replied that trouble is sometimes caused by a battery being improperly charged. The success of a battery locomotive depends largely upon the proper installation and charging of the battery; it is better to purchase

CHARGING TWO FIVE-TON STORAGE-BATTERY LOCOMOTIVES IN A MINE

The operator is shown testing the specific gravity of the solution in the storage-battery cells to determine the state of charge. The specific gravity (that is the density) of the solution in a lead storage battery varies with the state of charge and gives a direct indication of the condition of the battery



the charging equipment for the locomotive from the makers and thus get a complete unit designed to work together and insure against divided responsibility. Locomotive manufacturers furnish complete motor-generator sets and automatic switchboard equipment to properly charge batteries.

Mr. Milton here brought out some interesting points. In comparing the trolley and storage locomotives, he stated that in the former type the limit to power is the station; but this is not true of the storage battery. In this connection, power and energy should not be confused. The faster the current is used the quicker will the battery be exhausted; the kilowatt-hours determine the length of activity of a battery, and the rate at which the energy is used up is indicated by the pointer on the meter.

Continuing along this line of thought, W. G. Ferguson, of the power and mining department of the General Electric Co., of Schenectady, N. Y., stated that it has been some five years since the storage-battery locomotive was first installed on a practical basis in coal mines and that Mr. Chappelle no doubt recalled having witnessed the first trial locomotive which was placed in a mine near Cambridge, Ohio, and which was tried out for several weeks. This installation occurred shortly before the strike came on in Ohio and for certain reasons the locomotive did not prove satisfactory to the mine management. It was practically impossible to keep the locomotive on the rails due to the fact that it was being operated over mule tracks, and instead of hauling coal the locomotive would be on the ground for three or four hours each day.

The locomotive was taken out of this mine and resold to a mine in Indiana and has been in continuous use for several years, giving the owner remarkably satisfactory service. This bit of history was given in order to illustrate the main points to be brought out to the effect that battery locomotives cannot be applied haphazardly to coal mines, as conditions vary so greatly that failure will result in many cases unless a thorough study has been made of the situation. When applying storage-battery locomotives to coal mines, especially for gathering work, it is essential to know a great many things about the mine which are otherwise not necessary when applying the trolley type of locomotive. It has become the practice to apply trolley locomotives solely on a basis of weight and dimensions, as the amount of power used by the trolley locomotive is practically unlimited in quantity since it is derived from the trolley wire. The storage-battery locomotive is at a disadvantage in this respect because it must carry the power with it.

One must know exactly how the locomotives will distribute and collect cars, whether cars will be placed at and taken from the "face" or whether they will be delivered at the room necks. Furthermore, it is essential to know the weight of loaded and empty cars, approximate car output per day per locomotive, grade conditions, depth of rooms, side and height clearances, length of entry (whether this is single or double entry) and finally the location of the parting with respect to the working rooms. It is, of course, difficult at times for a prospective operator to accurately state all of these details, but he can as a rule give a very close estimate of how the operation of the mine will be handled. When all of these conditions are known, it is possible to calculate the amount of battery power necessary for a day's work and then the weight of battery can be proportioned to the weight of the locomotive chassis. It is obviously impractical to design a locomotive with an overbundance of battery capacity and at the same time obtain a locomotive chassis of sufficient weight and strength to carry this battery without obtaining a locomotive as a whole far out of mechanical proportions and very much heavier than necessary for the work. It is sometimes found to be the case that these gathering locomotives will be handled in much the same way as when mules are used. That is, if it has been the past practice to haul two or three cars with mules, the new user of battery gathering locomotives will doubtless continue to haul two or three cars with the battery locomotive, thus resulting in very inefficient haulage and requiring far more battery capacity than would otherwise be necessary if larger trips better proportioned to the weight of the locomotive are used.

FOUR-TON ELECTRIC MINE LOCOMOTIVE EQUIPPED WITH 48 CELLS

Continuing, Mr. Ferguson said that the locomotive will handle from three to five times as many cars as a mule, and when doing so will be working at the normal working load for which the locomotive was designed; thus it will use a less amount of battery power than if it is compelled to make frequent trips over a long track with a very light load. It should be realized that the weight of the locomotive is a large percentage of the total weight of the trip, and consequently a good deal of battery power is used up in operating the locomotive itself. A locomotive should not be loaded up to the slipping point of the wheels, as this condition causes the storage battery to deliver an abnormal rate of current which tends to reduce the battery capacity and the speed of the locomotive.

When the operation requires the handling of small trips and the cars are distributed over a wide area, it is better to plan on using two small locomotives rather than one large one, as the total amount of battery capacity needed for covering the extended mileage is so large and heavy that the locomotive itself will be inefficient and will use the battery power to a very decided disadvantage. In fact it is oftentimes the case that two locomotives of a well proportioned weight and battery capacity can obtain a given car output with less total battery capacity than would a large, heavy locomotive which carries the battery around all day long, hence uses power for moving this excess amount of battery. The above remarks are, of course, more or less of a general nature but they are capable of being proved by concrete examples. The main point which Mr. Ferguson endeavored to make was that one must know the amount of kilowatt-hours used by a given locomotive and make the most economical use of it.

A good deal of careful consideration should be given to the selection of the charging apparatus, as the life and safety of the storage battery depends to a great extent upon how a battery is charged and the safeguards taken to prevent a heavy reversal of current. Standard lines of charging panels are available from several large manufacturers who have made a special study of battery requirements and will furnish equipment best suited to the type of battery in use. The most important feature of the charging panel is the re-

verse current circuit breaker, which will open the main charging circuit whenever the source of power is interrupted either by opening of a station breaker or by short circuit between the generator and the storage battery. If short circuit occurs and no protection is provided, the battery may reverse the current and attempt to feed other apparatus such as pumps, fans and other machines that may be operating on the lines. If an 85-volt battery is being charged direct from a 250-volt trolley circuit, there is usually enough series resistance in the charging circuit to limit the amount of reverse current to a safe discharge value. However, if the circuit is not interrupted, the battery locomotive would be discharged in the morning instead of being charged, and consequently a day's loss would be the result. It is quite obvious, therefore, Mr. Ferguson noted, that one can afford to spend a few hundred dollars for the protection of the expensive storage battery.

When storage batteries are charged from a 250-volt circuit, it is necessary to use a regulating rheostat in the circuit to reduce the voltage of the trolley to that required at the terminals of the battery. Consequently, there is considerable loss in the rheostat itself. Take, for instance, a 48-cell lead battery. When it is charged by the so-called constant current method it requires 125-volt maximum at the end of the charge, and if a 250-volt trolley circuit is used, the loss in the rheostat will equal the amount of power put into the battery. An 80-cell Edison battery charged in the same manner will require 150 to 155 volts resulting in the loss of about 100 volts in the rheostat. If but one or two storage-battery locomotives are used in the mine, this loss of power in rheostats is not important, but when 10 or 12 locomotives are used the kilowatt-hours in the rheostat will be considerable and it is then essential to select a motor-generator set having a generator voltage equal to that required for the charging of the battery; thus the charging power may be used most economically.

In conclusion Mr. Ferguson stated that the storage-battery locomotive should be operated so that the loads will not be too large or too small for the rating of the locomotive, and a good deal of judgment should be exercised by the operator. Brakes should be used with discretion and this bad habit common to operators of trolley locomotives should be overcome. The storage battery should be watered regularly and charged in the manner prescribed by the instructions.

James Taylor, coal investigator of Illinois, introduced the subject of powder haulage and called attention to the strict state laws in this matter. He considered that if a storage-battery locomotive conveyed powder to the face that it might ground and explode the powder. However, as to the care of this type of locomotive, he believed it was no more care than a mule. In charging the storage battery the locomotive should rest on wood rather than T-rails, to avoid escape of electricity, provided such were possible. As a case of quite questionable management Mr. Taylor cited a mine in which four motors were used for haulage. It was the custom here to change around the motormen once a month; under this system a runner learned the grade on his haul and then exchanged with a motorman from another part of the mine, and both runners commenced over again to learn their runs.

Continuing on the subject of haulage of powder, the statement was made that a storage-battery locomotive undoubtedly was safer to use in such service than a trolley locomotive would be. Mr. Chappelle was of the opinion that a number of factors enter into the reason for this: the battery is in a steel compartment usually covered with fairly tight covers, and the electrical circuit of this type of machine, while it is running, is contained within itself; that is, the circuit is a metallic one, the current traveling from the battery to the controller, through the motor and back to the battery again. He agreed that in charging a storage-battery locomotive from a 200-volt grounded trolley circuit that it should be charged on wooden rails where possible. He also cautioned that an open flame should be kept away from the battery compartment at charging time, for the reason that if the gas which is given off at charging time is ignited then cracked jars or broken covers are liable to result.

Further, about the only way that sparking could occur in a battery locomotive while it was in operation would be by wiring trouble, controller or motor trouble, a loose cell terminal or the burning off of such a cell terminal. As to the production of sparks at the time when powder is being hauled, a mule can produce sparks by its shoes striking certain rock or steel. And as far as that goes, a man pushing a powder car might smoke. It is a significant fact that prominent manufacturers of explosives are using storage-battery locomotives in their works, as they are the safest mechanical method of haulage around plants of this character. The inference was drawn that there would be slight danger in coal mines comparatively from similar use of the battery locomotive. As a precaution, an empty car might be placed between the locomotive and the powder car which would seem to eliminate any danger from stray sparks; if an insulating drawbar was used, it should still further eliminate the possibility of any leakage current getting to the car. The comment was made that currents still could be transmitted through the track from the motor to the car; also if the empty car was wet, the insulation would be weakened.

An interesting contribution to the discussion was made by A. J. Moorshead, president of the Madison Coal Corporation. He stated that the selection of the method of hauling powder was a matter of safety and economy. In a general way, he considered that an operator was foolish to use storage locomotives for distributing powder. The Madison company is putting in storage-battery locomotives, but they will not be used for hauling powder. A special powder car has been devised by Mr. Moorshead which is expected to be electricity proof. Three powder transportation boxes are being constructed of two layers of wood between which is sheet asbestos. Wooden screws are used where fasteners are needed. The powder box is mounted on a truck and each car complete will cost from $100 to $150. Before being placed in active service, these cars will be tested; after the box has been filled with powder in cans, a wire will be passed round the box a number of times and a current of electricity will be turned on.

Mr. Moorshead went on to say that 25 per cent. of his time was given to investigating safety matters. In connection with haulage he noted that while mule drivers constituted 5 per cent. of the force, accidents to them amounted to 30 per cent. Also that 30 per cent. of expenditures for accidents was for drivers. As a class they are reckless and uncontrollable. Here Mr. Moorshead related a story which was particularly well appreciated, but the writer will not attempt to repeat, as a layman should never try to encroach on the special field of a pastmaster in an art. In view of his findings in the haulage situation, he gave storage-battery gathering locomotives a trial and found that while developing best efficiency, a storage motor displaced 3½ mules and on 320 tons of coal hauled a saving of 1½c. a ton was effected. Furthermore, this mechanical haulage eliminated 60 to 70 per cent. of inside coal transportation accidents. In view of all this, the Madison Coal Corporation is equipping its plants with storage-battery locomotives and considers them a good investment.

The transportation of powder in the state coal mines was of considerable interest to the members of the Illinois Mining Institute. Accidents from explosions of powder en route from the foot of the shaft to destination brought about the enactment of laws requiring all current to be shut off from a mine at times of haulage of powder. The main switch is securely fastened so that no current passes through the inside feeder wires. Two men lock the switch down and it takes both to open it. Mr. Moorshead states that the men of his company were taught the rule of strict obedience to orders in this connection—if they failed, they were given a good stiff army order. Many times the reason for accidents was due to lack of order, discipline and obedience; the latter two on the part of the employees of a company—the former in the case of a plant which does not have the good appearance a manufacturing concern should possess. Neatness and order about a plant are assets whose value often amounts to more than dollars and cents to a company.

Outbursts of Gas in Crowsnest Field*

By JAMES ASHWORTH
Consulting Mining Engineer, Vancouver, B. C.

SYNOPSIS—*Describes certain violent gas outbursts which, with other causes, have closed down mines in the Crowsnest field. One mine gives off 15,695 cu.ft. of firedamp per ton of coal mined, the volume of the methane at atmospheric pressure being about 580 times the volume of the coal. One authority believes the coal is an unstable chemical compound and suddenly changes its condition. The presence of other hydrocarbons than methane and possibly the presence of hydrogen adds to the danger. The author advocates longwall methods for working such coal.*

IN 1914 I contributed to the Manchester Geological and Mining Society a paper entitled "Outbursts of Gas at the Morrissey Collieries." These mines were owned by the Crow's Nest Pass Coal Co., Ltd. In continuation of what was there stated I may say that after No. 1 mine was closed work was not resumed in this part of the coal field until 1907, when a new mine known as No. 7 was opened up.

This mine was lower down in the geologic section than No. 1 mine, and had an overhead cover of about 800 ft. The seam has a steep angle of dip (65 to 75 deg.) and a total thickness of 32 ft. Only about 16 ft. of the footwall portion was worked, and in the middle of that portion was a natural parting, separating the two 8-ft. portions, the bottom half of the coal being harder than the top part. The mine was ventilated by a force fan, and therefore the main haulage road became the return airway.

Gas Filled Face of Heading with Small Coal

The first serious outburst of gas in No. 7 mine occurred at the face of the main level on Jan. 27, 1909. It filled the level with small coal for a distance of 15 ft. from the face. The gas was given off in such a large volume that it extinguished a safety lamp 30 ft. outside the main entry. Yet a horse which was left inside by its driver was afterward found alive.

On Apr. 19 a second outburst occurred in the upper counter level, about 1550 ft. from the outside. It displaced 15 tons of coal dust and was accompanied by the discharge of a considerable volume of gas.

A third outburst took place May 5, in a raise in the soft coal between the main entry and the upper counter level. The raise was up about 25 ft. and 14 ft. back from the face. Two men were at work in the raise and had evidently attempted to escape, as one was found on the timber at the bottom of the raise and the other in the level below, both having been smothered by gas and dust. Only about six tons of coal dust was displaced. It may be noted that both the level and upper counter were open for several yards past the place where the raise was being driven up.

A fourth outburst occurred May 19 at the face of the main entry, soon after the miners had completed a setting of timber. A cracking sound warned them and they escaped to the outside without injury.

I visited this mine about a month after the outburst, and found that the displacement of coal had been almost entirely from the upper or softer part of the seam, and that the cavity extended upward about 25 ft. above the top of the timber, and also into the solid coal at the face and tapered off to a point in the last 6 ft. Below that taper the cavity would be about 8 ft. square. The amount of coal displaced was 75 tons and the volume of gas given off during six hours was estimated as 750,000 cubic feet (see Fig. 3, page 445).

Decided That It Was Unsafe To Extend Mine

After this outburst an inquiry took place, and in the end the management and three Government officials decided not to advance the levels any farther as there seemed to be no certain means of anticipating these outbursts. However, the mine was not closed down immediately. Some of the upper pillars were still worked until the railway company, which was using the coal for its locomotives, found it was of too small size to suit its requirements.

Moreover, the other collieries at Coal Creek and Michel were able to supply all the coal which the market needed. The coal seams of this part of the coal field, having been much altered by crushing and heat, would not make a good metallurgical coke; and this formed a further reason why operations were suspended.

Up to the date of writing outbursts of gas of such great intensity have not occurred at any of the other collieries in this coal field, and therefore it would seem that at Morrissey the special conditions of heat and pressure to which this end of the coal field has been subjected have not yet been found in other parts of the field.

The nearest approach to these disturbed conditions has been met with in the working on the south side of Michel Creek, where the strata are much disturbed by a severe twist. In this portion of the coal field large volumes of gas are driven off almost continuously, as set out in some detail in a paper read by the Chief Inspector of Mines of British Columbia before the U. S. A. Mine Inspectors' Institute at Joplin, in June, 1916.

He then stated that in old No. 3 mine on the east side of the slope as much as 15,695 cu.ft. of methane per ton of coal mined had been given off, resulting in the whole of the return air current being charged with methane to the extent of 2.66 per cent. as ascertained in actual analysis at Ottawa by Dr. E. Haanel. In the same part of the mine, when it was not at work, the percentage of methane in the air was 2.18. In the whole of the return air current of 60,000 cu.ft. per minute when the mine was not at work the methane content was 1.83 per cent.

In No. 3 East mine it is noticeable that the greatest

*An abstract from a pamphlet entitled "Outbursts of Explosive Gases in the Crowsnest Pass Coalfield, British Columbia."

yield of methane was from the west side, and it would therefore appear that the special conditions which caused these abnormal emissions of methane must be situated somewhere between the old No. 3 and No. 3 East. On Aug. 3, 1915, while the mine was at work, the west side split contained 3.33 per cent. of methane or, as calculated, gave off 7392 cu.ft. per ton mined.

The highest reported percentage of methane per cubic foot of air, found while the mine was at work, was 3.83 in old No. 3 mine. These mines were worked by two shifts of eight hours each, and the average volume of methane per ton of coal mined, calculated from mine samples of the main returns, was 4326 cubic feet.

These figures are certainly extraordinary, and it is not surprising to find that when an explosion occurred Aug. 8, 1916, in No. 3 East mine, that so serious was the damage to the mine that the body of one of the men killed has not yet been recovered.

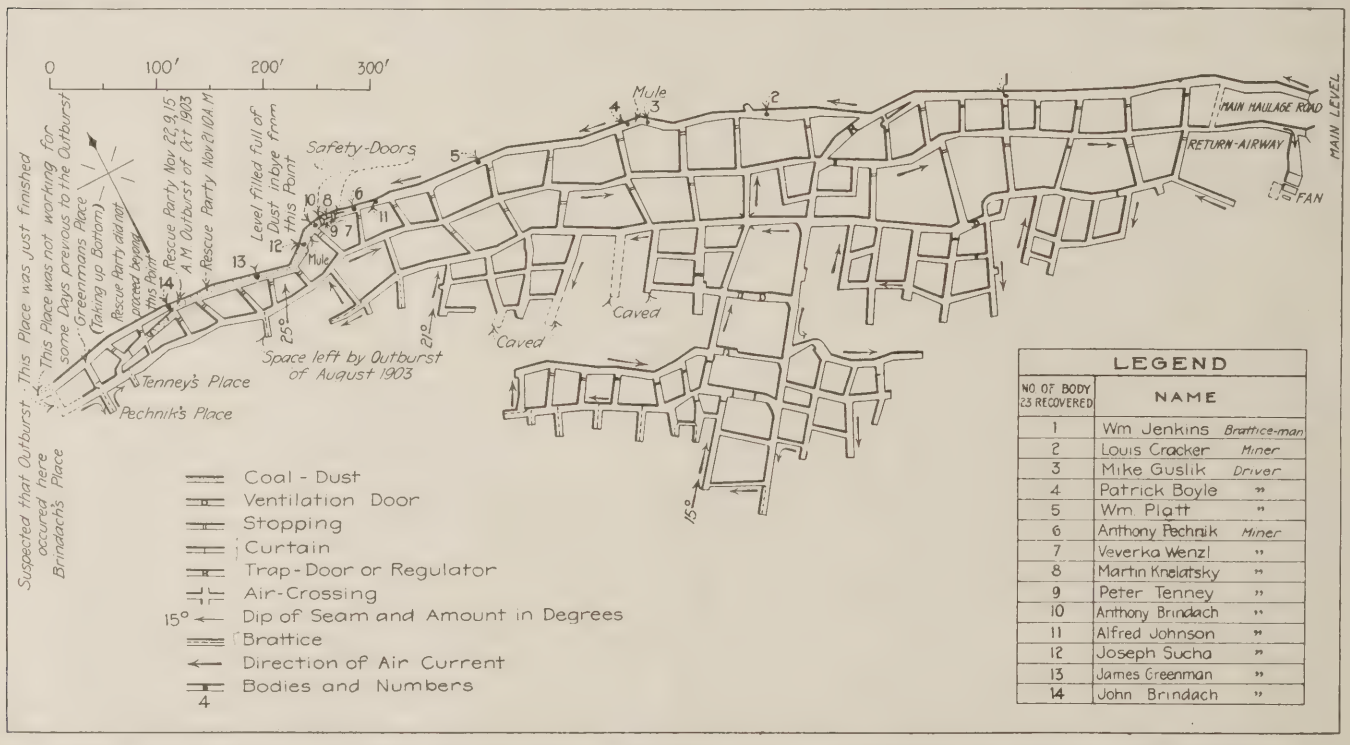


FIG. 1. PLAN OF NO. 1 MINE, MORRISSEY COLLIERIES, CANADA, SHOWING EFFECTS OF GAS OUTBURSTS

The average thickness of the coal in No. 3 mine is given as 5 ft. and of No. 3 East as 11 ft. Both seams are bituminous and will make excellent coke without washing. The analysis of the coal from No. 3 mine is stated to be: Moisture, 1.01; other volatile matter, 20.95; fixed carbon, 71.00, and ash 7.04.

Both of the coals named are very friable, and, in the mining of them, explosives can only be used in limited quantity. The cover is about 1200 ft., in which thickness there are several other workable seams. It would appear, however, from the data thus far collected that the main volume of the methane emitted is principally built up in the coal seam itself or in some part of the coal seam.

While making an analysis of the gases occluded in the coals from this coal field it has been discovered—and the point is important—that they consist in part of gases of the higher hydrocarbon series. The gas, though usually described as firedamp, is not necessarily methane only. This is an important point to take into account, and in 1904 I came to the conclusion that some part at least of the gas given off in the large outbursts is "wet" gas, and is similar in every way to the wet gas given off, say, at the Dingman oil well in Alberta. From this well a percentage of gasoline is (or was) collected.

I believe, as I did in 1904, that some of the gases in the coals are in liquid form, and thus when the restraining pressure is reduced as the covering coal is removed, they volatilize and force away the coal in the finest of dust, and in this manner file out long cavities of irregular form (Figs. 2 and 3) which remain after an outburst has been dissipated. It is very noticeable that the dust found in these mines under ordinary circumstances is of a greasy nature, and that the higher hydrocarbon gases are found occluded in it.

Sudden outbursts of gas have received comparatively little notice either in British Columbia or elsewhere, but in May, 1919, a bulletin of the Canadian Mining Institute contained an interesting paper by D. B. Dowling, of the Dominion Geological Survey staff, on "Some Possible Chemical Changes in the Formation of Coal." He says:

> Experiments with pressure alone do not give results, since great periods of time are required; but when implemented by heat, there is evidence that there is a chemical change made by which the increased percentage of carbon is attained with very little actual loss of carbon.
>
> That there is an increased tendency to throw off gas with the rise in carbon percentage is acknowledged; and when it has reached its maximum the coal might in some instances be classed almost with such unstable compounds as explosives. There are accounts of slight shocks producing "blow-outs" of large dimensions in mines working the higher bituminous coals. This liberation of gas need not be considered as coming from pockets of compressed gas; but as following much the same course as an explosion of dynamite, which is simply the rapid rearrangement of atoms.
>
> It would seem probable that the formation of gas was

accompanied by a concurrent formation of a more stable coal compound, and when the alteration was violent the stable coal was brought along with the gas as dust. Dust not formed in this way, but from the operations of mining and handling the coal, should be considered more as a series of minute particles of unstable compound borne along by a small gas atmosphere of its own making, and therefore not easily laid by sprinkling, and only to be got rid of by ventilation.

Unfortunately, this paper by Mr. Dowling, as far as regards the foregoing quotation, did not elicit the

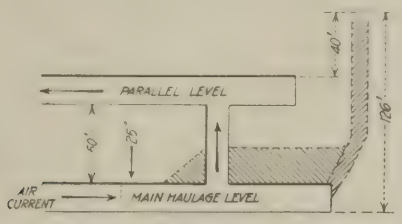

FIG. 2. COAL BLOWN INTO HEADING IN NO. 1 MORRISSEY OUTBURST OF AUG. 6, 1903

least comment and has remained as a dead letter. In the annual report of the Minister of Mines of British Columbia for 1909, the chief inspector of mines, Frank H. Sheppard, remarked on page 225:

> The question of dealing with these outbursts is the most important and difficult problem to cope with in this field. If this portion of the field is to be worked at all, it must be under conditions which will give the miner some chance for his life. Most of the outbursts in this field have been attended with loss of life.
>
> The whole question devolves upon the possibility of relieving the pressure ahead of the working face. If this cannot be done, it would be inhuman to ask or allow a miner to take chances such as are not experienced in any other industry. If the field is valuable, and this may be readily conceded, it would appear that the operator could go to considerable expense in experimental work, having for its object the safe winning of the field and the protection of the lives of those who may engage in its development, and it would be a reproach to modern engineering skill to admit that the problem will not admit of a reasonably safe solution.

When we wish to cure a disease the first and most important point is to diagnose it correctly, and similarly, in this serious problem of sudden and violent outbursts of explosive gases, we need if possible to find out when to expect them, and secondly, how to deal with them in safety. The need of experimental research into practical matters of this sort needs no emphasizing, because the lives of hundreds of miners may depend on their solution; and moreover, it may be anticipated that the problems will increase in importance as the mines extend farther away from the entries, and where large areas of goaf are closed off.

Up to the present no system of working has been consistently followed. Pillar and stall has been the usual method, and this has introduced the question of the proper size of the pillars, especially where "bumps" have been of frequent occurrence. In the latter cases it cannot be averred with any confidence that large pillars have given any better results than medium or small pillars; but there is no doubt in my mind that no system has given such excellent results as longwall.

There are many instances where pillar and stall has been the system adopted; this has later been changed to longwall, and this in its turn has been changed back to pillar and stall. In some cases the reasons given for the adoption of pillar and stall have been that this system gave the minimum of expense in moving dirt; in another case that there was not sufficient material to form substantial packs, and where there was material with which to build packs, that the cost of making them was entirely prohibitive due to the insistence of the miners' union officials that the miners should receive for "clod" a fixed price per inch thick, for each square yard removed.

It is of course possible to have a special gang of men to build the packs, but where it is possible it is better for the miners to build their own. In longwall working it is of the greatest importance to control the settling down and breakage of the roof, so as to maintain as regular a pressure as possible on the coal face.

In workings of longwall type, where gas in the floor gives trouble, it naturally escapes over a large area and does not break out in sudden and dangerous volumes, as it frequently does in pillar-and-stall working. Dangerous "bumps" seldom happen in longwall working after the first roof break has occurred, and therefore it is fair to conclude that bumps are mainly due to a combination of causes—the settling of the roof and the gas in the floor.

As there are several modes of working a mine on the longwall principle it is necessary that the management should choose that one which will give the lowest cost of extraction, and he should not be in a hurry to change the mode of working just because a few heavy roof settlings occur. The success of longwall working

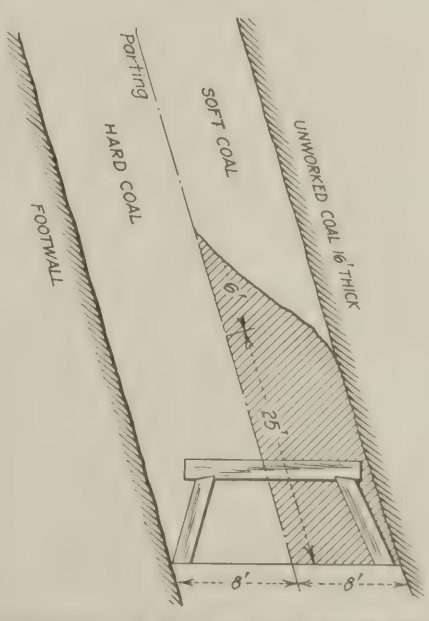

FIG. 3. OUTBURST OF MAY 19, 1909, AT MORRISSEY NO. 1

depends on the regularity of the breaking down or bending of the roof, or as it is often described, "roof control."

The longwall method of mining coal has another most important feature to recommend it, namely, that the mine is much easier to ventilate and therefore much safer and requires less brattice cloth. In longwall working the greatest trouble is experienced when the roof and floor are "very good," for they must be made to either bend or break.

In mines such as those in the Crowsnest Pass coal field it is advisable in many cases to drill holes in the floor, particularly where rolls or faults are met with, and thus relieve the tension of the floor gas.

From the soft nature of most of the coal seams in the Crowsnest Pass and the absence of "backs," "slines" and natural partings, which are common in many coal fields, these coals drain slowly, and this fact is a principle cause of the abnormal outbursts of explosive gases.

Since writing the foregoing notes the official report on the explosion in No. 3 East mine at Michel, on Aug. 8, 1916, has been published in the Minister of Mines Report for 1916. This states that the explosion occurred during a heavy thunderstorm, and shortly after the night or repair shift had gone into work at 11 o'clock. From the card that automatically records the water gage of the fan it is calculated that the explosion occurred about 11:20. No one outside the mine actually heard the explosion, or if they did, the noise was assumed to be caused by thunder. A miner who had just come out of the mine, and was on his way home, it was afterward learned, did not realize that an explosion had occurred.

Fan Engineer First to Learn of Explosion

The discovery was not made until the fan engineer, who had two fans under his care, visited No. 3 East fan and found wreckage in the engine room and other evidence of an explosion. The main entry to the mine was completely closed, and the exploration party had to go in through an old prospect opening. A fire in the main return airway from the east side was fortunately discovered and extinguished without further disaster.

The body of the fireboss was found some distance away from the remains of his safety lamp. It was assumed from this and other indications that the force had come from the main slope and not along the return airway. "The gauzes of the fireboss' lamp were badly crushed and showed evidences of alkali stain, as of the lamp having been heated." This would suggest that he had met with gas in the return air as soon as he had passed through the main separation doors; but his death was due to violence and not to burning, as his hair was only slightly singed.

The evidence showed that the miners had only just reached their working places when the explosion occurred. Thus the miners working in No. 6 slope face had undressed and put down their dinner pails and then returned to No. 13 parting to assist in rerailing a car left by the previous shift.

Careful measurements of the main return-air current from this mine showed that the air was saturated with moisture; that its volume was 120,000 cu.ft. with a velocity of 1500 cu.ft. per minute; that 2,194,560 cu.ft. of methane was given off during a working day, when 550 tons of coal were produced or at the rate of 3990 cu.ft. per ton of coal. The volume of the methane produced was calculated from the analyses of samples of air taken in the main return.

While testing samples of air from the Michel colliery, the Dominion government analyst, Dr. Haanel, has proved the presence of hydrogen and found indications which have shown "that hydrogen is not an uncommon constituent of mine airs." The presence of ethane has also been estimated as being one tenth of the methane present.

To those who have seen safety lamps tested in mixtures of hydrogen and air, it is not difficult to realize what dangerous conditions may arise when a miner entering his working place immediately hangs up his lamp on a prop without first making a test for gas. Miners as a rule do not appear to appreciate the importance of observing the law in this matter, as was shown during an inquiry into a more recent explosion in the same district.

The safety lamps in general use in British Columbia are of the bonneted Wolf-Marsaut type, burning gasoline or benzene. With regard to their safety, it is to be noted that Marsaut, while making his long series of tests by raising his double-gauze bonneted safety lamps into a quiescent explosive mixture of gas and air, did not consider such lamps as absolutely safe, and hence he added a third superimposed gauze which is the correct construction of the true Marsaut safety lamp.

It must be obvious to every reader of these notes that the necessity for devising some means to insure the better protection of miners' lives has now been amply demonstrated, and I therefore submit in conclusion that the time has arrived when these dangers ought to be carefully looked into by a special research commission or committee, and at as early a date as possible; and finally, that the system of developing and extracting such seams of coal as those referred to should be defined by such commission and strictly enforced by Act of Parliament.

Education—the Financial and Social Barometer

By R. Z. Virgin
Elkins, W. Va.

We are fighting a great war—the greatest conflict the world has ever known; and we are waging it upon a scale and in proportions greater than the most expert authority would have dared to describe a short time ago.

The corporations operating coal mines have been called upon to produce the coal necessary for the successful operation of manufactories that are working on war material; for our navy and army needs; for our transportation machinery; for our homes; and to make up the shortage in output of our Allies. All these requirements have multiplied many fold during the past year and will continue to multiply during the duration of the war. This unprecedented demand for fuel must be met, and this, too, while the supply of labor to produce it is being conscripted for war work or prompted by patriotic impulses is volunteering its services for duty overseas.

This condition, coupled with complex problems of transportation, is more serious than most readers imagine. The solution must be worked out by men of mature experience and judgment, in order to get the maximum energy and output in the minimum time, and simultaneously conserve the lives and limbs of the workmen; also to conserve our coal resources with the greatest caution.

By educators and mining men such questions as the following are asked frequently: "How can this be done?" "What would you advise?" "What are your ideas of solving this important problem?"

The answer is, "Educate the workmen." Education is the greatest producing agency in the world and makes for 100 per cent. efficiency. The days of the hill-top mines are gradually drawing to a close, and with deeper mining, more machinery, more elements of danger, a larger need for the coal, less men to get it with, and the men who would manage our mines through advancement in the regular course of promotion going to the front, we must do something, and do it quickly. Otherwise we will not have sufficient men in training to officer our mines when such officials are most urgently needed. Many of the large corporations are training their own men to officer their works; and they pay them salaries while they are learning the things necessary to enable them to properly discharge their prospective duties.

Almost every newspaper carries high encouragement to men who would make good in their particular line. The Bell Telephone Co., the Western Union Telegraph Co., and many other concerns have adopted this plan, and our Government is training thousands of men to officer the army and paying good wages for the time spent in learning. What is the mining industry doing toward educating its workmen for responsible positions?

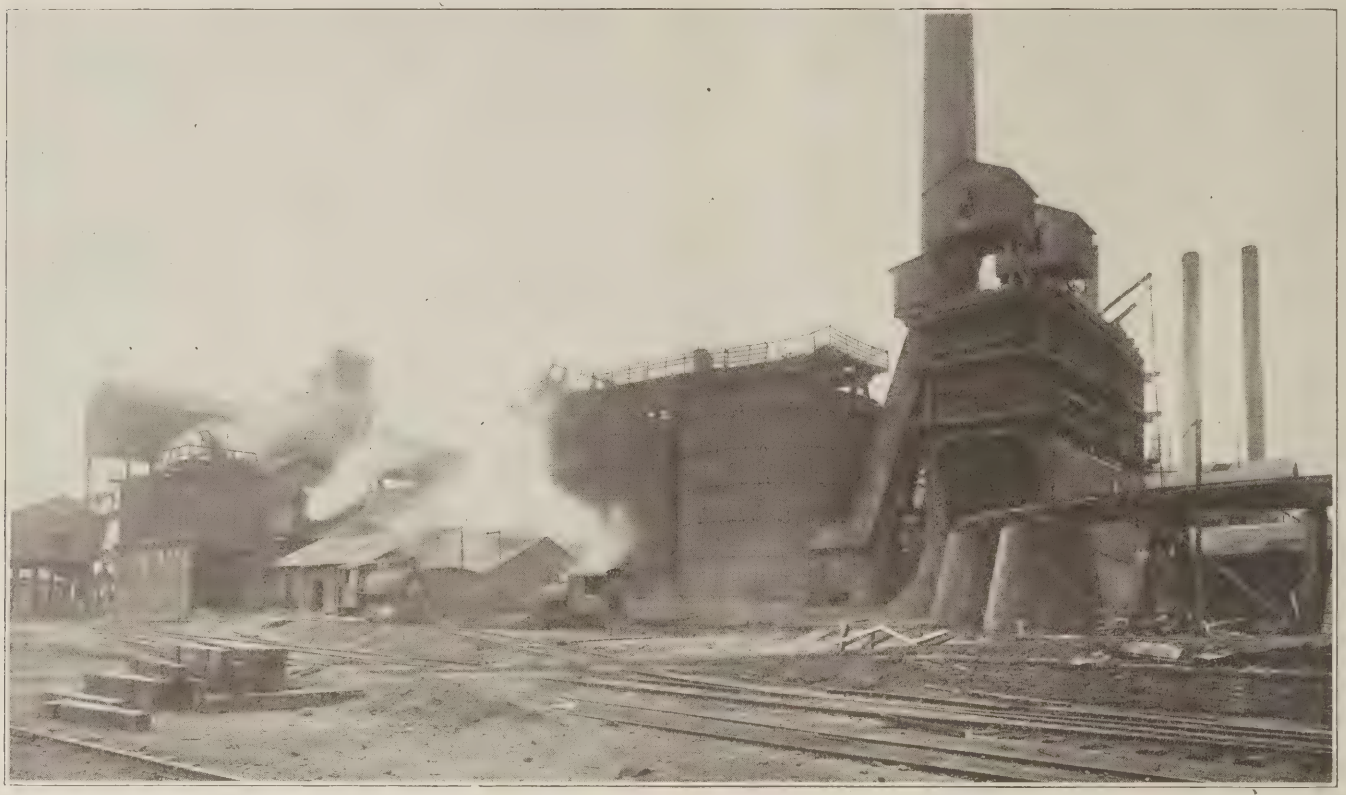
Mines Losing Their Younger Men

The men of the mines between 21 and 30 years of age, the material for the very best officials, are gradually being called to the colors, leaving, to fill their places, men of more mature years—those past the usual age at which men attend school. These men must be educated. This is no longer a question of how it may be done; but it must be done, and at once, if we expect to get out the coal that is demanded of us and keep our death and accident rate down to a minimum. It would never do to officer our mines with inferior men and bring about an accident rate equal to the death rate in the army. Many workmen yearly meet death in our mines during normal times, and an inferior class of officials would not lessen this death rate.

It is true we have our night schools, our first-aid classes, our moving pictures, etc., illustrating the right and wrong ways to do work in our several plants. The men of the mines willingly give up their leisure time and sometimes their sleep (depending on which shift they work) in order to obtain an education along their respective lines of work. But one night a week, or perhaps one night in two weeks, is far too little to accomplish our purpose in the time at our disposal. Again, while the men discuss problems among themselves they have ordinarily no one to refer their questions to, and the result is they fail to get far in their studies.

The State of West Virginia realizes the importance of the education of her miners, and has appropriated a sum of money for the expenses and salaries of vocational teachers, who work under the direction of the officers of the State University. These instructors give lectures and practical demonstrations to workmen at about 10 different points, which they reach about twice each month.

I am of the opinion that mining companies will soon come to the point where they will follow the trend of other industries, and pick out ambitious men and school them at their own plants, five or six days a week, pay them while learning, and not require them to study on their own time after work. A large company employing several hundred men would be in a position to secure a competent teacher, who could probably visit two plants per day, holding school in the forenoon at one, and in the afternoon at the other. Thus no workman would need spend his evenings after work in school, but could rest at home with his family and have time for thought over his previous lesson, on his own porch or in the comfort of his own rocking chair.



If we look at the pitiable condition of Russia, with its illiteracy in all degrees, we can judge from our own condition by comparison, that education surely pays large dividends. We can no longer say, "Look what we are doing for our workmen now, in comparison to what we were doing a year or so ago." A brand new condition is upon us. We must see things through new spectacles, and ask ourselves, "Are we doing the same, or more, for our men than other industries are doing?" We can no longer be tolerated when we say, "I did not get anything when I dug coal, unless I worked hard for it, and nobody did anything for me."

This is a revolutionary period. The foregoing statement applies in coal mining as well as in other industries, hence we are called upon to do things we never dreamed of before. We must therefore educate our men, or go backward. It would be decidedly un-American if we failed to keep pace with progress. The several responsibilities thrust upon us during this crisis must be met with the best there is in us. We will then find that the social and financial barometer is education.

Combustion in Commercial Furnaces

In commercial furnaces the combustible gases and the oxygen seldom form a perfectly uniform mixture, hence the rate of burning is not altogether controlled by the law of mass action but largely by the rate of mixing. This is especially true of the furnace gases near the surface of the fuel bed. The combustible gases leave the fuel bed in a solid stream containing little or no free oxygen. To this stream of combustible gas air is added through the firedoor or other special openings. If this air is added in comparatively large streams that are not agitated, the streams of combustible gases and the air may flow through the furnace for some distance in more or less stratified streams, and the combustion takes place only along the surfaces of contact and be slow. Such combustion makes itself evident as long flames. When the air is added in a large number of small streams, or when the large streams are agitated so that they break into a large number of small streams, the surface of contact is large and the combustion is rapid, approaching the velocity of combustion of a uniform mixture. —*Bureau of Mines Bulletin No. 135.*

Homemade Fuel

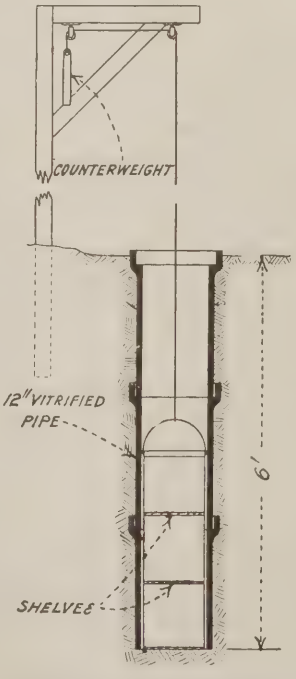
The accompanying illustration does not show a tempting pile of doughnuts at some Y. M. C. A. hut "somewhere on the western front" in France. It is anthracite fuel made by hand in Wilkes-Barre, Penn. M. S. Hachita, chief chemist of the Lehigh Valley Coal Co., was responsible for this addition to the fuel resources of the region, and *Coal Age* is indebted to him for information about the manufacture of the fuel illustrated.

It seems that in Japan much charcoal is made and considerable fine powdered material results from the handling of this product. The fine charcoal is utilized by mixing it with 25 per cent. of clay and moistening

ANTHRACITE FUEL MADE BY HAND

the mixture with just enough water to permit balls to be formed by hand. The clay acts as a binder. When dry this fuel is burned similar to other combustibles. Having this in mind, Mr. Hachita experimented with the fine coal dirt which collects in streams in the anthracite field at places where pools form. At such spots in the river flowing by Wilkes-Barre, coal dirt in its finest condition may be found.

In river dredging at the place noted about 15 to 30 per cent. of clay is mixed with the fine coal. The practical point about it is that this coal is where everyone can use it and have an opportunity to secure a supply of fuel. Just as it comes out of the water it should stand for a while, to drain off surplus moisture. When it reaches the consistency of mud which can be readily shaped up by hand into balls about 2 to 2½ in. in diameter, it is ready for manufacture into fuel. When molded into shape it should dry in the air for several days, after which time it may be handled with a shovel.



There are no special difficulties connected with obtaining a supply of this material at many of the streams throughout the anthracite region. A double purpose would be achieved in the utilization of this fine coal from the creek beds. The companies directly interested would have their creeks dredged and the people doing the work would get a coal supply for a nominal sum.

In using these coal balls in an ordinary stove, the fire can be started the same as with ordinary briquets —they burn much the same way. As the balls burn they get harder; the moisture is driven off and they harden similar to bricks under manufacture. The ashes resulting can be worked out of the fire much the same as in the case of an ordinary coal fire. The burning balls also can be stirred with little danger of their breaking. The facts noted in connection with the utilization of this creek coal mud are not merely the results of laboratory experiments. The method described, from start to finish, was worked out by Mr. Hachita and pronounced a practical success. If followed by the people who can readily obtain the raw materials, they will secure a fuel supply which can be stored against a time of scarcity of coal. It is another patriotic effort which will be effective in proportion to the amount of this waste product which is worked up into available fuel. It should not be shipped any great distance, as its high ash content would be wasteful of transportation facilities. But it will release for transportation coal needed for domestic consumption at distant points. Also it is doubtful if the balls would stand much handling in bulk.

On a large scale the material could be cut out with a shovel into cubes six inches on a side. It could be handled similar to peat, to which it approaches in regard to amount of heat available on combustion. Clay has been used as a binder in briquets, but it adds much impurity to the fuel made by this method. Therefore it would find its chief field of usefulness close to the point of manufacture. Reference to this matter is made at this time as possibly offering some suggestion as to the mechanical handling of fine coal on a commercial scale. During times of fuel famine some processes may find application which were discarded at other periods of fuel overproduction. The benefits of saving and conservation are assuming special importance at present.

To Keep Workmen's Dinners Cool

At the Dayton flood-prevention work, coolers, consisting of three lengths of vitrified pipe set vertically in the ground, are used to form a well into which a dinner pail can be lowered by a rope and pulley. This serves to meet the problem of the absentee iceman, says *Engineering News-Record.* Three lengths of drain pipe will line a well 6 ft. deep, as shown by the drawing. At this depth the ground is as cool as the inside of the ordinary refrigerator. To contain the food, a tin bucket 11 in. in diameter and 3 ft. high is fitted with shelves and a full-length hinged door. The bucket is also provided with a bail for handling. Two pulleys, a length of rope and a counterweight complete the outfit. Ordinarily the pulleys are fastened to the shed roof of the kitchen, but a post and bracket like those here illustrated may be employed with advantage. Any tinsmith can make the bucket, using inch boards for the shelves. This "iceless refrigerator" was devised by H. H. Rupe, superintendent of carpenters at the Englewood reservoir.

DINNER PAIL COOLER

Poor Car Supply Hampers Production

Efforts to stimulate coal production are being offset and hampered by irregular and inadequate car supply. While the figures from the Railroad Administration indicate a great improvement in this particular, they are misleading. After having had Saturday night, Sunday and Sunday night to handle cars, the railroads frequently are able to have on mine sidings 150 per cent. car supply. On Tuesday and Wednesday they often are able to keep the car supply above 100 per cent. By Saturday, however, car supply probably has dropped to 50 per cent. By totaling the six days, the railroads show a good percentage of cars. The figure is misleading, however, as the mine can utilize only 100 per cent. of cars and the excess early in the week is of no advantage.

Great enthusiasm has been aroused among mine workers in numerous cases recently when all previous records of production have been broken. Enthused by such a performance everything has been ripe for a determined effort to keep up the rate of production, only to have the whole plan spoiled and enthusiasm permanently dampened by a complete fall-down on the part of the railroad to supply the necessary cars.

It is noticeable that while every one concerned in the coal-mining industry is active in an effort to raise the morale of the workers to an unprecedented height, no such activity is in progress among the employees of the railroads. If every employee of the transportation lines could be imbued with earnestness to get the maximum efficiency from every coal car, it is believed that car supply would soon cease to be the principal limiting factor in the production of coal.

Coal the Paramount Lord of Industry

As a part of its effort to stimulate production, the Fuel Administration is circulating in all coal-mining districts the following extract from an address by Lloyd George to representatives of mine workers in the United Kingdom:

The blood which pulses through the veins of industry in this country is made of distilled coal. In peace and in war King Coal is the paramount lord of industry. In war it is life for us, and death for our foe. It makes the material and the machinery which it transports. It fills weapons of war. Cannon means coal. Shells are made with coal; shells are filled with coal. The very explosives inside them—coal; and then coal carries them all right into the battlefield to help our men. Coal is the most terrible of enemies, and the most potent of friends. There have been in this war 350,000 casualties of British soldiers inflicted by German coal—by the Westphalian miner working in coöperation with the Prussian engineer, without stint, without reserve, without regulation, putting their strength at the disposal of their Fatherland. It is coal that caused those casualties. Yes, and when you see the seas clear, and the ocean over which the British flag flies with impunity from realm to realm and from shore to shore, when you find the German flag vanished from the face of the seas, who has done it? The British miner helping the British soldier.

We must pay the price of victory if we mean to get it. Victory has its price. We have but one question to ask ourselves, of all ranks, of all grades and trades. Are we doing enough to secure victory? Because victory means life for our country. It means the fate of freedom for ages to come. There is no price which is too great for us to pay which is within our power to pay. Freedom implies the right to shirk. But victory is not in that road. The trenches are not all in Flanders. Every pit is a trench in this country—a labyrinth of trenches. Every workshop is a rampart, every yard which can turn out munitions of war is a fortress. Picks, shovels, lathes, hammers—they are as much the weapons of this great war of European liberty as a bayonet, a rifle and a machine gun; and the man who does not handle them with all his strength is failing as much in his duty as the soldier who runs away from the battle at the front.

Cardinal Gibbons Would Honor Miner Who Stays at Work

Cardinal Gibbons wants to see the same honor accorded to those who mine coal as is given to those who actually face German bullets. He has written a letter to Dr. Garfield which, it is believed, will have great weight with mine workers. The letter in full is as follows:

I have read with great pleasure the proclamation of the President of the United States with regard to the fuel situation. Like a great many other Americans I have been very much alarmed at the outlook for next winter. It is to be hoped that those whose business it is to get coal out of the earth will see how much depends upon their labor, and what a patriotic work they perform in providing that which is really at the present time the sinews of war.

The very fact that we have conscription puts a responsibility on every man in the country either to fight or to work, as the Government may think most necessary for the public good. The very fact that certain kinds of workers are put in a deferred classification is to my mind an indication to them that their real duty is to do that particular kind of work, because through the particular kind of work which they can perform the country will be more greatly helped and the war more easily won. But just as it is the duty of those who are called to fight to fight bravely and to allow their patriotism to be the informing principle of their courage, so is it necessary that those who work should work in the same strenuous and patriotic manner.

There are, I think, two classes of people who can help very much in this regard. The first class is composed of the families and neighbors of the men who are put into a deferred classification. As the President has so truly said, these people should treat the men who are working when often they would much rather be fighting, with the greatest respect, and should show that they recognize and honor the patriotism which holds men to their posts in the coal mine as well as the patriotism which holds a man firm in the trenches.

The other class which I think could be of very great assistance at this time is the clergy, and I sincerely hope that every minister of religion, especially in the mining districts, will put before his congregation the great principle that patriotism is devotion to country; that those who love their country must serve ther country in the most acceptable way, and must give their services, not where they would choose, but where the Government thinks they could be most useful; and that those who do stay behind to work must remember that they are working for their country and are holding up the hands of their countrymen now fighting across the seas, and that therefore they must put every ounce of energy and manhood into the work which they are asked to do.

I hope for the very best effects from the President's proclamation.

"Tuckahoe" Breaks All Previous Records

On her last trip to Boston, the "Tuckahoe" went in and out of port, discharging nearly 5000 tons of coal in 31 hours. This is several hours under the time any other collier has taken at the port of Boston during this month. The average of 19 ships discharging at Boston during the half week of the "Tuckahoe's" visit, Aug. 5-8, was 135 hours and 54 minutes. During the half week ending Aug. 15, the fastest time in and out of Boston was made by the "Lake Duncan." She was 34 hours and 8 minutes in port. The average of 25 ships discharging at Boston in that period was 124 hours and 48 minutes.

The port performances of the best colliers in the New England trade, compared with the average of all colliers in it, for the half-week ending Aug. 12, were as follows:

Loading Ports—Baltimore, average of seven ships, 60 hours, 54 minutes in port. Best ship, "Tampico," 30 hours, 54 minutes in port. Norfolk and Newport News, average of 12 ships, 34 hours, 42 minutes in port. Best ship, "Bay View," 18 hours, 42 minutes in port.

Discharging Ports—Boston, average of 21 ships, 116 hours, 30 minutes in port. Best ship, "Northern Queen," 49 hours, 54 minutes in port. Other discharge ports, average of 17 ships, 100 hours, 18 minutes in port. Best ship, "Bay State," at Providence, R. I., 42 hours, 6 minutes in port.

To Rush Supplies to Coal Mines

The extent of the difficulties being experienced by mine operators in securing supplies is being realized for the first time with the establishment of the Mine Supply and Equipment Section of the Production Bureau of the Fuel Administration. This section was recently created with Roy A. Rainey and David D. Bush in charge.

Information regarding inability to secure supplies already is reaching the bureau in large volume. The number of complaints is increasing daily, as it is becoming known more generally that the Fuel Administration is giving specific attention to this work, so that no production may be lost through delays in receiving supplies.

In addition to looking after priority matters, Messrs. Rainey and Bush are giving equal attention to matters of transportation. By their aid, supplies and equipment are moved through embargoes and otherwise expedited while in transit. Through their close coöperation with the War Industries Board and the Railroad Administration, they are able to eliminate much of the routine procedure which otherwise would be necessary.

The Mines Supply and Equipment Section can not undertake the tracing of freight. It will be incumbent upon the operator to ascertain where his shipment is being delayed and the nature of the cause for its delay.

Applications for Opening New Mines Now Being Considered

Consideration now is being given to the 700 pending applications for permission to open new coal mines. These applications are being handled by a committee headed by Frank G. Jones, of the Fuel Administration. Mr. Jones states that each application is receiving exhaustive consideration. The sole thought in their consideration, he points out, is to increase the production in the near future. Many applications can not be granted, Mr. Jones declares, because the same labor utilized in an operating mine would produce more coal than could be secured from a new mine. Another important question which has to be determined is whether the railroad serving the mine can handle a greater tonnage. These are the most important questions which must be settled after it has been ascertained with reasonable certainty that the mine to be opened is likely to become a producer. Only when convinced that a new operation surely will increase production of coal will permission be granted to open a new mine. To date, 215 bituminous applications and 9 anthracite applications have been approved.

No Pledge Required from Coal Industry

In the affidavit required for the securing of priority, reference is made to the pledge required by the priorities division of the War Industries Board. No such pledge is required from the coal industry, and no operator need hesitate in the execution of the affidavit on that ground.

Defines Meaning of Word "Replacement"

In paragraph (p) of the regulations governing priority in production, the use of the word "replacement" has given rise to misunderstanding. The paragraph reads as follows:

"(p) For the operation and maintenance (not new construction, expansion or replacement) of coke oven plants, mines, smelters, furnaces, rolling mills, wire drawing mills, pipe and tube mills, employed in the production of fuels, metals and metal products—A-6."

"Replacement" in the sense used in no way refers to repair parts. The priorities division has issued a formal ruling to that effect.

Irregular Car Supply No Excuse for Drop in Coal Production

Because car supply may be irregular and at times inadequate is not regarded at the Fuel Administration as a legitimate excuse for slowing down production. A few operators have replied to appeals to stimulate production by asking the value of trying to increase production when they are without cars so much of the time. One hundred per cent. Americans, keenly anxious to win the war, will find a way of meeting such a situation without allowing production to slow down in the least degree, says the Fuel Administration.

Anthracite Production Grows

Anthracite coal production for the week ended Aug. 24 showed an increase of 167,600 gross tons above the record for the preceding week. The total output, according to estimates of production furnished by the mines to the United States Fuel Administration, was 1,706,016 gross tons, compared with 1,538,416 gross tons for the week of Aug. 17, 1918, and 1,589,454 tons during the corresponding week of 1917. Of the total tonnage, 1,126,677 gross tons was prepared and pea sizes and 579,339 gross tons steam sizes.

The average production per working day for the week amounted to 284,336 gross tons, compared with 264,909 gross tons during the corresponding week of 1917. The estimated total production for the coal year beginning Apr. 1, to and including Aug. 24, is recorded as 33,384,380 gross tons, as compared with 32,689,219 for the same period during 1917, an estimated increase of 695,161 gross tons.

Great Fuel Saving in Connecticut

The administrative engineer of the Bureau of Conservation of the United States Fuel Administration in Connecticut reports that those industrial plants which have furnished answers to the fuel saving questionnaire are, in a majority of cases, making the changes suggested in the power-plant recommendations. Eighty plants, consuming for the year ending May 1, 1918, practically 337,000 tons of coal, as a result of the conservation changes suggested will save at least 15 per cent., or over 50,000 tons of coal, annually. This state had previously reported from similar sources an annual coal saving of approximately 31,000 tons.

The administrative engineers in Michigan, Kansas, Georgia, North and South Carolina and Florida have reported marked savings of coal in industrial plants as a result of the practical demonstrations of conservation.

Records Broken in Connellsville Region

Where the car supply has permitted, there has been marked stimulation of energy in bituminous coal-mining regions. A report recently received by James B. Neale, Director of Production of the United States Fuel Administration, is to the effect that for the week ending Aug. 23 the Connellsville field showed a production of 716,954 net tons, breaking all previous records for output for this district.

Coal Mines to Receive Necessary Power

Coal mines in the Pittsburgh district will not have to accept their pro rata share of the power curtailment. An order to this effect has been issued by the War Industries Board at the suggestion of the Fuel Administrator. Industry had expanded in the Pittsburgh district until the West Penn Power Co. was overloaded. This was followed by a breakdown in generating machinery. While coal mines are allowed their full quota of power from the West Penn Co., other war industries have had to curtail their outputs.

A questionnaire will be sent to coal operators within the next few days with the idea of ascertaining specific information with regard to those who derive their power from central electric power plants.

To Conserve Mine Material

Along with his efforts to secure priority for all needed supplies for coal mines, D. D. Bush, of the Fuel Administration, is taking steps looking to the closest conservation of mine materials. Information in his hands indicates that many wasteful practices are being permitted. In addition to stopping wastes, he is calling to the attention of mine operators the good results which will follow the substitution of the less needed materials for those needed in the war program. Priority will not be granted for steel ties, if wooden ties are obtainable. The use of substitutes for steel roofing is being urged. An asbestos composition weather boarding, which can be used in place of galvanized iron or other more needed material, is suitable for covering and other buildings, it is being pointed out. Mr. Bush also is asking the operators to clean up their scrap piles and salvage every available pound of metal obtained.

Brief Washington Notes

R. R. Horner, C. L. Colburn and W. J. German, of the Bureau of Mines staff, have been commissioned captains in the engineer corps. Mr. German already is in France.

M. D. Edmonds, one of the editors of the Philadelphia *Public Ledger*, has agreed to give three months of his time to the Fuel Administration to assist in the campaign looking to increased production.

Saving of coal, running as high as 15 per cent. of the state's consumption, is being reported from several states as a result of economies effected at power plants, it is reported by the Fuel Administration.

E. E. White, production manager for the New River and the Winding Gulf fields, reports to the Fuel Administration that farmers in the territory under his jurisdiction are spending their days in the production of foodstuffs and are working overtime at night in the mines.

Vague reports from Europe indicate that after the war the world will be informed of some extraordinary developments in the utilization of bituminous coal in certain countries, and that these developments will become of pressing importance to manufacturers in the United States.

High Lights in the Coal Situation as Seen by the Cartoonist

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The union leaders are not disposed to let the wage-scale question die. It will be recalled that the district presidents of the United Mine Workers of America met on Aug. 22 and requested the Fuel Administration's approval of the reopening of the wage question in all mining districts. The petition said: "Again and again we will come to you in behalf of the mine workers." The union in effect put itself in the position of the creditor in Hindustan who sits on the debtor's doorstep till payment of the sum demanded is fully made.

The Fuel Administration promptly replied that it could not allow an increased wage. Dr. Garfield said that he had informed President Wilson, when the last increase was granted, that there would be no more during the war, and in reply to what was said about bonuses he declared that he would correct the evil, where proved, by reducing the price limit. As a start he announced his intention of lowering the rate 20c. in the Ohio and Hocking fields and 5c. in all the other fields of Ohio except the Eighth district. He did this because it was from these points that he received most complaints about bonuses.

LABOR LEADERS EMPHASIZE HARD-COAL WAGE

At first the leaders appeared disposed to regard the decision as final, but pressure from the anthracite region developed, and on Aug. 26 they made representations to Dr. Garfield urging that the hard-coal mine workers deserved consideration even if the scale in the bituminous region was not to be revised. They pointed out that the rate of pay in the anthracite field was lower than in the bituminous region.

There is some humor in the situation. The miner in the bituminous region got an increase in his wage rate because he could not live with unsteady work—two or three days a week—if he were merely accorded a fair fate of pay. Now the anthracite mine worker edges up and says that the bituminous mine worker is getting more pay per day than has been granted to him. Soon we will hear from the bituminous mine worker. He will assure us that as his work is irregular his monthly wages are less than the monthly wages in the anthracite region and are therefore too low.

LABOR PROGRESSES BY DRIVING SALIENTS

In this way wages work their way upward. The man with the low daily rate believes he is wronged, and as soon as that is corrected the man with the lower monthly rate is heard from. So it goes. A similar seesaw is found in the payment according to the difficulties in coal extraction. For hard or thin coal a differential is demanded, because the miner cannot make a living in such a tough or tenuous measure. Then when he has obtained the increase demanded the man who has the softer, thicker coal cannot see why the operator with coal having such advantages cannot afford to pay him the higher rate per ton.

The mine workers in this way drive salients into the line only to consolidate them later into a continuous front. If, by its unrest, labor only fought a real enemy it might be congratulated. But when it bites, it bites itself, as spiders are said to sting themselves to death. The consumer must pay the increased cost of production, and, as workingmen are themselves consumers, in the long run the workingman must pay the increased wage demand.

The anthracite union leaders declare that the mine production will suffer if work in the mines is not made more profitable. If only the munitions industry would bear more kindly with irregular workers it would get quite a few of the less diligent who now stay at the mines largely because of the laxity of mining rules. Unfortunately, the steady work at higher pay is a great incentive to the steadiest of men, whom the coal companies are trying most earnestly to keep on their pay rolls.

The Federal and state employment bureaus are trying to save the day in the anthracite regions by hunting up the loafers and sending them to the mines for work. Men who have been getting their living by their wits or have depended on their relatives for their subsistence have been carefully listed, and they are being diligently rounded up by the authorities. The coal company officials have declared their intention to accept the men as fast as they are escorted to the mines. All who fail to turn up at work will be reported to the proper authorities.

"WORK OR FIGHT" BEGINS TO HAVE MEANING

The Philadelphia and Reading Coal and Iron Co. has appointed men to visit the homes of the company's employees whenever the men are idle. They will ascertain just why they fail to report at the mines. Where the only reason is dissipation that fact will be reported to the proper authority. It is said that if labor cannot be recruited around the hard-coal regions, men will be imported from such Western States as have no labor shortage at the present time.

At the Sandy Run colliery of M. S. Kemmerer & Co. 75 men struck on Aug. 22 to induce the company to pay their daily transportation charge between Freeland and the mine workings. Sandy Run is in the southern part of Luzerne County.

The day before the strike just mentioned saw the end of the strike at Williamstown, which, as will be recalled, is in the Lykens Valley region to the southwest. The mediators of the Bureau of Labor on Aug. 20 visited this mine with the intention of ending the strike. As stated last week, the drivers at this colliery were asking wages equal to those accorded to drivers in bituminous mines. The difference had closed down the mines for a full week. The compliance with the demands of the Bureau was immediate. The men went back to work on Aug. 21. Promise was made that a conference at Washington between the drivers' representatives and the operators would occur sometime during the present month.

MORE DISSATISFIED MINE DRIVERS STRIKE

The driver boys at the Pine Brook Colliery, Scranton, Penn., of the Scranton Coal Co., have also been on a strike for a higher wage of 15c. per hour, and this has interfered with the production of the miners of that colliery, reducing the output 3000 tons per day. The miners are able to work only about half time.

A native of Germany, Werner Nowak by name, who after nine years had reached the position of mine engineer and superintendent of the Edwina Coal Co., of Garret, Somerset County, Penn., was arrested recently and confined in the Allegheny County jail as a dangerous enemy alien. It is charged that he alleged that "America will be glad to kiss the Kaiser's toe before the war is over. I am a German and will never take out naturalization papers."

At turbulent Colliers, a mining town in Brooke County, and in the West Virginia Panhandle, 275 mine workers recently went on strike. They were employed at the Locust Grove mine of the West Virginia-Pittsburgh Coal Co. The miners were formerly paid by the car and not by weight, at least each car regardless of its actual loading was paid for as having a certain number of pounds

loaded on it. The men demanded that they be paid by the actual weight each car contained and that a check weighman be placed on the tipple, all of which was done. But the foreign miners did not like the weight that the weighman entered. A series of tests by inspectors, union men and miners did not satisfy them, and they went on strike despite the orders of the union officials, who denied the allegations of the miners and forbade the resort to a strike.

Frank Ledvinka, the president of the subdistrict, announced during the strike that "there is no strike at Colliers as far as the United Mine Workers of America are concerned. The men are out in direct violation of our agreement. The strike has no sanction from the United Mine Workers." James H. Dahm and William C. Liller, of the Bureau of Labor, brought the mine workers around when the efforts of the union failed. The mediators made the mine workers sign a resolution pledging loyalty to the United States in the war.

Earn Labor Day by Working Overtime

At the opposite end of the state is the mine of Monongah, operated by the Consolidation Coal Co. There the miners had a much different spirit from the men in the neighborhood of Colliers. They felt they wanted to keep Labor Day and also that they did not want to see the tonnage suffer, knowing how badly it is needed by the transports, battleships and cruisers on the ocean. They agreed to accept the company's offer and they worked overtime on Friday and Saturday of last week, thus making up their full quota.

A different story comes from the same region, the Fairmont district. After reciting what the Monongah men have done we hesitate to tell the other story because it can apply to only a few men. It appears that a small minority of the men in the Tygart's branch of the Monongahela River have found life somewhat unendurable since West Virginia became bone dry and they have been distilling a spiritous liquor out of raisins. It is known by the euphonious name of "Old Hen." In order to stop this misuse of so harmless a comestible, the Food Administrator has been asked by the Harrison County Council of Defense to regulate the sale of raisins and grapes in the Fairmont region and provide for their sale in small quantities and for strictly household use.

Mines Too Near Benighted Pennsylvania

But this trouble is a mere circumstance to that in Monongalia County, for while Harrison County is well south of Pennsylvania, being protected by the width of two bone-dry counties, Monongalia County is so handy that wetness and even a genuine "soak" is attainable at the expense of a few cents for railroad fare or a few dollars to a jitney driver. The men of Monongalia County, of which Morgantown is the principal city, make weekly and even daily trips across the line to purchase intoxicants at Point Marion.

The prosecuting attorney is securing data to see just what effect the shocking wetness of Pennsylvania is having upon the production of Monongalia County.

From these men who have more interest in Old Hen and John Barleycorn than in the waging of the war, it is a pleasure to turn; for there are a number of extremely patriotic people in West Virginia. The Italians at Hepzibah, just north of Clarksburg, the principal town in that Harrison County where Old Hen is wont to be brewed, have contributed money each month to enable W. R. Butts, the president of the local, to tour the country and address meetings urging the miners everywhere to produce maximum tonnages. W. R. Butts has a son in the service and he loses no opportunity to preach the gospel of large production.

The funeral question has come up for solution at Page, W. Va., a village on the Virginian R.R. in Fayette County. The miners have adopted a resolution pledging themselves to produce as much coal as possible and to encourage others to do the same. They further resolved not to let a fatal accident in one mine affect the operation of another mine, and ruled that the death of a miner or a member of a miner's family, not due to a mine accident, shall not affect the operation of the mine. However, funerals are to be attended, as before, by a burial committee.

A. W. Calloway's mines in the Upper Potomac region have done their level best since the United States went into the war. Nowhere perhaps is the spirit of service more hearty than at the mines of which he is (or perhaps rather was) general manager, for he is too busy now to give them much care. Sergeant Lee Manchel of the British Army has been speaking at Thomas, Coketon, Bencush, Davis, Pierce, Henry and Kempton. Democratic, earnest and patriotic, the purposeful spirit of Mr. Calloway has done wonders to make the workmen of the Davis Coal and Coke Co. put their every effort into a support of the war.

Shorter-Time Strike in New River District

Before leaving West Virginia, a strike has to be recorded, this one in Fayette County. Somehow it is impossible to get along without these troubles. This strike is at the Kilsyth mine of the McKell Coal and Coke Co. At last report it has lasted seven days and had withstood an attack from the Fuel Administration without settlement. Apparently the miners want to change or, would it be more correct to say, to shorten the hours of work?

In Illinois, the Tuxhorn Mine, at Springfield, is still working irregularly because of the factional fights between the black and white members of the local union. Some time ago the local had an election and a negro was elected. The whites complained that the election was conducted unfairly, and a clash between the miners resulted. For a while work at the mine was stopped, but District Attorney Knotts urged the men to return to work. Then there was another election, and a claim was made that this was illegal, and the men quit work again. Part of them have returned to the mines pending a settlement of the controversy, the dispute being referred to State President Farrington.

Frank Farrington, who was invited to form one of an American labor body to visit England, France and Italy, has declined, believing he can do greater good boosting the production of coal and maintaining goodwill at home than by going abroad, pleasant, as he says, the trip would be. Alexander Howat, the president of the Kansas mine workers, is in Europe as a representative of the Socialists who favor the continuance of the war. A service flag with several hundred stars representing the mine workers in the tenth subdistrict of Illinois who have joined the army and navy was dedicated at the Labor Day demonstration at Johnson City. The Divernon, Ill., local of the United Mine Workers has received a banner from the state organization in recognition of its having made the largest contribution to Red Cross work in Sangamon County. The union has 78 members in the army and navy.

We are informed that the operators in Illinois have been asked by the local administration to keep close track of all absentees from the mines and of the reasons for deficient tonnage from whatever source.

From Alabama comes the grateful news that the miners worked on Labor Day. For many months the Alabama men have been disposed to work irregularly, but at last they have arrived at such a state of patriotic resignation that they are willing to work even on that labor festival.

Wanted Four Bosses To Stay in the Union

On Aug. 16 the Dominion Coal Co., at Sydney, Nova Scotia, offered to pay a bonus to shippers and loaders. The announcement was made to the Amalgamated Mine Workers' Union. On Aug. 25 the mine workers of the Nova Scotia Steel and Coal Co. in Sydney mines went on strike to compel four deputies to retain their affiliation with the union. The employees demanded that the deputies be discharged. These deputies formerly occupied an unofficial position and when raised to official rank they decided that membership in the union would prevent a proper discharge of their duties. They accordingly resigned. The company, through the general superintendent, Thomas O. Brown, stated that it was opposed to deputies remaining in the

union ranks, but did not recommend these men to resign. In fact, Mr. Brown rather blamed them for doing so. In consequence of a conciliatory letter from the management the men returned to work.

At the Brule coal mines of the Canadian Northern, near Edmonton, Alta., a strike occurred on Aug. 21 as a protest against the alleged unsanitary condition of the washhouse. The chief mine inspector, who visited Brule, is said to have confirmed the charges of the miners.

Miners Deny That They Are to Blame

Six hundred miners of Belleville, Ill., recently protested by resolution against the charge that the miners are to blame for the present coal shortage which threatens to become acute during the coming winter. The action was based on the report of a committee which had made an investigation of the car supply, and which reported that ten mines were idle in the Belleville field as a result of car shortage. The closing of the mines laid 1500 miners idle and cut the output for that day 15,000 tons. The committee reported that in the past month there had been a loss in output of 100,000 tons in the Belleville field, due to car shortage. The resolution concluded: "We, the miners of Local No. 99, consisting of 600 members, go on record as resenting all accusations and insinuations that tend to reflect upon our loyalty and patriotism and we brand our accusers as the instruments of disruption whose aim it is to fan the flame of disloyalty and sow the seeds of dissatisfaction among our ranks. Those who make such charges are in short spreading German propaganda."

John F. McAuley of West Frankfort, Ill., has written to a St. Louis newspaper complaining that the men working at that place have been able to work only 27 days since May 1 and on these days the time of working has been restricted running only two, four or five hours. The last day they were able to work was July 26. The cause of the irregular work is the lack of sufficient electric power to operate machinery. Yet most of the mines could have been working, he says, with or without electricity. "We could shoot our coal from the solid," he adds, "as we did before machinery came into existence and as they are now doing in smaller mines where the companies have not the capital to install machinery. Our mines are equipped with steam hoists. Our fans are run by steam, and at some of the mines mules haul the coal cars. Those who have electric locomotives could have purchased mules and the coal would cost only a few cents more. No changes would be necessary in the haulage road or in any other part of the workings." He concludes by saying that with facts as they are the coal companies cannot avoid the charge that they are slackers.

Some Howat Understudies in Kansas

In August the placidity of the Kansas mining situation was broken and Kansas became Kansas once more. More matters were brought up for adjustment than in any similar period for several months. Fortunately, most of these matters have been settled amicably, and all of those which have been brought up in regular procedure are in process of adjustment.

The first strike for several weeks occurred Aug. 16 at No. 9 mine of the Girard Coal Co., near Pittsburg, Kan. This mine has a long record for strike activity. The demand was for the discharge of a mine foreman. After two days, the men went back to work under orders of the officials of the United Mine Workers; but one day they failed to work, the next they let the mules run away and work had to be suspended, and on the two following days the miners alleged that the air was insufferably bad, although inspectors had approved the condition of the mine.

The miners are back at the Howat tricks. It is wrong to strike and a violation of the contract, but you cannot work if there are no mules or if the air is bad, so if you can arrange the first and plead the second it is quite easy to shut down the mine. Alexander Howat is in Europe, but his understudies apparently are still in Kansas.

Wages Adjusted to Living Costs

A commission was appointed some time ago in Alberta, Canada, to ascertain every four months the change in the cost of living, the wage of the miner being made dependent on their findings. This commission is composed of W. F. McNeill, representing the coal operators; Frank Wheatley, representing the miners of District 18 of the United Mine Workers of America; and F. E. Harrison, representing the Department of Labor. It takes sworn statements regarding the cost of certain necessities and staple commodities and ascertains in like manner the increase in rentals, fuel and light. It has held sittings at Calgary, Lethbridge, Blairmore, Edmonton and Drumheller in Alberta, as well as at Fernie in British Columbia. Prices of commodities were also taken at Nordegg, Mountain Park, Canmore, Bankhead, Coleman, Hillcrest, Pocahontas and Brule. As the last increase was given Apr. 1, the new rate dates from Aug. 1. The schedule of costs is given below.

Commodity	Expenditure per Week Apr. 1	Aug. 1	Change, Per Cent.
Meats	$5.0241	$5.3458	+6.403
Produce	3.9040	3.8538	—1.286
Groceries	6.6560	7.4986	+12.659
Clothing, etc., boots and shoes	5.9579	6.3605	+6.7574
Rent	2.25	2.25	Unchanged
Light	0.50	0.50	Unchanged
Fuel	1.4520	1.4520	Unchanged
Coal bill	0.3208	0.3208	Unchanged
	$26.0648	$27.5813	+5.818

The weekly increase is $1.5165, and that is roughly 25c. per day. This was the increase awarded.

Relationship of Coal to Ships

The Fuel Administration must depend upon ships to supply two great and important sections of our country with coal to keep the people warm and to maintain the constantly increasing industrial activities necessary to the proper prosecution of the war. New England, crowded with great war plants which are turning out a multiplicity of material for our army and navy, must be supplied to a large extent by ocean shipments from southern tidewater ports. The overburdened railways cannot carry more than approximately one-third of New England's coal supply for the year. The remainder demands ships. Without them the wheels of New England's war industries must stop, and New England's people must suffer.

The great section of our country at the northern end of the Great Lakes must likewise depend upon shipping for its coal supply. A great fleet of coal-carrying vessels must be in constant service from the lower lake ports to the great coal docks of Lake Superior and Lake Michigan, throughout the open season, if the great Northwest is to secure its winter coal supply. The enormous tonnage of coal demanded by this section cannot be imposed upon the already overburdened railroads. It must move by water and it must move while the Great Lakes are open for navigation.

All of this means ships, and as the program of the Shipping Board continues to be worked out, ships, sufficient to carry the coal supply, become available. Today ships are available to move the constantly increasing coal production. But railroads, ships and coal must grow together in order that a coördinate machinery may be always at hand to keep the nation supplied with fuel.

Fuel is a vital factor in maintaining the nation's shipbuilding and in moving the nation's ships after they are built. As the armies of the United States in France are enlarged, which enlargement is steadily going on, the materials to support them will have to be increased correspondingly. This means more ships to move the commodities of warfare; it means more materials which have to be manufactured; it means increased railroad capacity to forward raw materials and finished products; it means more factories to produce more materials. All of which, depending on ships for the final transportation over three thousand miles of ocean, likewise means more coal.—*Dr. H. A. Garfield, United States Fuel Administrator.*

EDITORIALS

Education and Labor Unrest

MANAGEMENT has taken two views of education. One view is that the workman should know as little as possible and then he will calmly accept what is offered. He will not know any better. The plan really doesn't work so badly till a little light, by some chance, leaks in. Then the trouble begins—the workman, realizing his power but not knowing that it is hedged around by economic limitations, is inclined to demand all that he desires. He believes that the reason he has so little is because he never made a concerted demand before, and it takes some years of social unrest and discomfort to make him realize that a capacity for protest may exist without a power of fulfilling all that the protestant seeks. He has never thought seriously about social affairs, so he has no balance when he does begin to think.

The stablest condition is when every man is thinking and has been trained to think. When a man thoroughly understands how the people around him are thinking and acting, he is quite apt to appraise them and himself with something approaching justice. He is not likely to be hurried into courses which he and everyone else would have reason to regret.

Schools, therefore, that are true schools, that mirror the affairs of the world with a large degree of truth and completeness, are the safeguards of democracy. They assure us of social freedom, but they also in a very real sense give us every protection against social license, and they make it possible for everyone to exercise all the duties of citizenship, which, we take it, is as much to work and produce as to nominate candidates and vote.

Few necessities around the mines are so important as schools, and yet in most cases the payment of teachers is far too low. The teachers in the schools are too often chosen from the families of school directors. As a result they have not had the advantage of an outside environment. They do not mirror the outside world to the scholar, but rather show him the community which the scholar already knows. They are therefore too often narrow in their views and to that narrowness they frequently add the grossest incompetence.

Nothing matters more than the school. It should be taught by bright and intelligent instructors. It should put the seed of thought into the minds of future workers and give them a power for intelligent action in all their future work. There is a great advantage in having a workman who can understand and expand an idea, who can fit in with a new method, who can use a new machine or make a record of performance An educated man is interested in new development and new plans, but an unschooled man who has never been taught that there is anything in life but eating and working has no conception outside of these things. The school should give him new aims and purposes and raise the scholar from the rut of circumstance onto a highway of progress.

But especially are schools needed for foreigners. We complain about their stupidity and disobedience to orders, but we cannot hope that they will understand what we say or rightly evaluate its importance till they can speak our language with facility. They will never enter American life till they learn the native tongue. Every mining village should have its English night school taught by the most competent teacher available, with dumb show, illustration, and a clear enunciation of the sentences taught.

These matters cannot be left to chance. Some employee of the company in every mining town should be elected to the school board and daily agitate for improved conditions—adequate schoolhouses, suitable curricula and competent teachers. An operator is just as much responsible for seeing that he has the right personnel at the mine as that he has the right water in his boilers or the right oil in his cylinders. He cannot get the right kind of employees unless he interests himself in the schools where the coming men are trained. If he cannot look so far, he can at least see that a good school will attract to his mine those persons who have sufficient intelligence to seek a good education for their children. Such persons have doubtless endeavored to secure what education they could for themselves.

Do Mine Workers Drink Too Much?

A QUESTION which has aroused heart burnings throughout the mining regions is whether the mine workers imbibe too freely, and rightly or wrongly every mine worker in the industry immediately and uncompromisingly denies that the mine worker is more intemperate than any one else. After all, is the necessity for an answer imperative? If there is any intemperance, large or small, the result will be decreased production. A little, therefore, is too much. We must rid ourselves of that little by every means in our power, and to aid us in ridding ourselves of it we must appeal to the union leaders for their assistance.

It is no empty flattery to congratulate the mine worker on the sobriety of the men he puts in charge of the union. If the mine workers as a whole were as temperate as their district presidents, vice presidents, secretaries and members of their international board, the question of temperance would never have arisen.

In fact, when the National Coal Association declared for temperance the temperate men in whose hands the mine workers have placed their affairs did nothing to antagonize the movement. It appeared to appeal to them. Some said something that sounded

so like "Aye, Aye," that they were recorded as being entirely in favor of the proposition.

The nonbibulous majority of the mine workers, busy at the mine, engrossed in their work, which is also the work of the nation, had nothing whatever to say. The bibulous, however, always the loudest of talkers, made such a stir that the union leaders were practically obliged to take up the cudgels for the "workingman's beer," whether they so desired or not, and now most of them are lined up on the side which they do not favor. It remains now for the patriot mine worker to assure the union leaders of the strength of the temperate men and to convince them that whether drunkards be few or many, such men are not willing to do their duty as citizens and so need to be restrained by the temperate majority.

The mine workers who believe that the necessities of the war demand national sobriety must not keep their opinion to themselves. It is a belief to be emphasized as strongly as the belief in the importance of buying Liberty Bonds. If men who fail to subscribe to a national loan may be ducked in a pond or ostracized from society, the same may be done to the miner who fails to dig his quota and regards his daily turn as less important than his daily tipple.

Protect Equipment from Lightning

ONE source of considerable needless trouble and loss at coal-mining plants is the injury and burning out of various electrical equipment by lightning. This source of difficulty is most acute and annoying in the spring and early summer. Seldom in the latitude of central and northern United States do violent thunder-storms occur before the vernal equinox, neither are they numerous after the autumnal equinox.

As a general rule, atmospheric electrical disturbances are most numerous between the vernal equinox and the summer solstice, or roughly between April 1 and July 1. On the other hand, such phenomena seldom occur between about December 1 and March 1. The late summer and early fall are by no means devoid of electrical storms, but these storms are as a rule neither as numerous nor as violent electrically as those of the spring and early summer.

The transmission lines from a power plant form excellent conductors for the induction of electrical potential from lightning. As is well known, the phenomenon of lightning is merely the discharge of electric energy of small amperage but extremely high potential from one object or region to another. Thus lightning may flash from one region or locality in the air to another, apparently from cloud to cloud or from a cloud to the earth.

When the difference in potential between two localities is thus relieved by a discharge of lightning, any and probably all conductors in the vicinity are subject to the flow of an induced current. Almost every one has at some time or other received a more or less severe shock from some ordinarily harmless conductor from an induced current of this kind, and other things being equal the longer the conductor the more severe the shock. Thus a stove, particularly if it have a long stovepipe, a line shaft, a wire fence, the eave spouting of a house or a telephone are all well known sources of such shocks. Many a farmer has lost cattle or horses through their being in close proximity to or in contact with a wire fence during a thunder shower.

Various pieces of electrical apparatus such as generators and rotary converters are probably quite as sensitive to such induced currents as are animals or human beings. Suitable protective devices properly installed will protect such equipment from harm, but many operators either do not provide lightning arresters at all, or if they do provide them they permit their installation in so careless a manner as to defeat the purpose for which the arrester is provided.

A large and well known manufacturer of electrical equipment recently wrote *Coal Age* upon this subject in part as follows:

> We are being caused a great deal of extra work, most of it entirely unnecessary, due to the failure of users of electrical machinery to provide proper lightning protection; or, having provided same, to have it properly installed and kept in good condition. During the early spring we sent out a circular letter to a vast number of our customers urging them to install ample lightning protection so that we would not be called upon at all hours of the day and night to perform all kinds of repair work in order to keep up coal production, which was being retarded because of lightning damage to motor-generator sets and direct-current engine-generator sets.
>
> We have no interest whatever in the sale of protective apparatus, but do have use for every minute of our workmen's time without having any of it spent on repair work which could and should be avoided by the proper installation of lightning protection. It is, in fact, a conservation of resources which we wish to secure.

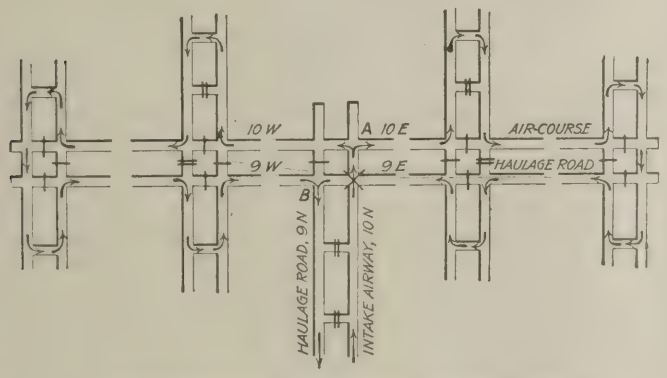
It would appear that no intelligent coal operator would need to be urged to protect his electrical apparatus, any more than he would need to be urged to insure his boilers or place safety valves upon them. Such neglect may or may not result disastrously to the unprotected equipment. The chance for a burnout is present with every thunder shower; the means for adequate protection is comparatively inexpensive, while a mishap of this kind means much more than the cost of repairs. The logical course to pursue would thus appear to be clear and plain. Why not follow it?

Coal Mining and Three-Inch Shells

IT IS sometimes hard to bring people to a realization of the duty which they owe to one another, and to the nation in particular. A case in point is the apathy with which the coal miner has responded to the many efforts made to speed him up, by the urgent pleas on behalf of necessity and patriotism for more regular labor and greater efficiency during working hours. Nothing, perhaps, will aid more in bringing the miner to a full conception of his manifest duty toward the country, at the present time, than the translation of his endeavors into terms of ammunition, ships and supplies. For example, the statement that four shovelfuls of coal mean a three-inch shell for use against the Hun is one that every miner can comprehend—in fact, he can almost visualize shells as he blasts and loads his coal. When all the miners in America begin to dig coal on the basis of so many shells for every mine car full of coal, it won't be long before the Kaiser begins to sue for peace.

He Is Writing To You!

YOUR BOY IS WRITING TO YOU ABOUT HIS GLORIOUS WORK IN THE TRENCHES-FOR YOU. CAN YOU WRITE TO HIM ABOUT THE PATIENT WORK YOU ARE DOING IN THE MINE-FOR HIM; THE TONS OF CLEAN COAL YOU ARE MINING; THE BONDS YOUR WORK IS BUYING; THE SAVING STAMPS THE CHILDREN ARE SAVING AND THE FLAG YOU SALUTE AS YOU GO TO YOUR WORK? BE AS BIG A PATRIOT AS YOUR BOY!



COAL AGE

DISCUSSION BY READERS

Use and Location of Booster Fans

Letter No. 1—Kindly permit me to refer to the question asked by "Mine Superintendent," *Coal Age*, Aug. 8, p. 287, regarding the placing of a booster fan to assist the circulation of air, which has become inadequate, owing to the increased development of the mine. While the answer given to this question appears to be correct, there is room for a little discussion, and I want to ask for a further explanation in regard to the suggested location of the booster "on the return end of the air circulating in that section."

From the description given and the Figs. Nos. 1 and 2, showing the present and the proposed circulations of air, I understand that the prime mover or ventilator is located at the surface and is unable to furnish sufficient air under existing conditions. Now, referring to the proposed circulation, as shown in the second figure, which is repeated here, the main air current is split at

SHOWING THE PROPOSED CIRCULATION

A, being divided equally between the two sections of the mine, and the two currents are again united when they reach the main return airway and haulage road at *B*.

While agreeing with the statement made in the editorial reply and knowing from experience that results will be more satisfactory when a booster is placed at the return end of the air, it is not clear to me how that can be done in the present case, where there are two separate air-courses to be considered.

I assume that it would not be practicable to place the booster on the main return air-course, which is the haulage road in this case. It is possible, however, that the intention is to use two boosters, one in each split. Otherwise, I do not see how it is possible to avoid locating the booster fan in this case on the main intake airway, outby from the split *A*, so as not to interfere with haulage operations.

Permit me to say that my experience is that boosters are a great help located at any point in the circuit. At the same time, I admit that a booster fan located on the intake will increase the leakage through faulty stoppings; but, is it not true that the depression caused by a booster located in the main return airway will produce the same result? I should be glad to be enlightened further and hope to see this question thoroughly discussed, as it is a practical one in the ventilation of mines.

WILLIAM LAWTON.

Seattle, Wash.

This correspondent has offered some very pertinent suggestions in drawing attention to the fact that the wording in the editorial reply to the question, on page 287, inadvertently conveyed the wrong impression and did not express the meaning intended in regard to the proper location of the booster.

The words "on the return end of the air circulating in that section," should have read, *at the inby end of the air current in that section.* It is true that whether the booster is located on the intake or the return airway, in any section of the mine where the circulation is deficient at the face, its action would have the same effect to increase the leakage in poorly built stoppings, since this leakage is determined by the difference of pressure between the intake and return airways. The action of a booster located at the inby end of the air, in any section, however, is to cause a *depression* on the intake and a *compression* on the return airway, in that section, which will result in decreasing the leakage through stoppings. We shall be glad to have this question fully discussed.

Dealing with Slackers in Mines

Letter No. 2—There are many ways in which the half-hearted citizen can dodge his obligations to the Government, but all who do so belong to the same class and can justly be called "slackers." It would seem that fitting punishment, in one form or another, should be dealt to all whose waning patriotism would cause them to be numbered in this class.

In coal mining, the man who loads dirty coal because of neglect, indifference or greed of gain is as much a slacker as the miner who absents himself from his place without excuse, or who fails to put forth his best efforts to increase his daily tonnage. There is no room in the mines, today, for the idler or the careless or indifferent worker.

THE UNSCRUPULOUS SLACKER

The sale of Liberty Bonds and War-Savings Stamps, by the Government, however, has developed another form of slacker, who fills a unique and unscrupulous rôle. This man willingly pledges himself to buy War-Savings Stamps, or signs an application for one or more bonds. In the solicitation for the purchase of bonds he is the acme of generosity. Realizing that the man who can give no reasonable excuse for not buying a bond, either for cash or on the installment plan, will win for himself the name of "slacker," he does not refuse to

pledge himself to purchase untold amounts of stamps and bonds, taking care to parry the question of payment, which down in his heart he has not considered seriously and even has an ill-defined intention of not meeting when due.

Behind this thin badge of dishonor this type of slacker has inspired the faith, praise and admiration of patriotic workers who have devoted much of their time to the solicitation of subscriptions to bonds. Perhaps he can best be compared with the perjurer who, by his false testimony, is the cankerworm to justice in the courts. It is fortunate, at this stage of the war, there are comparatively few of this kind.

Calls for Prompt and Decided Action

In respect to dealing with the slacker, let me say that his little game of evading directly or indirectly the obligations that the war imposes on every citizen should be nipped in the bud, lest the slacker become bolder and his number increase. In my opinion the Government should arouse itself to the full appreciation of the importance of dealing firmly with these men wherever they may be found.

The slacker who fails to meet his obligations in respect to the purchase of War-Savings Stamps and Liberty Bonds should be followed up by an unrelenting and uncompromising collector authorized by the Government to exact the payment pledged. The mine official who canvassed the employees of his company, in the drive, should not cease his service to Uncle Sam until each man has redeemed his pledge. He should keep a delinquent in mind of his deferred payments. It might be better to exact an initial payment of every would-be purchaser of a bond, who would then feel a deeper interest to complete his payments and secure the bond in which he has invested. W. H. Noone.

Thomas, W. Va.

Hindrances to Coal Production

Letter No. 1—I have followed with interest the discussion of the many questions bearing on the production of coal, which is a most vital subject at the present time. Attention has been drawn, by the different writers, to various things that interfere with the regular working of the mines. In the same connection, I want to set forth a few of the hindrances that have impressed themselves on my mind as matters that should be regulated.

In the first place, I want to say that, in my opinion, there is no shortage of mine labor, today, that would warrant the assumption that the mines cannot produce the coal the country demands. I believe a more serious hindrance to coal production is the lack of railroad cars at the mines.

Car supply is a question that the Government must solve if there is to be no coal shortage next winter. Adequate coal production means the prompt loading of cars at the mines. Further, to enable each mine to operate to its full capacity, the cars when loaded must be shipped to market, unloaded, and returned promptly to the mines.

Another hindrance to the work of the miners, which is of quite a different nature, is that presented by the various show attractions, which draw numbers of good miners from their work in the mine. Only the past week a carnival was held in one of the largest towns in this section, with the result that not less than 300 men absented themselves from the mines where they should have been loading 8 and 10 tons of coal apiece each day.

The previous week the mines ran full time and made a record output, while this week all have been forced to run shorthanded, which has greatly reduced the tonnage in this section. The comparison shows the evil effect of permitting frequent shows and other attractions that interfere with the regular working of mines. It would seem to be a matter that should receive the serious consideration of the Fuel Administration.

Referring to the draft and the suggested claims of exemption for coal miners, let me say that I am in the draft myself and expect to be called soon; but another good fellow, perhaps one who is unfit for military service, will take my place in the mine, where he will serve his country as well and as truly as at the front. The call to the colors must consider no one *class* of men as being exempt because they are in that class. The duty of every living soul is to win the war and to serve in the place for which each is best fitted.

Reasons Why There Should Be No Class Exemption for Coal Miners

While exemption for coal miners would affect me, I am not in favor of an order exempting miners as a class. My reason is that there are many men now in the mines who are wholly unfit for and unacquainted with mining work. Under a ruling exempting all coal miners, others would flock to the mines to secure the desired exemption from the draft law.

Let me urge, here, that the administration of the draft should be such that every man will be compelled to answer the call and fill the place where he can best serve. There are men now in the deferred class as being able miners and who, yet, do not work regularly as they should. As a coal miner, I favor any ruling that will assist the work in the mines; but, first of all, I am an American.

Before closing, allow me to mention one other matter observed in this section of our state, which it is to be hoped is not to be found in other states. Here, it has always been the custom for a county assessor to list all the property in the county. This year, the authorities have seen fit, in the interest of economy (?), to cut out the expense of employing an assessor. Every man owning property is compelled to go personally to the county seat and arrange for the assessment of his property and his personal taxes.

The effect of this ruling on the coal production of the county is evident and by no means inconsiderable. A man must absent himself from the mine for a day and possibly two days, in order to go to the county seat and arrange his matters. Others, who are only too willing to avail themselves of any excuse, absent themselves from the mine where they should be loading coal and, perhaps, take much more time to transact their business than would be required if they were more industrious.

The question arises, and may well be asked, whether there is any economy to the country at large, in this

saving to the county the expense of employing an assessor. Again, is the state performing its whole duty to the country by adopting such a system? This, also, is a matter that should receive the attention of the Fuel Administration. I believe the Government should appoint inspectors to investigate not only cases where miners absent themselves from the mines, but such matters as interfere with the working of every mine to its full capacity. OSTEL BULLOCK.

Cleaton, Ky.

The Miner and His Pleasure

Letter No. 2—I have read with deep interest the many letters regarding the miner's relation to the war, particularly the letter of Thomas Hogarth, *Coal Age*, Aug. 15, p. 329, in which he states that the miner "needs all the pleasure he can get." Like Mr. Hogarth, I feel that there is no class of industrial workers who are more entitled to the pleasures of life than the coal miner, so long as he does not allow them to hinder him from attending to his daily work, which is so important at the present time.

It is a pleasure to observe that many mine owners and operators enjoy nothing more than to see their workmen partaking of the same pleasures that are theirs. It is true that, in some districts, there are those who regard the miner and his family as requiring no time for recreation and pleasure. However, these are the exception, rather than the rule. In my opinion, there is nothing more essential to the successful operation of a mine than that the workers shall be given the opportunity to enjoy the pleasures of life. I believe the day has passed when men can be forced to work for a mere living.

It was not long ago that I heard a general manager, in addressing his men at one of their meetings, say that he was proud to see so many of his miners holding $500 Liberty Bonds, and he only wished that he knew how to enable them to buy many more. Expressions of that kind are often the means of tiding a company over a time when labor is scarce. When a company values a man for what he is worth, there is always someone ready to fill the vacancies as they occur, and the ranks of that company are seldom depleted.

COMPARING CONDITIONS IN TWO MINING CAMPS

Compare, for a moment, the conditions in two mining camps, in one of which many of the miners have been able to save a few hundred dollars with which they have bought their homes, and are still laying by something in store for the future. Compare, I say, this condition with that in a camp where hard working miners have been able to lay nothing by, not even enough to educate their children, to say nothing of buying a home.

In the former instance, the children as they grow up stay at home, and the reputation of the place is such as to draw the best class of miners to its vicinity. In the second instance, few of the children, as they become grown, care to remain where their fathers have done so miserably. The place runs down rapidly, and the mines have difficulty in holding their men or securing others to fill the places made vacant by their leaving.

The day is fast passing, I am glad to say, when the mining classes are regarded solely as a means of contributing to the wealth of their employers, and are restricted in their rights to the full enjoyment of life. The cases are rare, now, where the miner is compelled to trade at the company store and to live in a company house, in order to secure the favor of petty bosses and obtain a good working place in the mine and other privileges that it is in the power of the boss to grant.

Welfare work among miners has emphasized the fact that they can and do appreciate the efforts of honest officials in their behalf. Where the miner can take his family out to see some enjoyment after his day's work is completed, he is more satisfied and will do better work the following day for his season of recreation. On the other hand, where no such privileges are at hand who can blame the miner for becoming discouraged, and when in that frame of mind the saloon often proves too strong a temptation for him. The result is that he goes home late and the morning finds him unfitted for his work in the mine.

While these considerations appear to many to be small and of minor importance, they are great and, perhaps, the *greatest* factors in the successful operation of the mines and increasing the production of coal to meet the present demand. Let me say that it is up to all of us, who are a part of the official family of the company who employs us, to make every effort to increase the pleasures and enjoyment of the miner. Let us regard him as on an equality with that of any other industrial worker. By this means will the production of the mine be increased and the living conditions of mine workers be made better. JOSEPH R. THOMAS.

Plymouth, Penn.

Intemperance Hampers Production

Letter No. 1—Referring to the Foreword in *Coal Age*, Aug. 15, p. 297, by R. Dawson Hall, on the subject of intemperance in its relation to the production of coal, permit me to say that while the main issue presented by Mr. Hall cannot be refuted—namely, that many of the miners in the anthracite region are prone to go on a more or less prolonged spree just after every payday—it occurs to me that the greatest harm to the anthracite industry is the steady consumption of poor whiskey and beer, by the *majority*, I might say, of the miners in that region.

While in the vicinity of Scranton, about two weeks ago, I observed some 200 or 300 able-bodied men whose appearance proved that they worked in the mine and who were loitering on the sidewalks, in the vicinity of a number of saloons. Within these saloons and hidden from the observer were, undoubtedly, an equal number of men who should have been at work in the mine.

The particular day in question was not an off day, but one when the mines should have been running at their full capacity if it had not been for the number of men out of their places. The car supply, at the time, was all that could be desired. I cannot say, now, as my recollection does not serve me, whether a payday had just occurred or not; but I know from my observations that these men were the victims of the lure of the occasional drink in the saloon, probably six or eight drinks a day.

While it may prove a difficult proposition to enforce absolute prohibition in the anthracite region, I certainly

agree with Mr. Hall's suggestion, in reference to restricting the hours in which the saloons can ply their deadly trade. It is my opinion that this should be done at the earliest possible moment and that mine operators should get squarely behind their state governments or their county judges and insist, in the cause of humanity, that the hours in which saloons may remain open be greatly reduced.

On the occasion of numerous other trips into the anthracite region, I have observed the same conditions and believe that they must prevail constantly. Medical authorities agree that alcoholic drinks of any kind, whether they contain a large or a small percentage of alcohol, if consumed freely will do more harm to a man than will an occasional debauch.

The result is that the efficiency of the miners, wherever liquor in any form is sold, is severely handicapped. Intemperance on the part of coal miners helps to prolong the period of German atrocities, and every miner, mine official, banker, merchant, clerk and farmer should coöperate to the fullest extent of his ability in getting the Huns and bringing this terrible war to a close.

Philadelphia, Penn. OBSERVER.

The Wagon Mine a Menace

Letter No. 2—Kindly permit me to refer to the letter of H. E. Gray, *Coal Age*, Aug. 8, p. 282, and to say that my experience convinces me that wagon mines are not the menace to the coal industry that Mr. Gray claims. In his letter he likens the enormous growth of smaller mines to that of a "gigantic cancer that is slowly but surely sapping the vitality of the industry." On the contrary, to my mind the growth of the smaller mines is a blessing and should be encouraged, particularly at the present time.

Notwithstanding the fact that every coal miner and operator is being urged, today, to do his utmost to increase the output of coal, and every paper and magazine voices the same sentiment to avoid the shortage in the fuel supply next winter, Mr. Gray would have us close down the small mines. Not only does he charge them with being unsafe and unsanitary, but seems to regard them as the source of the impure coal that has been shipped to market as fuel. Let me remind him, here, that every ton of coal produced, whether from a large or a small mine helps to win the war.

Charged with Shipping Impure Coal and Lack of Sanitation

In regard to the shipment of impure coal, the charge will apply equally to both classes of mines. While it is true that there have been *hundreds* of tons of impure coal dumped on the market, the output of small mines, there have been *thousands* of the same kind of material loaded for market by the large mines. My observation leads me to state that the purity of the output of wagon mines, or "country banks," as they are often called, compares favorably with that of large operations. In the small mine the owner visits every man's working place, each day, and pays particular attention to the loading of clean coal. The miner who is caught loading dirt with his coal is first reprimanded and, if the offense is repeated, he is docked, which is the same penalty as is applied at the larger mines.

Allowing that the equipment for screening and preparing the various sizes of coal is not as complete in the small as in the larger mines, let me ask if the proper sizing of the coal necessarily means cleaner coal. At the country bank the coal coming from the mine is dumped on a platform. Most of this coal is sold for domestic use. The teamster pays close attention to what he loads into his wagon, knowing well that if he takes a load of dirty coal to a customer he will stand a good chance of losing him. This does not apply with the same force to the coal loaded at the larger mines.

In respect to safety and sanitation, I believe that small mines compare favorably with large ones. In the former the ventilation does not have as far to travel and there is generally better air at the working face than in many larger mines where the air current is heavily ladened with smoke and gases. If a person travels a few of the air-courses in many of these larger mines he will be convinced that there is ample room for improvement, both in respect to safety and sanitation.

Again, in the small mine, the miner has less difficulty in securing promptly his needed supplies, which are often brought to him by the next trip into the mine, while in large mines the miner must often wait a day or more and work under bad top until he gets the needed timber to make his place safe. Speaking of safety, it is a fact that miners often leave the larger operations for work in a smaller mine, for reasons of safety only. Reference to the coal report of Illinois will prove that a much larger percentage of accidents happen in the larger than in the smaller mines in that state.

Government Inspection of Small Mines in Illinois

In speaking of Government regulations, Mr. Gray seems to imply that the mining law is not enforced in respect to small mines, which is not the case in Illinois, where the state mine inspectors see that the provisions of the mining law, in respect to ventilation, drainage, shotfiring, etc., are obeyed in large and small mines alike. Old miners often prefer to work in small mines because they are afraid to travel the haulage road in the larger mines, where they must continually seek safety in refuge holes to avoid motor trips.

Finally, another reason for encouraging the smaller mines is that they enable the poor to get coal, when they would be unable to pay the price asked by the middleman or dealer, who must have his profit for handling the product. This is not to say, however, that small operators are cutting the price, which is the same at the small mines as at the large mines; but the output of the former is sold direct to the consumer and escapes the profit made by the middleman.

In closing, let me say that many of our present-day operators would still be digging coal had it not been for the start they got in operating a small mine. I know several such personally who are today among our largest operators. Why then rob the man of limited means of this opportunity to rise and improve his condition?

Moreover, the closing of the small mines would result in hundreds of acres of coal being lost, because the property would not warrant installing a large equipment, or the coal is thin and may lie too far from the railroad to permit of its coming into successful competition with other coal in the same market.

West Frankfort, Ill. GEORGE BOWKER.

INQUIRIES OF GENERAL INTEREST

Improved Coal Equipment

As a student of the University of Southern California, I have been an interested reader of *Coal Age*, which has been helpful to me in my investigation of coal-mining methods and equipment in the United States. At present, I am seeking information in regard to the most improved methods of burning coal, in the production of *power*, and the most up-to-date equipment for loading coal, both in the mine and for shipment. I understand there have been rapid strides made recently in these respects. Unfortunately, I have found there is little information generally available along the lines, which leads me to ask *Coal Age* and its readers the following questions: 1. What are the names of engines that use a powdered coal? 2. What is the most up-to-date coal-loading machine used in this country? 3. Kindly explain the utility of forwarding coal by compressed air.

Los Angeles, Calif. G. HOSOVO.

---

1. This question may refer to an internal-combustion engine, using gas or some form of liquid fuel. The answer to that question is: No attempt to utilize powdered coal as fuel, in an internal-combustion engine, has proved successful, owing to the difficulty of eliminating the ash resulting from the combustion of this fuel in the cylinder.

On the other hand, the question may refer to the railroads that have successfully used powdered coal as fuel for their locomotives. In answer to that question, we would refer the correspondent to the Report of the Committee on Pulverized Coal, as published in the proceedings of the Chicago meeting (1917) of the International Railway Fuel Association. The report of the committee gives a brief résumé of the fuel situation at that time (May, 1917), and emphasizes the growing need of fuel economy. It states that "the burning of pulverized fuel in suspension in the locomotive firebox has passed beyond the experimental stage."

The principal railroads using this fuel in one or more of their locomotives are the following: Delaware & Hudson; New York Central; Chicago & Northwestern; Missouri, Kansas & Texas; and Atchison, Topeka & Santa Fé. This report of the committee to which we have referred was widely discussed by the railroad officials present, and their comments and suggestions afford much valuable information on the subject.

2. A machine has recently been designed by the Jeffrey Manufacturing Co., Columbus, Ohio, for loading coal at the working face in a mine. This machine, which was described in *Coal Age*, July 20, p. 104, is both light and portable and its use has demonstrated the fact that two men can load from 50 to 80 tons of coal in an eight-hour shift, depending on the conditions existing in the mine. In seams where this device can be employed, it will undoubtedly largely increase the tonnage per man. As far as our knowledge goes, this is the only machine designed for this purpose.

In regard to loading coal on the surface, whether in bins, railroad flats, box cars or ships, there are numerous types and kinds of machines employed and it would be difficult to say which of them is the most up-to-date. A loading machine must be always adapted to the particular conditions under which it is required to operate, in order to secure the best results and the highest efficiency. A machine that would give excellent results in the handling and loading of anthracite would, perhaps, prove an absolute failure when employed to load soft coal. It is necessary, therefore, to study carefully both the nature of the material to be loaded and other conditions that must be met.

3. It is difficult to understand to what particular operation in the coal industry this question refers. About 1910 the United States Coal and Coke Co. experimented at one of their mines, Gary, W. Va., with a scheme for transporting coal from the working face to the tipple by what might be styled a "compressed-air system," but which was, in fact, an exhaust or vacuum system.

The scheme contemplated consisted of a pipe line extending from a hopper at the working face, through the mine entries to the surface, where a Root blower was located whose operation produced a strong depression or suction in the pipe line. The coal was mined and broken into fragments by a machine at the face and delivered to the hopper. The suction produced by the blower was such as to draw large lumps of coal through the pipe to the suction head, where the action of gravity separated it from the air and it fell into the chute.

We understand that, later, the same company drove a length of entry that was to be especially adapted to the scheme of transporting coal in this manner to the surface. But thus far there has been no application of the method in practice.

Calculation of Sines, Cosines, Etc.

We are often asked questions, in examination, that require the use of sines, cosines, and tangents. In many cases, the values of these functions are not given, and the candidates are not permitted to bring books or tables to the examination. Can you give me a formula for calculating the natural sine, cosine or tangent, for any given angle? Those whom I have asked seem to be unable to give me a satisfactory answer.

Divernon, Ill. STUDENT.

This question was asked some time since and was answered quite fully in *Coal Age*, Vol. 5, p. 102.

Whenever the answer to a question requires the use of a sine, cosine or tangent, the examining board should either give the required value, or permit candidates to use tables and textbooks. *Coal Age* has always urged that the examination is more practical when candidates have the same access to books in a technical session as they have in practice.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—A gangway is being driven in the Skidmore vein, which has a dividing slate 2 ft. thick; the bottom bench of coal is 3 ft. thick and the top coal 1 ft. thick. How would you proceed with the work in regard to safety? The pitch of the vein is 25 deg.

Ans.—Experience in the mining of this coal and a knowledge of the conditions must alone dictate the safest method to pursue. The general plan to be advised, however, would be to mine a safe distance in the bottom bench of coal which is 3 ft. in thickness. Before doing this, it may be necessary to sprag the dividing slate to give it the needed support while dropping the lower bench of coal. When this coal has been removed, the dividing slate can be dropped by wedging or blasting, after which the upper bench of coal is taken down.

A better knowledge of the character of the underlying and overlying strata will determine whether it will be better to lift bottom on the high side of the gangway or to break the roof on the low side.

Ques.—What safety appliances should be kept and maintained at the surface landings where miners are being lowered into and hoisted out of a mine?

Ans.—Such landing should be protected by safety gates operated by the movement of the cage in the shaft and which are always closed except when the cage is at the landing. The landings should also be protected by safety blocks and derailing switches to prevent cars from running into the shaft. The cage, in addition to automatic safety catches and devices for the prevention of overwinding, should have a hood.

Ques.—In case you should find the water very low in a boiler, what would you do?

Ans.—When the water level in a boiler has fallen below the lower gage-cock, there would be extreme danger in feeding more water into a boiler. At once, throw open the furnace doors and bank the fire, using for that purpose ashes or moist earth, if immediately available. Otherwise, cover the surface of the fire with fresh coal, taking care not to disturb the bed of coals, which would increase the heat of the fire. Avoid disturbing the safety valve, as the sudden escape of steam from the boiler might cause the water remaining in the boiler to vaporize suddenly. Having banked the fire, allow the pressure to drop and the boiler to cool before making any attempt to fill the boiler.

Ques.—Find the piston area of an engine delivering 50 theoretical horsepower, when the stroke is 3 ft. long, the mean effective pressure 30 lb. per sq. in., when the engine is making 30 strokes per minute.

Ans.—50 theoretical horsepower is equivalent to $50 \times 33{,}000 = 1{,}650{,}000$ ft.-lb. per min. Since the length of stroke is 3 ft., and the engine is making 20 strokes per min., the piston speed is $3 \times 20 = 60$ ft. per min.; and the total pressure on the piston, in that case, is $1{,}650{,}000 \div 60 = 27{,}500$ lb. Again, the mean effective pressure in the cylinder being 30 lb. per sq.in., the area of the piston is $27{,}500 \div 30 = 916\frac{2}{3}$ sq.in.

Ques.—Explain fully the essential points in building and erecting mine doors.

Ans.—A mine door should be hung so as to close with the air current and should be given a slight fall so that it will not stand open unless it is propped back or held open. The door should be made of double boards cut on the bias and nailed together firmly to resist sagging. It should be hung in a substantial frame that will not be readily displaced by any ordinary jar. Canvas flaps should be nailed to the edges of the door in such a way as to prevent the leakage of air. Mine doors should never be located at the foot of a grade. Whenever a door requires an attendant, a refuge hole should be cut in the rib to protect him from accident.

Ques.—If you found one split passing more than its share of air, how would you remedy the defect?

Ans.—If a foreman finds the quantity short in one district while another district is receiving more than its requirement, the quantity is regulated by changing the regulator door, or moving the slide in a box regulator, until the desired proportion of air is obtained.

Ques.—When two kinds of powder are used in the same hole, what is likely to be the result?

Ans.—It may be assumed that the two kinds of powder have a different rate of burning, or in other words, one is quicker than the other, in which case the slower powder will be blown from the hole by the explosion of the quicker one. The slower powder being exploded on the air produces a windy shot, which is always dangerous, in coal mining, because of the cloud of dust that it raises. If a second shot follows the first, its flame will be projected into this dust cloud and cause the ignition of the dust, producing a local dust explosion.

Ques.—What conditions make the use of permissible explosives necessary in a mine, and why are they safer than black powder?

Ans.—The generation of gas in considerable quantities at the working face in a mine should make the use of permissible powders advisable if not necessary. Also, such powders should be used in a mine where the coal is highly inflammable and much fine dust is produced. In many mines where these conditions do not prevail, however, a permissible powder will be found to give better results than black powder and should be used because of its greater economy.

Permissible powders are always safer than black powder, in blasting coal, because they produce less flame when exploded. The charge of a permissible powder is limited to $1\frac{1}{2}$ lb., whereby the excessive use of powder by the miner is prevented. When a greater charge is used, th powder ceases to be permissible. A permissible powder is fired by a detonator, thus avoiding the use of fuse or squibs.

COAL AND COKE NEWS

Harrisburg, Penn.

Provost Marshal General Crowder, through Adjutant General Murdock, of the State Department, has overruled the opinion of George R. Stevenson, of Scranton, chairman of the district board covering the anthracite counties, relative to the latter's decision on deferred classification for men employed in and about the coal mines. General Murdock has sent a circular letter to all local draft boards in the matter, in which he quotes abstracts of Stevenson's letter, and does not mince matters in saying that the findings are not correct and that Stevenson has no business anyway in making rulings, that this work is up to the State Department, and that the statements made are "improper" and "unauthorized." Mr. Stevenson resigned his position as Chairman on Aug. 30.

Flotation among coal companies of a loan of almost $1,000,000 to the Luzerne County Gas and Electric Co., and linking together in one huge system of all the electric power-generating plants of the Wyoming coal fields, was planned at a meeting held at Wilkes-Barre on Aug. 28. Present at the session was the head of every coal company from Forest City to Shickshinny, the manager of every power company, public or private, and E. C. Cole, Pennsylvania state director of conservation for the Fuel Administration; G. R. Henderson, administrative engineer of the Fuel Administration, and other engineers connected with the Government.

The meeting, called at the instance of the National Fuel Administration, had the purpose of finding some means of alleviating a power shortage which is being acutely felt in the coal regions. The shortage is made more menacing because at this time it is practically impossible to secure machinery or parts for repairs and enlargements. It is because of this fact that the loan to the Luzerne County Gas and Electric Co., which supplies current for power and light to the greater part of the valley, was projected. This company has the materials either on hand or in course of construction which would make possible a great extension of its capacity. But, like other public utilities the country over, states Mr. Henderson, the Luzerne company finds it practically impossible to secure in the open market the funds necessary for this extension.

The matter of financing the Luzerne County Electric Co., however, remains unsettled, the coal companies showing no great enthusiasm for such investment. A committee of engineers from the various coal companies and the engineers of the electric companies are making an investigation of the entire proposition, and the matter will come up for final settlement at a meeting to be headed by Charles F. Huber, president of the Lehigh and Wilkes-Barre, who will be the spokesman for the coal companies.

Uniontown, Penn.

The program of the Production Department of the Connellsville regional fuel administration calls for a weekly output of 800,000 tons of coal, according to an announcement made by Production Manager W. L. Byers, who is now shaping up details for a "fuel drive" by which it is hoped to increase the region's production the necessary 15 per cent. to realize that goal.

As the opening shot in the production stimulating campaign a message from Charles M. Schwab, director general of the Emergency Fleet Corporation, and one of the dominating figures in the steel and iron trade, was circulated among the coal and coke workers. In that statement Mr. Schwab declared that "the miner who puts in a full day six days in the week is a true patriot and entitled to every credit." He says that "coal miners are doing very necessary and patriotic work, as without coal ships are useless," and that "they should be encouraged, therefore, to strive in every way to produce the maximum tonnage to keep up with the ever-increasing demand."

To pound home to the workers the necessity for full time in the mines and coke yards Production Manager Byers in a statement to the workers in connection with Mr. Schwab's statement declared that "the amount of coal loaded by one miner in one day, if burned in byproduct ovens, will produce enough of the best explosive to charge 160 three-inch shells and make enough coke to produce steel to make 2000 of the shells themselves."

Mild weather and a better car supply worked hand in hand this week with the patriotic coke workers to increase the production, which has dragged for several weeks. The car situation now has been solved, and the region is getting better than an average of 80 per cent. cars. On one day last week the Pennsylvania R. R. placed 100 per cent. cars both for coal and coke loading.

While there was a slight increase in coke production, two holidays and booze consumed following the semi-monthly holiday were factors in preventing a greater increase. The local fuel administration is now working on the liquor problem as it affects the region, but action must necessarily be restricted because of the limited authority on that subject.

Reports are current in both the coal trade and in railroad circles that an order will be issued shortly by Director General McAdoo diverting a goodly portion of coal shipments originating in the Fairmont region from the Baltimore & Ohio R. R. to the lines of the Monongahela R. R. By that arrangement the coal will come down the Monongahela Valley to Fayette City and over the Whitsett Junction branch, connecting with the Western Maryland lines to the seaboard. The advantage of diverting the heavy coal shipments would be to dodge the heavy grades between Uniontown and Morgantown on the Baltimore & Ohio.

Birmingham, Ala.

Despite an improvement in transportation conditions in the Birmingham district the coal output for this section is running short of expectations. Mine-output statistics, however, might be regarded as encouraging, and with better freight-car service from the mines production is expected to show up more satisfactorily.

Coal produced for the past four weeks, according to Government statistics compiled here, is on a basis of 22,000,000 tons a year, which will place 1918 production over that for 1917. The latest official statistics, however, show a most pronounced slump in output. There is a difference of 16,683 tons in the production for the week ending Aug. 17 as compared with the week ending Aug. 10. During the week of Aug. 17 the tonnage totaled 411,035 tons, as against 437,718 tons for the preceding week.

The general situation in the coke field is relatively unchanged, with production at about 90 per cent. of maximum. The coke producers are doing their utmost with the ovens available. All development work in this particular field is being rushed. A casual survey of the general situation, both as regards coal and coke production, shows that in Alabama fuel administration officials are directing production so that the output both at ovens and mines will go to essential industries, to meet the demands of domestic consumers and keep nonessentials from drawing supplies needed elsewhere.

Charleston, W. Va.

Coal production in West Virginia suffered a drop during August because operations were without a supply of cars commensurate to the capacity of the mines. Some districts not heretofore affected suffered from a poor supply, during the last week of the month, the New River District being an instance. There was almost a paralysis in the Kanawha district, where nearly half the mines were shut down, throwing 2800 miners out of work. In other words, 62 out of 132 mines were unable to operate, having no cars. What with a strike in one mine, numerous funerals and the poor car supply, there was mined in the New River district during the week ending Aug. 24, 7548 tons less than during the preceding week; or, in other words, 161,870 tons one week and 169,418 tons the other week. Indifference among miners as to whether they worked or not entailed further losses in the New River district. The percentage of miners not working in some of the mines is running as high as 30 to every 100 miners employed, or approximately 33⅓ per cent. The figures given for production cover the production of 66 out of 71 mines reporting. In the opinion of T. L. Lewis, Secretary of the New River Association, there is room for at least an increase of 20 per cent. in the output without any additional miners being required.

Though contiguous to the New River district, the Winding Gulf district, in the same period that the former region was falling behind, was able to forge ahead in the quantity of coal produced. The increase in the Winding Gulf section amounted to 15 per cent., which is regarded as a most gratifying increase in view of the fact that adjacent districts fell behind.

For the last week or so production has been virtually at a standstill in the Tug River and Pocahontas districts in so far as any increase or decrease is shown. There has been a gain but this was so small as to depress the operators, who know just what could be done under more propitious circumstances. While the car supply showed a decrease of 25 cars, there was on the other hand an increase in the number of hours worked. Miners working 7315 hours produced 437,546 tons. Mine disability resulted in a loss of 6823 tons. In the two districts combined the total production of coke was 43,330 tons for the week.

Cars furnished the Fairmont district during the last week of August were still short of requirements. As 1800 cars on an average are needed to keep all the mines in the district busy, the 1429 cars furnished early in the week were inadequate for all the mines. According to the best information obtainable 7500 more cars could easily have been used last week for loading coal out if these had been placed earlier. Though managing to secure a change in the regulations prohibiting the shipment of coal to New England points in box cars, the team track operators in the Fairmont district are now confronted with another difficulty—they cannot get cars of any description. According to statistics compiled, the Fairmont district needs nearly 1300 more miners.

Though regarded as a part of the Fairmont district, mines in Randolph County and along the Coal & Coke Ry. are not supplied from the cars allotted to that district. The mines in Randolph receive their cars from the Western Maryland, the Western Maryland having taken over the operating of the Belington and Coalton branches of the Coal & Coke.

Dallas, Tex.

Attention of large industrial concerns is being directed to the vast beds of lignite in eastern and northeastern Texas, and many large concerns have already made plans for erecting additions to their plants or instituting the necessary changes for using lignite as fuel instead of coal. Announcement has been made by the United Verde Extension Co. of Jerome, Ariz., that its reverberatory furnaces and boilers of its smelters can be operated successfully and economically by using ordinary lignite in a finely powdered form for fuel, but using this under strong air pressure. The Texas Light and Power Co., which furnishes electric current for numerous cities and towns in all parts of Texas, has stated that it will erect its central power plant on the lignite beds near Rockdale, Texas, from which current will be distributed over high tension lines. These and other developments in Texas at this time point to a greatly increased use of lignite for fuel. There is an unlimited supply of lignite and iron ore in Cass and Bowie Counties, in northeastern Texas, and steps are now being taken toward organizing a company which will erect a furnace and develop the vast iron ore beds, using lignite as fuel. Unlimited deposits of limestone and cement rock can be had from White Cliffs, Ark., 20 miles north of Texarkana, and as the iron ore and lignite beds lie about a like

distance south and southwest of that city, it is proposed to erect the furnace in the vicinity of Texarkana, or nearer the ore beds, so that long hauls may be eliminated.

PENNSYLVANIA

Bituminous

St. Mary's—Owing to car shortage on the Pittsburgh, Shawmut & Northern R.R., approximately 1000 miners are idle and as a consequence the loss in coal tonnage will be in excess of 4000 tons daily. The Pittsburgh, Shawmut & Northern R.R. owns 2500 coal cars, but under the car-pooling system these cars have been diverted to all parts of the country. The Shawmut is not a Government controlled road, and for this reason the operations along its lines are handicapped. The miners and coal operators are much discouraged over conditions.

Uniontown—Development of the Elliott coal field, located along the Monongahela River near Fayette City, has been commenced following the consummation of a $1,000,000 transfer. The tract, for which many prominent operators have endeavored to acquire title, was purchased by Julian Kennedy, of Pittsburgh, and R. C. Crawford, of McKeesport, for a consideration said to be $2500 per acre. Involved in the deal also was the surface of an adjoining farm and right-of-way for a tramroad over several other farms to the river. The development of the tract is being done by the Lowler Gas Coal Co., in which Kennedy and Crawford are reputed to be interested. The plotting of a town has already been laid out and 75 dwellings for the employees will be erected.

Anthracite

Mount Carmel—The Lehigh Valley Coal Co. has completed a new electric washery at Centralia, which will have a daily capacity of 1200 tons.

Hecla—Hecla is a poor place for slackers to hold out in. Seventy-three sympathizers were arrested for attempting to cripple the coke-making business of the village. Four Austrians, who declared they would work only when they felt so disposed, were also arrested.

Mount Carmel—To have been terribly roasted after he had been burned in an explosion of gas was the experience of Joseph Corbett, 43, a miner at the Reading Coal and Iron Co.'s Reliance colliery. Corbett was at work in a breast and ignited a body of gas with a naked lamp. The explosion set fire to his clothing and he was roasted to death. His fellow workmen, Adam Moran, was also badly burned.

Pottsville—The Harleigh-Brookwood Coal Co. has commenced operations for the reconstruction of its coal breaker near Hazleton recently destroyed by fire, with loss estimated at approximately $200,000. The proposed new structure will be of steel construction, to have a capacity of 1000 tons daily. At the present time the company's mines at this point produce about 500 tons per day, and it is said that plans are under consideration for an extensive increase in this output.

Pottsville—Production of coal is not being curtailed in order to force an increase in wages of miners, nor will the miners resort to such unpatriotic devices, declared leaders in this section. The miners declare they feel virtually certain of an increase, and say the only manner in which the coal production will be affected, if an increase of wages is not granted, is that many miners will leave for other occupations.

Hazleton—Announcement is made by the Lehigh Valley Coal Co. that the Buck Mountain workings, which have been abandoned four times as being worked out, are to be reclaimed. It is hoped to obtain thousands of tons of anthracite from the culm dumps.

ALABAMA

Haleyville—The Glen Mary Coal Co. has acquired the extensive coal properties near Delmar, Winston County, owned and operated by Mrs. Mary A. Gamble and sons, comprising approximately 440 acres. It is understood that the new owner is planning for the early operation of the plant.

Birmingham—The Champion Coal Co., recently incorporated with a capital of $20,000, is planning for immediate development work on 600 acres of coal properties acquired in the Boaz district. It is expected to have an initial capacity of about 300 tons daily. W. C. Rust, of Birmingham, is president and manager.

WEST VIRGINIA

Bluefield—In an explosion in a powder magazine owned jointy by the War Creek and Johns Branch Coal companies, two men, whose names could not be secured, were killed last Friday. They attempted to knock the top off a barrel of powder with a pick, while inside the magazine. A spark from the pick set off the power. An explosion followed, the detonation from which could be heard for many miles around.

Whitesville.—The Mordue Collieries Co. is preparing to begin the mining and shipment of coal from the mines it has just opened in the Coalburg seam, where coal will be taken from a 14 ft. seam. The company is under the management of C. L. Allen.

Carbondale—By installing new equipment at Carbondale, where it has acquired the No. 6 plant, the W. P. Price Mining Co., a Dayton concern, expect by the middle of next month to be in a position to ship coal on a large scale.

Ansted.—Operations have been resumed at the Hawk's Nest plant of the Mill Creek Coal Co. which was put out of commission early in the spring by a flood. Then general manager of the company is W. H. Evans, of this place.

Clarksburg—The Mt. Clare Collieries Co. has arranged for motor haulage at its Mt. Clare plant, and at the same time will make other improvements.

The Thermal Coal Co. has extended its operations at Lost Creek by opening another mine there, coal being taken from the Red Stone seam. The company will open two more mines in the same vicinity, where coal will be mined from the Pittsburgh seam. A fan has been installed at the company's No. 2 mine and many dwellings for miners have been erected.

Bazel—In addition to adding many new mine cars to its equipment, the Fort Clark Coal Co., at its plant here, is also installing fans, having driven a 600-ft. airway through the coal. The superintendent of the company is D. F. Gandy.

Fairmont—The old Aurora mine near here has been acquired by Clarence Robinson, of this city, preparatory to resuming operations there. A number of improvements will be made with a view to getting the mine ready to produce a fairly large tonnage, these improvements being made under the direction of Doney Pople. Within a very few weeks Mr. Robinson expects to have the mine in operation.

The reopening of Mine No. 7 of the Jamison Coal Co. this week near this city was rather a noteworthy event in coal circles. Foollowing an explosion two years ago a fire started in the mine, which has been out of commission since then. Sam McMann started the work of reopening the mine and lost his life in doing so. J. C. Davis, ex-chief mine inspector of Ohio, and J. C. McDermott, chief inspector of the Jamison mines in Pennsylvania, were also called into consultation together with W. J. Heatherman, present chief of the West Virginia Department of Mines, who finally gave his approval to the reopening of the mine, delegating District Inspector Regglemen to supervise the work. Two fans—a Robinson and a Clifford—have been installed, and a new ventilating system provided for. An inspection of the mine has revealed that there had been three fires burning after the explosion. Sixty steel cars a day was the capacity of the mine before it was put out of commission.

Elkins—While the West Virginia Coal and Coke Co. expects to open another mine at its Norton operation, above the present mine, the company instead of changing the present siding leading to the mine now in operation, which would necessitate a heavy outlay, will build a tramway from the opening of the new mine to the tipple of the older mine, where the coal will be run over the tipple. The West Virginia Coal and Coke Co. is now loading out on an average of 35 cars of coal a day.

OHIO

Nelsonville—The Standard Coal Co., of which D. F. Shafer is the head, is opening another mine near Nelsonville on the Hocking Valley Ry. It will be the third opening in that immediate vicinity. It is a drift mine into No. 7 seam. The company is now loading 50 tons daily, which will soon be increased to 200 tons. The new mine will develop a tract of 97 acres.

Moxahala—The Roberts Coal Co., Columbus, will soon open a new mine on the Toledo & Ohio Central in a tract of 100 acres, part of which is owned in fee simple and the other controlled by lease. It is No. 6 seam. The work of driving entries has started and a tipple will be erected. It is expected to produce 200 tons daily in about four months. Leo L. Roberts is at the head of the concern.

INDIANA

Sullivan—The residents of Carlisle, Ind., have petitioned the Indiana Public Service Commission to compel the Chicago-Carlisle Coal Co., which operates a mine at Carlisle, to sell coal to the wagon trade there in order to assure a supply of fuel locally for the coming winter.

Terre Haute—Production of coal in the Indiana field for the week ended Aug. 17 was below normal, according to reports made by mine operators to the Federal Fuel Administration. The 204 mines hoisted 399,315 tons as against 638,830 tons the preceding week. The decrease is due chiefly to car shortage. The annual picnic on Saturday also caused a loss of 24,000 tons. The total loss of time because of labor was 3.94, as against 2.38 per cent. the preceding week. The car shortage for the week was 9.23 per cent. as against 8.34 per cent. for the preceding week. The Pennsylvania had the greatest shortage, it being 21.68 per cent. The Chicago & Eastern Illinois had a shortage of 4.83 and the Chicago, Terre Haute & Southeastern of 9.07 per cent. The Monon road had a shortage of only 1.85 per cent. in serving 21 mines.

ILLINOIS

Carlinville—The first coal in the three new mines being opened near here by the Standard Oil Co. was struck recently in Mine No. 4, just north of the city, at a depth of 295 ft. The shaft was started May 1. It is expected that coal will be hoisted about Oct. 1. The hoisting of the first load will be made an event. It will be auctioned for the Red Cross. The three mines will be among the largest in the world, employing several thousand men. The company is erecting large brick office buildings and 250 one-story houses for the miners. Its power plant at Shoper will have capacity for all the requirements of the three mines and more.

Marion—A new coal-mining town being established by the Old Ben Corporation on the border of Franklin and Williamson Counties is to be named Pershing. The company is sinking a shaft for a new 5000-ton mine. It is expected that the vein, 420 ft. down, will be reached and coal hoisted by Dec. 1. Eighty acres has been purchased for the town site.

West Frankfort—Mines Nos. 18 and 19 of the Peabody Coal Co. will soon be equipped with individual electrical units. At Mine No. 19 a 450-kw. generator will be installed, to be connected with Corliss engines. Two new boilers will also be installed. Automatic hoisting cages were installed in this mine during the lull in business this summer. Mine No. 18 will be equipped with the same or a larger generator than Mine No. 19.

Galesburg—B. F. Stanforth has purchased the Davis coal mine from Jesse Hillier, who has been conducting it since 1904.

Duquoin—Evan D. John, Director of Mines and Mining, has announced that an examination for state mine inspector, mine manager, hoisting engineer and mine inspector will be held at Springfield Sept. 10. All applicants for state mine inspector and first-class mine manager must have completed a course in first-aid work at a mine-rescue station.

KENTUCKY

Louisa—The Louisa, Fort Gay Torchlight Coal and Development Co. plans coal land developments at the mouth of Lick Creek, near here. This company was recently organized with C. E. Stafford as president. Its plans provide for opening 10 collieries, building a central power plant and constructing a 10-mile railway.

Whitesburg—The Elkhorn & Jellico Coal Co., recently incorporated with a capital of $500,000, is planning to commence operations at an early date on the development of about 550 acres of coal properties recently leased. The company is planning for the immediate installation of the necessary equipment. M. K. Marlow is president and manager.

Henderson—The Hayes Coal Co. is opening a new mine at Zion, and has fired its first shots. The shaft is 120 ft. deep. The mine so far has proved very dry. The company will build a tipple at once and install equipment to facilitate handling.

OKLAHOMA

Tulsa—J. A. Brantley, of Sand Springs, Okla., expects to start the opening of a coal mine near here some time during the month of September.

Foreign News

Tokio, Japan—Serious disturbances are reported among the miners in the Kyushu coal district. At one colliery the miners set fire to the mine buildings. Fifty houses were destroyed.

Ottawa—The Lignite Utilization Board, which will have charge of the establishment and operation of the plant to be constructed in Saskatchewan for the carbonization and briqueting of lignite coal to produce a domestic fuel, has been appointed. It comprises R. A. Ross, consulting engineer, of Montreal, chairman; J. M. Leamy, of Winnipeg, Man., provincial electrician; and J. A. Sheppard, a leading business man of Moose Jaw, Sask. The cost of the plant is estimated at $400,000, of which the Canadian government will furnish $200,000; Saskatchewan, $100,000; and Manitoba $100,000. The recovery of oil, pitch, ammonia, etc., as byproducts will be an important feature of the undertaking.

Personals

W. J. Freeman, of Terre Haute, Ind., president of the Indiana Coal Operators' Association, and president of the Green Valley Coal Co., has been appointed coal production manager for the Indiana coal district by James B. Neale, director of production for the Federal Fuel Administration at Washington. Mr. Freeman is also a member of the Indiana State Council of Defense.

Coming Meetings

New York State Coal Merchants Association will hold its annual convention Sept. 5-8 at Saratoga, N. Y. Secretary, L. V. Shepard, Elmira, N. Y.

Indiana Retail Coal Merchants Association will hold its annual convention Sept. 25 and 26 at Hotel Severin, Indianapolis, Ind. Secretary, R. R. Yeagley, Logansport, Ind.

National Safety Council will hold its seventh annual safety congress Sept. 16-20 at Hotel Statler, St. Louis, Mo. Secretary, W. H. Cameron, Continental & Commercial Bank Building, Chicago, Ill.

Publications Received

Fuel Facts. United States Fuel Administration, Washington, D. C. Unillustrated, 64 pp.; 6 x 9 inches.

Report of British Columbia Minister of Mines, 1917. Printed by authority of the Legislative Assembly. Illustrated; 557 pp.; 7½ x 10½ inches.

The Diffusion of Oxygen Through Stored Coal. By S. H. Katz, Department of the Interior; Bureau of Mines. Technical paper 170. Illustrated; 44 pp.; 6 x 9 inches.

Monthly Statement of Coal Mine Fatalities in the United States, April, 1918. Compiled by Albert H. Fay. Department of the Interior: Bureau of Mines. Unillustrated; 21 pp.; 6 x 9 inches.

Analyses of Canadian Fuels; In Five Parts; Part I—The Maritime Provinces. Compiled by Edgar Stansfield, M. Sc., and J. H. H. Nicolls, M. Sc. Bulletin No. 22. Canada: Department of Mines. Unillustrated; 28 pp.; 6½ x 9½ inches.

Trade Catalogs

McGraw-Hill Books. McGraw-Hill Book Co., Inc., 239 W. 39th St., New York. Catalog. Pp. 226; 5¼ x 8¼. This catalog is classified by subjects, is indexed by authors, titles and subjects, and lists the McGraw-Hill engineering, scientific and business books.

Williams Digging Buckets. The G. H. Williams Co., Erie, Penn. Catalog. Pp. 48; 5¼ x 7¾; illustrated. Lists the Williams clam shell buckets and material handling machinery. Accompanied by a separate data supplement.

Vertical Triplex Power Pumps. Worthington Pump and Machinery Corporation, 115 Broadway, N. Y. Bulletin D-702. Pp. 56; 6 x 9 in.; illustrated. Gives a clear insight into the details of the construction of the Deane of Holyoke triplex power pumps, single and double acting.

Magnet-Operated Brakes for Direct-Current Service. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Booklet G. Pp. 4; 8½ x 11 in.; illustrated. Makes mention of the operating features of these brakes. Ratings, dimensions, engineering data and the formula for determining the retarding torque required for any brake installation are given.

Westinghouse Instruments and Relays. Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn. Catalog 3-B. Pp. 103; 8½ x 11; illustrated. A departure from the original edition of the same catalog, in that wherever possible each particular type of apparatus is listed on only one page. Where more than one page is required, the several pages necessary are confined to a description and listing of only the one particular type—so that it is very easy to find what one is looking for in this catalog.

Industrial News

Chattanooga, Tenn.—The Such Creek Coal Co. has filed notice of an increase in its capitalization from $50,000 to $200,000, to provide for business extensions.

New York, N. Y.—The Scranton & Wyoming Coal Co., Inc., East River and Thirtieth St., has filed notice of an increase in its capitalization from $100,000 to $190,000, to provide for business extensions.

Washington, D. C.—An examination of the business records of about 265 coal producing companies by experts of the Internal Revenue Bureau has disclosed unreported profits yielding more than $5,000,000 additional tax revenue to the Government.

Providence, Ky.—L. Sornborger & Co. have taken over the mines of the Washington Coal Co. L. Sornborger will be general manager, and Joe Jennings will continue as superintendent. The new company plans enlargement of its capacity and additional holdings.

Curtis Bay, Md.—The Baltimore & Ohio R.R. has awarded a contract to the Surety Engineering Co., 30 Church St., New York, for the construction of a new one-story reinforced-concrete and steel addition to its local coal-thawing plant, to provide for increased operations.

Chicago, Ill.—The Chicago Great Western Railroad Co., West Harrison St., has awarded a contract to the Railroad Water and Coal Handling Co., 608 South Dearborn St., Chicago, for the construction of a new coaling station at Kansas City, Mo., to have a capacity of 100 tons. The estimated cost of the structure is $20,000.

Wheeling, W. Va.—The Hall Brothers Coal Co. is a new Ohio County company which has secured a charter authorizing a capital of $50,000, it being the purpose of the company to produce coal in the Northern Pan Handle. The incorporators of the company are John D. Hall, James B. Hall, Henry K. Hall, R. W. Hall and Martha Hall.

Birmingham, Ala.—The Champion Coal Co. has increased its capital from $2000 to $75,000, and will take steps to materially increase the production from Champion mine. W. C. Rust, of Birmingham, is president of the company. Other coal companies incorporated were the Shinbone Valley Mining Co., with a capital of $10,000; Evans Fuel Savings Co., $25,000, and Piedmont Coal Co., $15,000.

Clarksburg, W. Va.—The Baltimore & Ohio R.R. has placed an embargo against box-cars of less than 40 tons capacity going east, and such an order was sent to operators by D. R. Lawson, district representative of the fuel administration for the Fairmont-Clarksburg region. The order makes it plain that box-cars can be shipped into Ohio and points reached by Lake Michigan ferries.

Columbus, Ohio—Ohio operators in the Southern Ohio district have received a circular from W. D. McKinney, representative of the Federal Fuel Administration, urging them to cease the marketing of dirty coal. In the circular it is stated that much dirty coal is still being marketed in Ohio and that the practice should stop at once. It is asserted that some producers are marketing bone coal with the other parts of the vein.

Greenville, Ill.—State's Attorney Meyer, under orders of Attorney-General Brundage, has filed suit in the Bond County Circuit Court against the Mulberry Grove Mining Co., the Smithboro Coal Co., the Bond County Prospecting and Mining Coal Co., the Choctaw Coal and Mining Co., and the Toncars Coal Co., asking that they be dissolved for failure to file annual reports in compliance with the law under which their charters were granted.

Jefferson City, Mo.—State Fuel Administrator Crossley has issued an order that dealers must not supply coal to domestic consumers outside incorporated towns of about fifty counties of Southern and Southwestern Missouri, unless it is shown that the consumers cannot obtain wood for fuel. Local fuel committees are directed to take systematic steps to see that rural domestic fuel consumers supply themselves with wood for the winter's needs.

Toledo, Ohio—Considerable activity prevails in the lake trade as far as the Toledo docks are concerned. During the week ending Aug. 24 the Hocking Valley docks loaded 20,000 tons as compared with 198,000 tons the previous week, making a total of 2,681,411 tons for the season. During the same week the Toledo & Ohio Central docks loaded 90,000 tons as compared with 92,000 tons for the previous week. The total for the season is 1,210,000 tons.

Louisville, Ky.—The City of Louisville has paid the Louisville & Nashville Railroad Co. $7000 for a coal site on Logan St. and will spend $7000 more upon installation of switching facilities for the operation of a municipal coal yard which will supply city buildings, including schools, institutions, etc. The city has already purchased ten cars of coal direct from the mines. It is planned to use the yard in critical periods of the winter to supply coal for domestic use.

Columbus, Ohio—W. D. McKinney, Federal representative for southern Ohio and Mason County, West Virginia, is authority for the statement that 130 mines in the southern Ohio field have secured permits to ship lake coal while 170 have not received such permits. But the number which have not secured permits are generally the smaller mines, and thus the reduction in lake tonnage is not so much as might be expected from a casual examination of the figures.

Milwaukee, Wis.—The Cutler-Hammer Manufacturing Co., manufacturer of electric controlling devices and allied apparatus, announces the opening of a branch office in the Union Trust Building, 15th and H Sts., N. W., Washington, D. C. H. W. Knowles and C. W. Yerger, engineers, who are entirely familiar with the company's products, will be located at this new office. It will be operated entirely for the purpose of giving service to the Government and others having occasion to require information regarding the company's products, orders, contracts, etc.

Louisville, Ky.—Wiley B. Bryan, fuel administrator for Kentucky, has issued notice to the effect that all dealers must fill out triplicate registration blanks, showing extent of their coal business, and general particulars, filing these papers with the administration for reference. Certificates of registration will be issued to all registering dealers, and are to be posted in a conspicuous place. Dealers failing to register will be punished, also jobbers selling to such dealers. The department figures on breaking up the practices of small crooked dealers in this way.

Dallas, Texas—Wiley Blair, Federal Fuel Administrator for Texas, has issued an order directed to 152 Texas counties prohibiting the sale, shipment or distribution of coal for domestic uses within these counties. This order was issued as a means for conserving the coal supply of the state for war purposes, and the 152 counties affected are directed to depend entirely on wood and other fuels for domestic uses. The order was issued after careful investigation made by field agents of the fuel administration disclosed an abundance of wood in these counties that can be used for domestic fuel.

Indianapolis, Ind.—P. H. Penna, secretary-treasurer of the Indiana Bituminous Coal Operators' Association, has made the following statement regarding allegations that Indiana operators were paying bonuses to coal miners: "These assertions are not true. The Indiana Bituminous Coal Operators' Association has for two years been investigating reports that bonuses were being offered or paid, and thus far it has been able to prove conclusively that bonuses were paid in only two instances. It is a fact, however, that the practice of paying bonuses is not generally indulged in in this state and that the number of operators who have been guilty is negligible."

MARKET DEPARTMENT

Weekly Review

Bituminous Production Again Picking Up—Railways in Need of Stimulation—Total Soft Coal Tonnage This Year Ahead of Last Year's Output—Anthracite Shipments Show Increase

DURING the week ended Aug. 24 the production of bituminous coal showed the first improvement in five weeks, due to a slight betterment in the car supply. The output for that week totaled 12,603,000 net tons, and would have been much greater if the car allotment had been regular and the loaded cars had been speeded away from the mines. In fact, the erratic car supply during the month of August was at once the despair of the Federal Fuel Administration—which sees the demand for coal growing larger and larger—and a stumbling block to the operator—who wishes to keep his laboring forces intact and instead finds his men leaving for industries that promise more steady employment.

Attempts to speed up the miner—through the formation of production committees, the holding of patriotic meetings and the other many schemes resorted to by those interested in greater coal production—all go for naught when there is an insufficient number of cars furnished the mines. Without cars the mines cannot work. It is not alone the miners who need stimulating. A little of the energy now expended to boost coal output could profitably be devoted to inciting the railway men to greater efficiency.

However, it should not be overlooked that the production of soft coal so far this year is far ahead of the quantity mined during the same period of last year. If sufficient cars had been placed at the mines there would now be plenty of coal to meet all demands, for even with the handicap of inadequate and irregular labor the operators could have flooded the country with coal.

Anthracite production is not only keeping up, but shows an increase in output for the week ended Aug. 24 with the shipment from the mines of 2,134,000 net tons. The total production of anthracite for the coal year to date is estimated at 41,768,000 net tons, an increase over 1917 of 869,000 net tons.

The Lake trade is active. Under governmental stimulus a larger tonnage is being moved from Ohio and West Virginia to the lower lake ports. Shipments are still behind pre-season estimates, however, and in order to enable the Pittsburgh region to meet its quota coal is being withheld from all nonessential industries in that district, while plants on the preference list which had been receiving only 50 per cent. of their requirements are to be still further reduced. There is strong basis for the feeling that the Northwest will be supplied before the close of navigation.

Market conditions show no radical changes. So much domestic anthracite has already been placed in the bins of consumers that there is little reason to fear a serious shortage in that quarter. Demand is greater than the supply in all grades of coal, with the exception of certain steam sizes on the Atlantic Seaboard and screenings in the Middle West.

COAL PRODUCTION

Recovery from the slump of the past five weeks marked the production of bituminous coal during the week ended Aug. 24. The output during that week (including lignite and coal made into coke) is estimated at 12,603,000 net tons and not only exceeded the production during the week preceding by 669,000 net tons, or 5.6 per cent., but exceeded the production during the past three weeks. Production during the current week of 1918 was 1,852,000 net tons, or 17 per cent. in excess of the production during the corresponding week of 1917. The average production per working day during the week of Aug. 24 is estimated at 2,100,000 net tons, as against 1,989,000 net tons during the week preceding, and 1,792,000 net tons during the week of Aug. 24, 1917.

Production of anthracite in the United States during the week of Aug. 24 is estimated at 2,134,000 net tons, as against 1,924,000 net tons during the week preceding, an increase of 10.9 per cent., and as against 1,988,600 net tons during the corresponding week of 1917, or an increase of 7.3 per cent. The average daily production during the week of Aug. 24 is estimated at 355,667 net tons, as against 336,839 net tons during the coal year to date, and as against 329,831 net tons during the same period of 1917. Total production for the coal year to date is estimated at 41,768,000 net tons, an increase over 1917 of 869,000 net tons, or 2.1 per cent.

Shipments during the week of Aug. 24 increased from all districts with the exception of the district including northeast Kentucky, high volatile and the smokeless fields of West Virginia, and from the Rocky Mountain and Pacific Coast states. Material increases occurred in central Pennsylvania, where shipments increased 3102 carloads or approximately 8 per cent.; in Ohio, where shipments increased 2823 carloads, or 11 per cent.; and in the district including Illinois, Indiana and western Kentucky, where shipments increased 2299 cars or approximately 5 per cent. All districts, with the exception of northeast Kentucky, high volatile of south West Virginia and smokeless fields of West Virginia, report shipments considerably in excess of the performance during the corresponding week of 1917. For the coal year to date all districts, with the exception of Michigan, show increased loading.

Lake Shipments—Bituminous coal loaded on vessels at lake ports (including vessel fuel) during the week ended Aug. 24 is estimated at 1,151,744 net tons, an increase over the week preceding of 3.8 per cent., and over the weekly average during months of July and August of 11.8 per cent.

Shipments of bituminous coal to New England during the week ending Aug. 24 are estimated at 641,592 net tons, an increase over the week preceding of 59,474 net tons, or approximately 10 per cent., and over the weekly average during the coal year to date of 83,000 net tons, or 14.8 per cent. Rail receipts through the New England gateways during the current week increased 25,824 net tons or 13 per cent. over the week preceding, and tidewater shipments increased 33,650 net tons or 8.8 per cent. Shipments also increased from all harbors during the week.

Tidewater Shipments—Shipments of bituminous coal from the North Atlantic harbors and Hampton Roads, during the week ending Aug. 24, amounted to 986,797 net tons, an increase over the week of Aug. 17 of 64,967 net tons or 7 per cent., and over the weekly average for the coal year to date of 89,445 net tons, or an increase of approximately 10 per cent. Shipments from New York and Philadelphia declined slightly during the week, while shipments from Baltimore increased 21 per cent. and from Hampton Roads 12 per cent. Shipments from all harbors, during the current week, were considerably in excess of the weekly average to date.

Beehive Coke—The production of beehive coke in the United States during the week ended Aug. 24 is estimated at 592,000 net tons, as against 575,000 net tons during the week preceding, or an increase of approximately 3 per cent. The average production per working day is estimated at 99,000 net tons, as compared with 96,000 net tons during the week of Aug. 17. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week of Aug. 24 at 402,807 net tons, and operation of their plants at 74.6 per cent. of their present capacity, as against 71.7 per cent. during the week of Aug. 17. Yard labor and car conditions improved slightly during the week.

Byproduct Coke—Operating conditions in the byproduct coke industry improved slightly during the week ended Aug. 24. The plants of the country produced 546,058 net tons, operating at 89.6 per cent. of their present capacity, as compared with 88.3 per cent. during the week preceding. The improvement during the week is attributed by the operators to better labor conditions and to repaired plants. Losses of time due to lack of byproduct coal remained constant at 2.9 per cent. Material increases in production during the week were recorded in Alabama, Maryland, Pennsylvania and Tennessee. In Alabama the improvement was brought about by repairs to plants; in Maryland and Pennsylvania by better labor conditions, and in Tennessee by other causes. The placing of new ovens in operation by the Carnegie Steel Co. at Clairton, Penn., accounts for the increase in capacity in that state during the current week.

BUSINESS OPINIONS

American Wool and Cotton Reporter—Manufacturers are not hurrying to buy cotton at present prices. It is understood that the Government desires for the mills to anticipate their wants up to Apr. 1, 1919, and if possible to make their purchase for that period by Nov. 1. It will be possible to buy the cotton, but the United States Government must of course see that the cotton is shipped, and that seems to be the difficult part of it.

Bradstreet's—The broad tendency is to buy goods only as needs require, there being enough uncertainty ahead to cause chariness. Some sections are more cheerful than others, the South, Northwest and far West being conspicuously optimistic, and even where conservatism prevails, complaints are not serious. In the Southwest, where

drought has struck hardest, the big wheat crop, activity in oil, and vigorous operations in mining afford compensatory advantages.

Dry Goods Economist—Cotton and cotton-goods prices continue to hold the chief interest in all discussions of conditions in the textile world. During the week disturbing reports as to the weather in cotton-growing districts were prevalent in New York, and each new report was followed by new and higher prices for cotton on the New York Cotton Exchange. Because of the high cost of cotton and uncertainty as to the prices that will prevail at the time when the cotton now being contracted for is made up, manufacturers are not seeking future business with the same eagerness as in former seasons. Some, in fact, refused to make any quotations on certain goods this week, while others merely state that "Government prices" will prevail.

The Iron Age.—A swelling of overseas demand, due to the aggressive activities of the Allied forces, has changed greatly the operating schedules of the mills. Urgent calls have been received for rails, rolling stock and shell steel and temporarily some home needs, even cars for our own roads, may have to stand aside. Coming immediately after a heavy distribution of 82 mm. shell bars, an emergency order for 140,000 tons more of this steel, with the same amount to go each month up to February; the allocation of 75,000 tons of rails for France, and the orders now being distributed for 122,500 tons of plates and shapes for new construction in Japan for the Emergency Fleet Corporation, have already made the expected larger purchases of cars for France a matter of the farther future. Rush construction will be given 4000 narrow-gage cars for the Army abroad, following the placing last week of the 20,000 additional 30-ton cars; and many more of these larger size cars are wanted. In order that more ship, shell and rail steel may be turned out, pipe, sheet and wire mills will be cut down further in output. Some wire plants are now on a 50 per cent. basis and may be reduced still further.

Atlantic Seaboard

BOSTON

Awkward situation continues. Fuel authorities are kept busy finding places for coal and still keep within limits imposed by Washington. Belief that ruling is only temporary. Otherwise New England may lose ships that will be vitally needed later on. Hampton Roads piers show average dumping, but delay of 3 to 4 days is usual. Baltimore dispatch somewhat improved. All-rail movement has increased over July figures. Railroad fuel still greatly needed. Rumored that all-rail shipments from Pennsylvania will now be reduced to leave room for increased volume to New York piers. Queried whether pier conditions will admit of much increased tonnage, but coal is needed at points not accessible to steamers. September likely to show important developments. Anthracite rail shipments sag somewhat. New York movement of Reading barges gives no better service as yet.

Bituminous—The state of coal congestion referred to last week continues, although in somewhat modified form. It is very much the result of unequal distribution. If in the first quarter of the coal year there had been normal deliveries instead of arrears to the extent of 2,000,000 tons or more, we should not now have the pressure to unload coal that is a feature in several of the larger New England centers. The car service section of the Railroad Administration is following these instances closely, and every effort is being made to unload both cars and steamers with utmost dispatch. Unfortunately, this all reacts to the disadvantage of New England because at once the impression gains ground that this territory must be stuffed with coal. This certainly is not the fact; it is only our facilities that are congested. Labor is short, repairs are extremely hard to make, never was coal moved from the scales to the consuming territory with the expedition that obtains now. Even the railroads whose reserves are below last year's marks find themselves with much more coal at their terminals waiting to discharge and on cars at their stocking plants than at any time in their history.

It is therefore a condition awkward to handle. The New England Fuel Administration at Boston is doing its best to provide uncongested destinations for the volume of coal now coming forward. This is difficult to do and still comply with the recent ruling from Washington allowing but 60 days' supply for preferred industries. Never before has New England been limited as to the reserves to be taken on during the summer and fall, except purely by the shortage of coal, and there is increasing concern over the situation that this ruling may cease when the winter is upon us. It makes a tremendous difference to consumers in this quarter of the country whether it takes 15 days for a car to come through all-rail from the mines, or whether it takes 45 days.

The stock limits Washington has imposed are so arbitrary, and so out of line with the needs of the case that there is a well-defined feeling here they will be only temporary. State administrators have the right to recommend exemptions in what to them seem special cases. A case like Bangor, Maine, for instance, where the usual channel of supply is by water and navigation closes by Dec. 1, would probably be dealt with in this way. Otherwise, if there are no exemptions, it will soon be physically impossible to load and unload the ships with customary dispatch, and New England would then be in the position of declining the ships that were represented to be so urgently needed last spring. Once the steamers were withdrawn from this trade it would probably be most difficult to secure their return. This territory has had the advantage of continuous service for several months now of two large 12,500-ton colliers belonging to the Panama R. R., but all the time they have been running to Boston there has been but one dock where they could unload satisfactorily. Now as the result of the continuous work at that one plant, day and night, two of the large bridge towers are undergoing repairs, and it will not be possible now to unload either of the colliers mentioned in less than 90 hours, where 25 hours was a normal performance.

Dumping at Hampton Roads has somewhat improved during the past week. Coal is in better volume, and the average detention to bottoms has been reduced. Three to four days is now the usual delay, although the demands for Government service still have a most important bearing. It is understood that the line points and by-product plants are coming in for strong shipments during this month, and it is probable therefore that the movement to tidewater will soon be cut down. It has been allowed to come forward at the present rate longer than was anticipated, but even at that the detention at Hampton Roads would have been more in evidence had there not been a considerable diversion of steamers to Baltimore. At the latter port, through more careful planning, the dispatch has somewhat improved.

The average receipts at the New England gateways during August were nearly 50 cars more per day than during July. The largest part of this extra movement is due doubtless to wagon coal in box cars, the volume of which for New England has continued about 600 cars weekly, or three-fourths of the total number available from central Pennsylvania. Railroad fuel receipts all-rail were slightly less than during July.

One of the interesting facts is that the New England railroads, by several hundred thousand tons, are lacking the stocks on hand they had accumulated by Sept. 1 last year. Were there adequate berth room there is no question but the Boston & Maine and the New Haven between them could absorb whatever extra tonnage may be sent New England the next 30 days, were labor conditions easier and steamers not required to discharge at relatively so few places. The fuel authorities have resumed diverting coal at the gateways to the railroads, and it is probable that an increased movement all-rail for these requirements will be started direct from the mines.

Anthracite—All-rail receipts of domestic sizes fell off during August to a marked degree. The daily average was but 439 cars as compared with 600 during July. The sag has been felt by retailers who are getting increasingly anxious over the small progress made in filling spring orders from householders. The fuel authorities are being asked rather pointed questions as to how to proceed the balance of the season. Coal burning weather will soon be upon us, especially in the Northern section, and it will not be enough to tell consumers they will be served "in turn."

A large number of the Philadelphia & Reading Ry. barges are being sent to Port Reading to load, rather than at Port Richmond as heretofore. This is the result of action by the Railroad Administration, the effort being made to increase the movement of these barges to New England. The difficulty is that the pier facilities are inadequate for all the extra tonnage being thrown in that direction, and it is quite likely that delays in loading will more than offset any gain in movement at sea.

NEW YORK

The anthracite situation not so promising to retail dealers as it was a few weeks back. If coal is available they will concentrate efforts on small orders this month. Producers put winter prices into effect. Dumpings at the local docks fall off for both anthracite and bituminous. Manufacturers kick at maximum storage order from Washington. Public service corporations may be hard hit.

Anthracite—The situation does not look so promising as it did two weeks ago. Coal is not moving as freely and the dealers, now that September is here, are worried over the prospects. In their efforts to aid the consumer as much as possible, plans are under way to concentrate work on delivery of the one and two ton orders now on the dealers' book. Dealers are only waiting assurances from the Fuel Administration that they will get the coal, and then they will go ahead with their plans, which in part include the setting aside of one week for the delivering of these small orders.

The producers and shippers are now receiving the full winter prices for the domestic sizes of anthracite, the 30c. per ton which was deducted by Dr. Garfield on Apr. 1, from the prices for egg, stove, nut and pea having been automatically restored on Sept. 1.

The heavy production figures issued by the producing interests are not borne out by the cars dumped at the local docks during the seven days ending Aug. 30, as compared with the previous week. Reports show 7188 cars dumped as against 7616 cars, a falling off of 428 cars. For the month of August, lacking the last day, there were 31,321 cars dumped, compared with 31,284 cars dumped in July and 30,719 cars dumped in June.

The dealers in the Bronx have had a conference with representatives of State Fuel Administrator Cooke and have been assured of an increase in their tonnage of 13 per cent. over the 1916-1917 allotment. The allotment for the county is figured as 850,975 tons, while the total receipts during the current coal year—Apr. 1 to Aug. 24—have been 257,646 tons, or about 30 per cent. of the total. In order to prevent a serious situation it is claimed by the dealers it will be necessary that an average of 3297 tons daily must be received there for the next 180 days of the coal year.

Dealers throughout the city continue to call attention to the vast number of unfilled orders, but admit that the majority of these would not have been received so far in advance were it not for the urgency of the authorities. There is more coal in the house bins at this season of the year then probably ever before, and in that respect the consumer is much better off. However, many inland yards are entirely clear of supplies while others are said to have good stocks.

The movement at the docks is free. Not much delay is occasioned in loading, with boats plentiful although carrying charges are stiff. As has been the case for a couple of weeks, chestnut is running easier than either egg, stove or pea coals. The steam coals are easy. Some retail dealers have so much rice and barley on hand that they are letting the public know about it through advertising in the daily papers. Buckwheat is in good demand but there is no rush in buying.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea..... 5.50	6.25		

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous — Conditions in the bituminous situation are not so encouraging as the trade would like them. Receipts do not increase in keeping with the demand, due in most part to enlarged consumption by war and other industries which is more than likely to increase now that fall and winter is upon us.

The new fuel ruling fixing maximum limits for storing bituminous coals has not pleased everybody, and some manufacturers near New York claim it will cause hardship. Public service corporations will be hard hit, and already steps are being taken to have the order modified.

The falling off in production is accentuated in the number of cars dumped at the local docks during the week ending Aug.

30, the reports showing 6582 cars dumped as against 7091 cars the previous week. For the first 30 days of the month 30,126 cars were dumped as compared with 30,372 cars in July and 31,129 cars in June.

There has been a good movement of commercial coals and regulars are getting all they need for current uses, with some left over for stocking. In certain instances shippers have been instructed to stop shipments to non-essential industries and to concentrate their shipments to plants on the preferred lists. Coals for the spot buyer are just as scarce as ever, and there is little to be had.

Bunkering continues to be heavy, with plenty of coal for the purpose to be had.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack.....	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine.....	3.08	5.23
Prepared.....	3.36	5.51
Slack.....	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite situation gives indication of improvement. Increased allotment to be made now. Retail labor shortage coming. All sizes active, with stove in strongest demand. Preparation is good. Steam sizes fully taken. Bituminous shortage still exists.

Anthracite—As fall approaches we are becoming convinced that this city will avoid many of the anticipated coal troubles. Each week the feeling of optimism grows among the larger buyers. At the office of the largest shipping company the same confidence is expressed and the reason given is that they will have a substantial tonnage to distribute on account of the prohibition of shipments to numerous points formerly supplied with anthracite. While many complaints continue to come in most of them are from small communities where a few thousand, or even a few hundred tons, will fulfill the shipper's obligations.

Locally the shipments were quite heavy during the last half of the month, and a number of dealers have fair stocks because they were unable to deliver the coal as rapidly as it came in. Yet even with this condition we are safe in saying that the city has not reached the quota allotted to it, and that is one reason why the dealers are expecting particularly heavy shipments during the early fall.

The increased allotment of 18 per cent. to the state was only officially announced recently, and now the increased proportions to each community are awaited with more than ordinary interest. These figures have been decided upon by the Anthracite Committee on Distribution and in many instances are known, but until each shipper is notified as to his quota they are not considered official. There are some shippers who will be unable to furnish any substantially increased tonnages to their trade for the reason they have already been called upon to accept business not formerly cared for by them.

The advance of the wholesale circular on domestic sizes provoked quite a little discussion before it was officially announced. Of course, the advance of 30c. at this time was fixed last spring by the national authorities, but during the past week there was a persistent rumor that the increase was even to be greater than this. To most people, however, this was felt to be purely conjecture, as it was hardly thought that the Government after once fixing the price would take the opportunity to advance it at this time. It seems likely that the rumor has grown out of the fact that the miners are asking for an increased wage schedule. Even though this has been denied by Dr. Garfield, the men still feel confident that their appeal to President Wilson will not be without result. Even in the event of a favorable outcome of their request it was not expected that the new schedule would become effective before the first of the year.

Naturally, just before an advance in prices all family sizes were in great demand, but if there is one size any shorter than the others it is stove coal. Before many weeks the dealers expect to persuade their customers to accept any size they may have on hand, but up till now the buyer of family coal insists on having what he is used to burning. This is the cause of much complaint to the dealers whose trade is not familiar with conditions.

Once more the dealers have been urged by outside organizations to expedite unloading of coal. There is hardly any question that the anthracite trade releases railway equipment about as promptly as any industry. The latest plan is to have them unload on Sunday, which many of them have done for months. However, it is planned to have a force of laborers go from yard to yard on that day and thus effect an economy in labor and at the same time release cars promptly. So far as can be learned the dealers are willing to cooperate in the movement.

The question of preparation came to the fore recently due to the fact that several cars of river coal were condemned in the region for containing at least 50 per cent. foreign matter, such as stones and dirt. On the average, however, the production of both colliery and washery coal is well up to the average of preparation and there can be no real complaint on this score. The double check inspection is still effective in the region whereby inspectors of the Fuel Administration pass upon the coal after the colliery inspectors examine it.

There is no change of any moment in the steam trade. Buckwheat if anything has tightened up a trifle; at least less of this size is coming to the retailers for domestic trade. Barley and rice are also eagerly sought, mostly of course by those concerns who are stocking it for the future. Culm also showed a little increased activity, due probably to the slight decreased shipments of bituminous lately.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—No improvement can be noted in bituminous coal. The mines continue to report a shrinkage of production, due to the unequal car distribution. Nothing that the operators have done seems to make any impress upon the railway authorities as to a change in the method. There does not seem to be any actual lack of cars along the line, it simply being a question of giving them to the mines at the time and in the number in which they are needed.

As a consequence of the somewhat shortened production the distribution committee has started to cut down some plants which have been getting quite heavily stocked ahead. They have taken the stand that many plants with at least a 60-day supply ahead can easily stand having their receipts cut to at least sufficient for current use for a while.

BALTIMORE

Bituminous coal being more evenly distributed as to quantity, but kicks being made as to quality and prices because of box-car shipments. Hard coal men unable to get action so far on price increase and are hard hit by labor deflections.

Bituminous—Under the Government plan limiting coal storage for both essential and nonessential industries, and for all even within the preferred classes, the Maryland fuel administration is now able to make a more equitable distribution of coal here—at least as to amount. It is for the moment not so much a question of supplying coal to a particular consumer who is running low as it is to satisfy him with the kind of coal that is on hand to distribute, and to keep him cool in spite of the fact that his shipment is in many cases in box cars and will cost him around $2 above the ordinary Government price—when the 75c. extra for this coal to operators and the additional costs of unloading per ton are figured.

Some kicks are being made about the quality of the coal received. Much of that coming in box cars, and for which the fancy Government price with additions is paid, is of wretched quality. Some who have received it say that it will not burn at all unless it is mixed with coal of a better quality. The electric power company is still curtailing power, even to war plants, claiming that it cannot get enough coal from the National Fuel Administration, or the quality of coal required to give boiler efficiency. The public service supply was some time since taken out of the hands of the Maryland administrator and the Washington administration undertook to handle the situation direct.

Anthracite—Receipts here continue light despite the fact that there is now reported to be a good flow of coal into the Washington district, so liberal recently, it is understood, that district dealers were unable to handle it promptly and much went into storage in the larger yards. Appeals from the Baltimore section for an increase in movement have not been met as yet. In the meantime dealers find it difficult to keep things going because of labor defections to higher paying Government and war work, which is advertising wages above the coal-yard limit. Despite the fact that dealers have been unable to get action on their appeal for an increase of 20c. a ton in hard coal to cover a wage-increase plan to hold drivers and yard helpers, a number have individually been forced to jump pay rates from 30 to 35c. an hour on a ten-hour day to hold their workers.

Lake Markets

PITTSBURGH

Special attention to byproduct coal. No stocking in district. No open market.

The order of the Federal Fuel Administration upon the distributor of Pittsburgh district coal to curtail shipments to line trade on the preference list to 50 per cent., has just been rescinded. Records of lake shipments for the month of August are not yet available, but it is thought possible that the other districts are doing better so that Pittsburgh need not exceed its quota as much as was expected would be necessary.

The matter of coal for byproduct coke oven continues to receive close attention by the Fuel Administration, it having been made perfectly clear that the chief limiting factor in steel production, or rather the chief factor that can be eliminated, is the supply of coke for blast furnace use, and that depends upon coal supply as there is ample coke-oven capacity. The chief shortage in byproduct coal has been at Youngstown.

The Fuel Administration is considering the starting of Connellsville ovens closed by the Steel Corporation as a result of its inaugurating byproduct coke manufacture at Clairton. The coke produced would be at the disposal of the Fuel Administration, which would be under obligation at the same time to find coal for operating the Clairton plant. It is not known yet whether the proposed arrangements are practicable.

The schedule of quantities of coal that consumers are permitted to stock, expressed in terms of 20, 30 and 45 days' consumption, is not interesting to the Pittsburgh district, seeing that stocking is entirely prohibited in the case of this district, except perhaps of byproduct coal.

There are no open market transactions, all production going out on contracts or being taken by allocations. Maximum prices remain: Slack, $2,10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, brokers being allowed to charge 15c. for brokerage in addition.

BUFFALO

Coal embargoes are disturbing certain classes of consumers. Others found with big stocks are also cut off. General situation not much changed. Anthracite receipts in the city light.

Bituminous—The authorities have been looking into the local coal needs and have made up a list of certain manufacturers who are considered non-essential at the present time. These will have to suspend. All effort is being made to get coal to the farthest outlying districts that are adjudged entitled to it. So much Pittsburgh coal is going to the lakes that shippers here who have always had plenty to distribute are looking elsewhere for a supply.

It is the aim of the authorities to cover all remote all-rail territory as soon as possible. It is said that a coal car can make the round trip to northern New York or New England in about 21 days now, but that it will take 55 days in severe winter weather and that is the reason why Buffalo, which is comparatively near the mines, is getting so little just now of either bituminous or anthracite.

The demand for bituminous is not heavy. If the coal did not go out of its regular territory so much on special orders it would be quite sufficient for all needs. When the lakes close, which will be three months hence, the increased flow to this territory ought to satisfy us, especially since Canada has been cut down in its supply.

Bituminous prices are mostly made up at the mines, but the delivered prices are still $4.65 for thin-vein Allegheny Valley, all sizes: $4.45 for Pittsburgh lump; $4.20 for mine run and slack; $5.60 for smokeless

and smithing; $6.20 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The trade is still much distressed by shortage and certain restrictions and allotments, which do not at all agree with the wishes and apparent needs of the consumers. What they want is the filling of their orders, and some of them cannot see why it is not done. Many of them will accept all the coal they can get, even if it may be, by some mistake or carelessness of the distributor, much more than they need.

Lake shipments have improved again, which may account for the small amount allotted to Buffalo. For the week the loadings for the upper lakes were 119,500 tons, of which 46,200 tons were for Duluth-Superior, 19,300 tons for Fort William, 17,800 tons for Milwaukee, 10,000 tons for Sheboygan, 8900 tons for Chicago, 8000 tons for Racine, 6500 tons for Green Bay, 1600 tons for Depere and 1200 tons for the Sault. Lake freights remain at 48c. to Duluth and Fort Williams, 50c. to Sheboygan and Green Bay, 55c. to Milwaukee, 60-65c. to Chicago, $1 to Racine, Depere and the Sault.

CLEVELAND

Lake shipments of bituminous have been greatly augmented in the last ten days and the movement now is approximating the mark it should have attained by the first of July. The movement in the week ended Aug. 24 was the largest of any week so far this season—1,136,033 tons. Industrial consumers known to have fair stocks or better on hand have been absolutely denied shipments. The retail trade is suffering severely because of concentration on the lake trade, but domestic users are repeatedly promised that their needs will be amply supplied before cold weather sets in.

Bituminous—Announcement that industrial users with fair-sized or better stocks on hand were to be cut off to accelerate the lake movement has been carried out to the letter. Many industrial users claim to be fast approaching the time when their stocks will have to be replenished, but so far not a minute has been lost in any plant because of a shortage of fuel. Retail coal dealers are receiving even less attention than they were a few weeks ago, the whole trend of the coal movement being toward the lake trade.

Labor conditions and the poor car supply have coöperated greatly to reduce output last week in the No. 8 district of southern Ohio. In the week ended Aug. 21, the latest for which the Pittsburgh Vein Operators' Association of Ohio has issued a report, operators belonging to the association forwarded only 4303 carloads of bituminous, divided as follows: 922 cars to railroads, 2367 to the lake trade, 774 to Ohio, 150 to Michigan and Indiana and 90 to Canada. This is only about 70 per cent. of the usual weekly production. Dilatory labor, even more than inadequate car supply, is blamed for this showing. A great many miners now are working only four days a week, operators are complaining, and some go so far as to hint that there may be a connection with the present agitation of the mine workers for increased wages. Car supply for the week ended Aug. 24 to members of the association was 27.86 per cent. short, while in the week ended Aug. 17 it was only 23.08 per cent. short. Though the rating for the week ended Aug. 24 was 8355 cars, the supply was only 6026. The tonnage lost accordingly was 116,450, of which 103,000 tons are blamed directly to car shortage and 13,450 to mine disability, labor shortage, etc. Car supply for the week ended Aug. 24 was 33.49 per cent. short on the Pennsylvania, 28.08 per cent. short on the Baltimore & Ohio, 25.78 per cent. short on the Wheeling & Lake Erie and 11.44 per cent. short on the New York Central.

Lake Trade—The week ended Aug. 24 saw lower lake docks load 1,136,033 tons for the Northwest, a record for the season to date. In the first five days of the week ended Aug. 31 the docks loaded approximately 1,020,500 tons, so the high mark will be approximated, if not exceeded. Supplies are coming forward in better shape than at any time so far this season, due mainly to the restrictions placed upon industrial stocking. High hopes are held that in September, which is only a 3,500,000-ton month on the Federal Fuel Administration's schedule, a gain of about 500,000 tons on the deficit will be possible. The first week of September, however, will do well to show more than 900,000 tons of bituminous loaded, say vesselmen, because of Labor Day and the usual delayed pickup bound to occur on Tuesday and Wednesday of the week. Some coal docks worked Sunday in order to get freighters out of the way. Available tonnage remains all that can be asked.

DETROIT

Shipment of bituminous show a slightly larger proportion of domestic sizes. Receipts of anthracite continue light. Lake movement is still below schedule.

Bituminous—Jobbers and wholesalers in the Detroit market, as well as the consumers of domestic coal, are still taking an apprehensive view of the present situation and future outlook as regards supply of fuel for household heating. While there is said to have been a small improvement in supply of domestic stock within the last few days, the increase in supply is not yet sufficient to relieve uncertainty.

With the short interval remaining in which to provide winter fuel to something like 88 per cent. of the city's population—the proportion which a Board of Commerce investigation discloses is still unsupplied—it is pointed out by jobbers that the movement of coal of domestic type to Detroit must proceed in much larger volume than at present or many families will be obliged to suffer from unheated homes when the frosty weather arrives. There is an impression among some of the operators of large manufacturing plants that unless the outlook for adequate winter fuel supply becomes brighter swiftly, there will be a considerable exodus of workers from Detroit, seeking employment in other cities where there is a better outlook for keeping homes warm during the winter.

The supply of steam coal is fairly satisfactory in volume and seems to meet present needs of consumers, though little is left for adding to stock piles and no free coal is to be found on tracks. Quite a number of the steam plants in previous years have been wholly dependent on track coal for filling their requirements.

Anthracite—Seemingly there is no chance that Detroiters will be able to obtain a larger allotment of anthracite. The city's allowance of 601,000 tons for the year is little more than one-half the quantity actually consumed in Detroit homes last year, and besides suffering this drastic reduction in supply of anthracite the household consumers are also deprived of smokeless and are receiving little coke. Both coke and smokeless have been used extensively in Detroit in past years as substitutes for anthracite. The movement of anthracite into Detroit is small, and jobbers can see no indications of improvement in the near future.

Lake Trade—Shipments of coal by lake routes are not yet coming up to the schedule fixed by shippers. Many boats available for coal cargoes are being sent up light.

COLUMBUS

Special efforts are being made to stimulate production in Ohio in order to avoid coal shortage. A large tonnage is moving via the Lakes to the Northwest. There is also a good demand, both for steam and domestic tonnage.

The feature of the coal trade in Ohio is the effort being made along patriotic lines to stimulate production in every mining field of the state. The lake trade is one of the most active departments of the industry. Under governmental stimulus a larger tonnage is being moved from Ohio and West Virginia mines to the lower lake ports. Reports show that the vessel movement is generally good and that little time is lost at either end of the journey. The lake tonnage is still behind pre-season estimates, but there is a feeling that the Northwest will be supplied before the close of navigation. Lake prices have been affected by the recent reductions announced in Ohio fields. The upper lake docks are generally free from congestion and that is aiding the movement.

The steam trade is strong, although the tonnage available for steam consumers is not large. A considerable amount of screenings is available. Surplus stocks are being called upon to supply factories and public service concerns. Railroads are taking a big tonnage as the freight movement is generally large. On the whole the steam trade is rather active and no one is especially suffering for fuel.

The domestic trade is also strong and some tonnage is available to take care of private users. Retailers are generally short of stocks, however, and strenuous efforts are being made to secure coal. Mine-run is one of the principal grades now delivered. Pocahontas is practically off the market and there is little anthracite available. Retail prices are strong at the new levels occasioned by the reduction in Ohio prices.

Production is rather good and reflects the special pains put forth by interested officials to uphold the output. Car shortage is appearing in some sections, some time before it was expected. There is a shortage of motive power on some of the coal-carrying railroads. In eastern Ohio the output is good and is estimated at 75 to 80 per cent.

Prices on short tons f.o.b. mines are as follows:

	Hocking Thin Vein	Hocking Thick Vein	Pomeroy	Eastern Ohio
Sized grades.....	$3.00	$2.75	$3.00	$2.60
Mine-run.....	2.75	2.50	2.75	2.35
Screenings.....	2.50	2.25	2.50	2.10

CINCINNATI

Inadequate car supply is reported from several districts, cutting down shipments and bringing the Lake movement below the schedule. Otherwise conditions are excellent, including labor.

With reports indicating that the Lake movement is not quite up to the volume scheduled for it by the Fuel Administration, it is evident that the trouble lies principally with the shortage of cars, of which complaints have been numerous and vigorous during the past week. From sections shipping coal into this vicinity—the Kanawha district on the one side and the Knox County district of Indiana on the other—have come assertions that in each case 4000 men are out of work for at least two days a week on account of the inadequacy of the car supply, resulting in a proportionate loss of production. When it is considered that there is a keen demand for labor among manufacturing industries, and that there is also fear of a shortage of labor at coal mines, it can be seen that the car shortage, with its tendency to result in men going elsewhere to work, is serious in more ways than one. There is no apparent remedy possible for the limited car supply, as the Railroad Administration is said to be doing everything in its power to insure an equitable distribution of the cars available, and deliveries of new cars are not progressing with sufficient rapidity to make any appreciable difference. Operators and miners alike are working hard to keep production up to the maximum, but they are of course absolutely limited as to loading by the car supply.

LOUISVILLE

Somewhat better movement of eastern Kentucky mine-run coal to Louisville section. Both western and eastern Kentucky lump scarce. Domestic demand taking care of all receipts of lump coal. Nut and slack showing slight accumulation, consisting of western Kentucky grades.

The situation has shown slight improvement during the past few days. There has been a better car supply in eastern Kentucky, and the western Kentucky supply has been holding up fairly well. Labor has been uncertain, with good supplies one day and poor supplies the next, due to the fact that much part-time farm labor is employed in the mines. However, production in both fields has been somewhat better, with a better movement of eastern Kentucky coal to the lakes, and slightly more coal available for the retailers and jobbers as well as industrial consumers.

The stocking demand continues good, and retailers are still delivering all the lump they can secure without accumulating any yard stocks. A good deal of lump has been going to industrial plants during the past few days, reducing the available supply for domestic stocking. Retailers are fairly well caught up on western Kentucky domestic stocking orders, but are far behind on deliveries of eastern Kentucky coal in cases where people have absolutely refused to accept western.

The steam demand is well taken care of with ample supplies on hand to keep all industrial concerns well supplied. Steam buying has been fairly active, but has not shown near the activity that domestic demand has shown, as industrial concerns are relying on priority needs, and not stocking to any great degree.

No anthracite coal can be sold in Kentucky, but under the regulations Indiana is open to such coal. However, local dealers who have been endeavoring to secure anthracite coal in car lots for deliveries to southern Indiana consumers have been unable to secure supplies, there appearing to be some sort of a mix up in interpretation of the regulations.

Few local retailers are in position to take advantage of the present opportunity to secure eastern Kentucky mine run, not having screens or facilities for sorting the coal, except by hand. Such concerns as have screening plants are managing to secure plenty of coal, and are being offered more business than they can begin to take care of.

BIRMINGHAM

Demand good, but a little easier in steam grades. Domestic sizes strong. Production will probably show some increase over last week, better time being made by mine workers and car supply more liberal.

Reports indicate that steam coal users in some sections have got a little ahead in their supply and are not pushing the mines so strongly for shipments. Inquiries are more than sufficient, however, to take every ton of coal produced at the mines, the output continuing to lag unduly on account of the time being lost by mine workers from their duties, and a slightly crippled car supply.

The domestic market continues brisk, receipts at the yards being about normal with those of the past few weeks. Many unfilled orders are in the hands of the dealers and coal received by them is promptly applied against the business in hand and stocks on the yards are at a low ebb.

Coke

CONNELLSVILLE

More byproduct ovens. Coke supplies fairly adequate. Old screenings advanced.

The Carnegie Steel Co. is now operating about 350 byproduct ovens at the Clairton plant, where the first coke was made late in June. Output, however, is much below rated capacity and partly, it appears, by reason of coal scarcity. Ovens still to be completed at the plant this year will make a total of 640. Present output is a trifle more than 10,000 tons weekly, but full output for the 640 ovens is estimated at about 50,000 tons weekly. The Steel Corporation has recently closed some beehive ovens in the Connellsville region, in connection with its increased byproduct production elsewhere, and the necessity for using the coal in the byproduct ovens. The Fuel Administration now has a project which would involve resuming operations at the closed beehive ovens and would distribute the coke where needed. To put the project through it is necessary for the Fuel Administration to provide a supply of coal for the byproduct ovens, which would be deprived of their present supply from the Connellsville region.

Coke supplies at western Pennsylvania and Ohio blast furnaces are fairly adequate, although there are occasional slight shortages. A considerable tonnage of Connellsville coke continues to be diverted to eastern consumption. There continues to be a good supply of foundry coke offered, and indeed some blast furnaces assert that the operators are offering 72-hour coke for foundry purposes beyond what is needed, and should sell the coke for blast furnace use. Sellers of the best grades of crushed coke recovered from old dumps have advanced their price from $6.50 to $6.75 and state that they have no difficulty in securing the higher price, the material going for household consumption. This is clean prepared coke, over ⅝-in., the official limit being $7.30. Various other descriptions are offered at lower prices. Set prices remain: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ⅜-in., $7.30, per net ton at oven.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Aug. 24 at 337,705 tons, an increase of 11,095 tons. Raw coal shipped out of the region amounted to 214,000 tons, an increase of 24,000 tons.

Buffalo—The demand is always in excess of the supply. This is likely to continue till the war is over. Coke is needed about as much as steel and iron, so that the consumers are able to get together just barely enough to keep in operation. The ovens, byproduct as well as beehive, are coking all the coal they can get, and every effort is being made to increase the capacity of the city coke plants, apparently with the idea that the coal will be forthcoming somehow. Gashouse coke is chiefly used by the gas company to fire its own boilers, and the rule is not to quote it to anybody.

Middle Western

MILWAUKEE

Receipts by lake during August the heaviest of the year. Not much more of the better grades of coal expected, however. Illinois screenings being pressed for use.

The month of August has been prolific in coal receipts at Milwaukee, the record being the highest of any like period since the opening of navigation. With three days to hear from, the total receipts of hard coal for the month aggregate 110,200 tons and of soft coal 684,654 tons. This makes the totals for the season thus far 355,684 tons of hard and 2,040,556 tons of soft coal.

While the foregoing figures have a reassuring influence, State Fuel Administrator Fitzgerald says Wisconsin is much better supplied with coal than any other state and that it is probable not a great deal more of the better grades of coal will be allowed to come here. In view of this prospect, he urges that conservation be practiced in every possible line. Manufacturers are requested to use as large a proportion of Illinois screenings as is possible during the remaining summer and fall months in order to preserve the supply of lump coal for winter use. In the opinion of Mr. Fitzgerald the supply of Hocking and Youghiogheny coal for the West will be cut down because of the necessity for diverting more of it to the East to make up for a shortage in anthracite in that section. In corroboration of this situation he points to the fact that 100,000 tons of screenings from Illinois mines is being shipped to Sandusky, Ohio, by rail and thence by lake to the Canadian Northwest.

Dockmen gave the retail middlemen a rude jolt this week by summarily making an additional cut of 50 per cent. in their allotments of anthracite. This means that many of the smaller dealers will not be able to supply their customers. Many desk-room dealers are being forced out of business by inability to obtain supplies of hard coal.

ST. LOUIS

A continued quiet market with the domestic demand easing up. Very little steam business, excepting railroad orders, which are light, and a surplus of steam coals, with an increasing car shortage. Transportation poor and light country demand.

Conditions continue extremely easy. The retail dealers have at this time no unfilled orders for Standard coal, practically none for Mt. Olive, but the tonnage unfilled for Carterville is greater than they will be able to take care of for the next couple of months. That element of the population that are able to buy storage coal in the summer months seem to have been pretty well taken care of, and it is estimated by the Fuel Committee that 75 per cent. of the residences and homes in St. Louis that could buy coal in the summer time of the Mt. Olive and Standard grade have their coal in.

The retail trade is not pushing orders right now with any undue haste, for fear that later on there will be no business at all and their equipment will be idle. They would rather have a scattered business from this time on rather than have it all now and none later, and that is having some effect on the market.

In the Carterville field the car supply is extremely poor, especially on the Iron Mountain. This road seems to have gone to pieces in the matter of equipment and transportation. The Illinois Central seems to be in the best shape of any for this field.

The operators here are making strenuous efforts to keep their tonnage up, but everything seems to be against them. A good portion of this tonnage still continues to go for railroad purposes, and the output of some small mines is going exclusively for railroad in the form of mine-run. The same condition applies in a general way to the Duquoin field. This territory is in somewhat better shape now as regards water, inasmuch as there have been several rains in the last week or two.

The conditions at the present time in the Mt. Olive field have changed somewhat. Transportation and shortage of cars and the new Illinois draft is the cause of some uneasiness, although miners are supposed to be exempt, but there is a tendency on the part of many miners to enlist in the Navy or the Marines rather than take a chance of not being exempt. In a general way, however, the tonnage from this field is just about equal to the demand.

The Standard field has its ups and downs and some mines have been idle for three days straight on account of no equipment. The Louisville & Nashville seems to have blown up right, and the Illinois Central is in a deplorable shape for equipment.

There has been a surplus of screenings and the operaors have tried to unload as much of their coal in the form of mine-run on railroads as possible; 2-in. lump is not moving well, while the demand for nut and 6-in. is greater than can be taken care of. In a general way, however, there is a surplus in the field of steam coal, and were the market in shape to anywhere near absorb the screenings there would be a surplus of domestic sizes.

There has been no change in the retail prices for some time. They are for all sizes: Carterville, $6.20, Duquoin district, $5.95, Mt. Olive, $5.70, and Standard, $5.45.

The Mt. Olive and Standard prices have been cut, however, to the extent of 50c. a ton in many cases to move the tonnage.

In a wholesale way the Standard market is slightly under the Government maximum. Screenings are around $1.50 to $1.60 and mine-run at about $2.10 to $2.20.

The Government maximum here is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump...	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg..	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut..	2.55@2.70	2.55@2.70	2.35@2.55

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

SEATTLE

Washington mines fall behind in output owing to disastrous fire and shortage of men. Advance in wage scale expected to prevent shipyards taking miners. Large exports being made to South America.

Figures compiled by the state fuel administration disclose the fact that for the month of June the coal mines of the state were 29,000 tons short of their expected production. Of the shortage 16,000 tons was lost by the mines in the Kittitas County district, due in part to the fire at Cle Elum. The fuel administration estimates the state is short 738 miners, and the loss in coal as a result approximates 4800 tons a day. Within a year the draft has taken 320 men and a further loss of 150 is expected in the September call. Many miners are going into war industries and shipyards where the basic pay is higher than in Washington mines. It is expected here that wages will be raised in the state fully 20 per cent., in which case a big increase may be expected in the price of coal. On Jan. 1 of this year there were 5914 men employed in the mines of the state. By June this had dropped to 5250, and today stands at 5176. If the present rate of decrease keeps up there will be less than 5000 men in the mines by Christmas.

The men needed immediately for Washington mines are listed by D. C. Botting, district representative for the Federal Fuel Administrator, as follows: Miners, 528; outside men, 107; inside men, 46; timber men, 15; helpers, 5; timber packers, 8; drivers, 4; rope riders, 1; rock men, 5; track men, 1; coke drawers, 5; motormen, pump men, electricians and other mechanics, 13. The King County district needs 181 men; Kittitas district, 462 men, and Pierce County district, 85 men.

As a means of relieving the pressure upon eastern coal, Washington coals will be tested in South American industrial plants. Heretofore the coal for South American export has been taken from the mines of West Virginia, Pennsylvania and Maryland, but the mines there are now bearing the heaviest burdens in producing coal for Government uses. About 100,000 tons of coal will be shipped from this port during the rest of 1918 to Peru and Chile.

General Statistics

NORFOLK & WESTERN

Below is given a statement of the coal tonnage from mines on the Norfolk & Western R. R. and from other railroads for the month of July, 1918.

From:	Net Tons
Pocahontas field	1,459,618
Tug River district	297,291
Thacker district	283,564
Kenova district	104,374
Clinch Valley district	170,550
Other Norfolk & Western Fields	16,976
Total Norfolk & Western fields	2,332,373
Williamson & Pond Creek R.R.	195,769
Tug River & Kentucky R.R.	62,992
All other railroads	118,752
Grand Total	2,709,886

CURRENT PRICES—MATERIALS & SUPPLIES

IRON AND STEEL

STEEL SHEET PILING—The following price is base per 100 lb. f.o.b. Pittsburgh, with a comparison of a month and a year ago:

Current	One Month Ago	One Year Ago
$4–5	$4–5	$3.60

PIG IRON—Below are the present quotations, with a comparison of a month and a year ago:

	Current	One Month Ago	One Year Ago

STRUCTURAL MATERIAL—The following are the base prices, f.o.b. mill, Pittsburgh, together with the quotations per 100 lb. from warehouses at the places named:

	Mill, Pittsburgh	—New York— Current	One Year Ago	St. Louis	Chicago
Beams, 3 to 15 in.	$3.00	$4.245	$5.25	$4.27	$4.27
Channels, 3 to 15 in.	3.00	4.245	5.25	4.27	4.27
Angles, 3 to 6 in., ¼ in. thick	3.00	4.245	5.25	4.27	4.27
Tees, 3 in. and larger	3.05	4.245	5.30	4.27	4.27
Plates	3.225	4.745	9.00	4.52	4.52

BAR IRON—Prices in cents per pound at cities named are as follows:

Pittsburgh	St. Louis	Denver	Birmingham
3.50	4.24	4.60	4.75

NAILS—Prices per keg from warehouse in cities named:

	Mill Pittsburgh	St. Louis	Denver	Chicago	Birmingham	San Francisco	Dallas
Wire	$3.50	$4.50	$5.05	$4.32	$5.00	$5.95	$4.75
Cut	4.00	5.50	.....	4.47	....	6.40	.....

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots, together with the warehouse prices at the places named:

	Pittsburgh	Cincinnati	Chicago	St. Louis	San Francisco	Birmingham	Denver
Standard railroad spikes ⅝-in. and larger	$3.90	$6.00	$4.50	$5.30	$6.70	$6.00	$5.30
Track bolts	4.90	8.90	5.50	Prem.	8.00	8.25	6.30
Standard section angle bars	3.25	....	4.45	Prem.	5.15	....	6.65

COLD DRAWN STEEL SHAFTING—From warehouse to consumers requiring fair-sized lots, the following discounts hold:

Cincinnati	Cleveland	Chicago	St. Louis	Denver	Birmingham
17½%	List	+10%	+15%	+40%	+30%

HORSE AND MULE SHOES—Warehouse prices per 100 lb. in cities named:

	Mill Pittsburgh	Cincinnati	Chicago	St. Louis	Denver	Birmingham
Straight	$5.75	$7.00	$6.50	$6.25	$8.00	$7.50
Assorted	5.90	7.00	6.50–7.00	6.40	8.25	7.75

Cincinnati—Horseshoe nails sell for $4.50 to $5 per 25-lb. box

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	—New York— Current	1-Month Ago	One Year Ago	Chicago	St. Louis	San Francisco
4 in.	$64.35	$64.35	$68.50	$64.80	$63.00	$80.50
6 in. and over	61.35	61.35	65.50	61.80	60.00	77.50

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	—Pittsburgh— Current	One Year Ago	—Chicago— Current	One Year Ago
Standard Bessemer rails	$57.00	$38.00	$67.00	$38.00
Standard openhearth rails	55.00	40.00	65.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	83.00	*3.135 (100 lb.)	68.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	82.00	*3.09 (100 lb.)	67.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	75.00	*3.00 (100 lb.)	65.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$30.80	$31.00	$34.00
Stove plate	26.20	25.00	19.00
No. 1 machinery cast	34.00	29.50	21.50
Machine shop turnings	16.25	17.00	19.00
Cast borings	16.25	17.10	18.50
Railroad malleable cast	31.20	29.00	25.50

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.19	$0.17½

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	15c.	16c.	15c.
Hollow	24c.	....	....

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Black	Galvanized	Iron Inches	Black	Galvanized

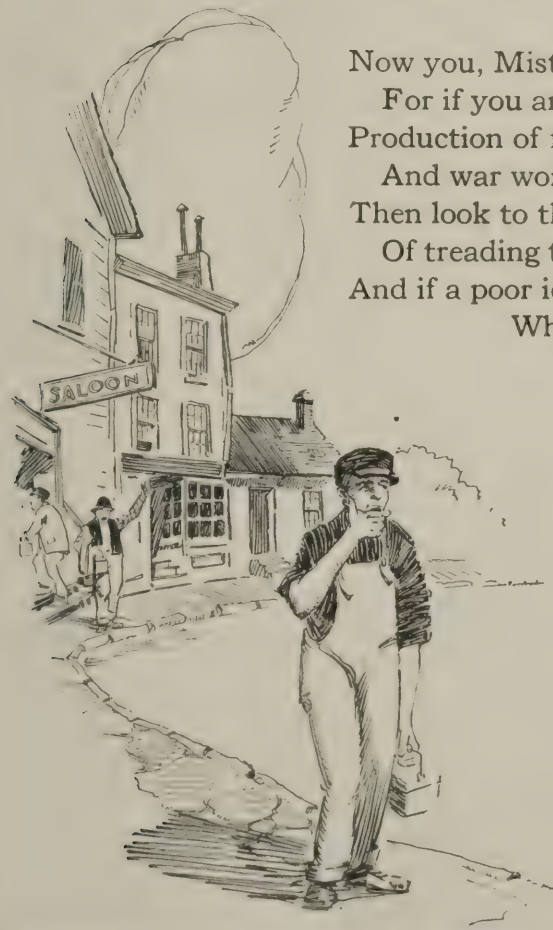
COAL AGE

Volume 14 — New York, September 12, 1918 — Number 11



Think, Man, Think!

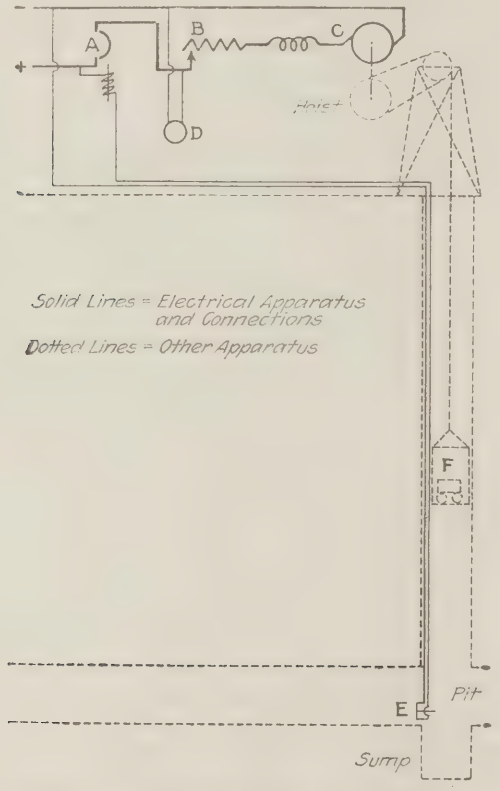
by Rufus T. Strohm

Written Expressly for Coal Age

So keen was the doughboy who went "over there,"
So hell-bent on chasing the Hun out of France,
That Tommy and Poilu were filled with despair
In trying to wean him from taking a chance;
"You're out of the scrap if you're wounded," they said,
"And too many dead put success on the blink;
So stop, when you're tempted to stick up your head,
And think, man, think!"

Now you, Mister Miner, your case is the same,
For if you are injured or if you are killed,
Production of fuel goes halting and lame
And war work's delayed while the job is unfilled;
Then look to the doughboy and learn to beware
Of treading too close to the dangerous brink,
And if a poor idiot flings you a dare,
Why, think, man, think

Fight shy of the perils in practical jokes,
Like jarring a chap with a shot of the "juice,"
For man-power's needed, and sensible folks
May think you're a dangerous fool to run loose;
And if on your way to the work at the mine
Your pals turn aside for a sociable drink,
And urge you to join them at Bacchus's shrine,
Then think, man, think!



IDEAS AND SUGGESTIONS

Safety on an Electric Hoist

By R. J. Calloway
Chicago, Ill.

A large number of the accidents that occur in coal mines arise from careless handling of the cages. I know of three fatalities in a certain Illinois mine due to a misunderstanding of signals between the cager on the bottom and the hoisting engineer on top.

The electric hoist is being used more extensively than ever before, and the safety device proposed in this

ELECTRICAL CONNECTIONS TO THE HOIST

article could be employed quite readily with this type of lift. Manifestly, any scheme tending to promote safety in the handling of cages must place the control of the circuit supplying power in the hands of the cagers themselves. They are the workers who will suffer injury in case the hoist is operated at the wrong time.

The plan suggested may be understood by referring to the accompanying diagram. The hoist in this instance is shown connected to a series motor, although the scheme could be applied to other types. One leg of the circuit runs through the contactor *A*. This contactor should be located in a locked compartment so that it cannot be tampered with. From the contactor the current goes in turn to the controller *B*, the motor *C* and thence to the negative side of the circuit. A pilot lamp *D* is connected across the circuit just ahead of the controller. The control circuit of the contactor is carried down into the pit to the mechanical trip switch *E*.

The operation is as follows: The cage *F*, descending the mine shaft trips out the switch *E* just as it reaches the bottom. This opens the contactor *A*, removing the power from the motor circuit. When the cagers have completed their operations they close switch *E* manually. The contactor *A* then closes automatically, restoring power on the motor circuit and lighting the pilot lamp *D*. The lighting of this lamp is a signal to the operator to hoist. In case the control circuit of the contactor accidentally becomes broken, the power is of course automatically cut off, preventing operation.

Other schemes have been proposed to eliminate the hazards of caging. One plan contemplated loading coal onto the cages at the bottom by gravity much in the same manner as it is removed from the cages at the top. This, however, would in most cases involve a new and expensive form of entry work, and, so far as I am aware, has not been extensively tried out.

"Balance"

By Western Manager

Man at his best in many ways resembles a machine, and like a machine he has a tendency to become erratic under certain circumstances. The human brain acts not only as a storehouse in which should be neatly pigeonholed and ready for instant reference facts gained by personal experience and observation, but as a governor or balance which, when properly operating, should control the conscious actions of the entire mechanism.

Who has not seen an engine damaged or wrecked by the failure of the governor to act during some emergency? Likewise, who has not seen some man's entire future either seriously impaired or rendered absolutely valueless by the failure of his brain, or balancing mechanism, to slow down his actions under excessive internal pressure or outward stress.

The engine governor is constructed to work under a certain maximum pressure, either high or low, and when that maximum is exceeded the governor either slows the engine down or disaster results; and so it seems is the human brain constructed. Some individuals are endowed with high-pressure governing centers which permit of a wide range of control, while others are not so fortunate and seem to have a definite limit, beyond which it is not safe to force them.

Balance is the secret of success; it is known also as horse-sense, and no man without it has ever advanced very far. A man may be highly educated, gifted in his particular line of endeavor, and experienced in the details of his business, but owing to lack of balance he may never advance beyond a subordinate position, while another man, possibly a classmate, who was never noted as a student, may reach the pinnacle of success with no apparent effort. He, however, had balance.

Many a good mine foreman has been spoiled by promotion to a superintendency which he was not mentally attuned to hold. The pressure was too high for his governing faculties, and under the stress he, figuratively, blew up.

Numerous examples could be cited, many of them concrete, of men, who while making an undisputed success in subordinate positions proved egregious failures when promoted, notwithstanding the fact that they may have had the necessary educational training and experience to fit them for the higher position. They were lacking, however, in one essential qualification which sadly cannot be attained by either study or experience.

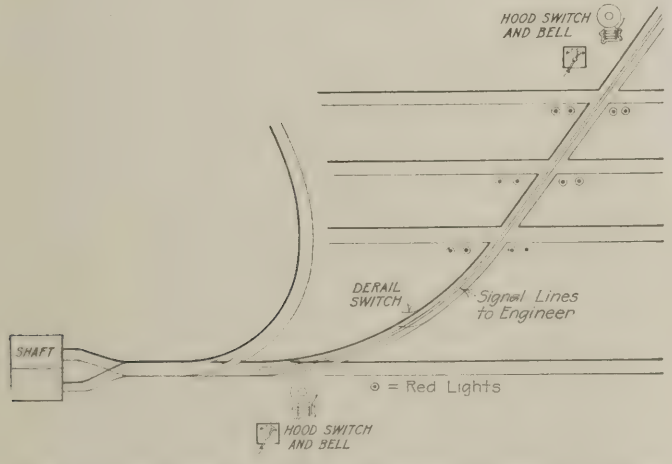
The higher official, when seeking a man to fill a vacancy, is often hard put to find a man having the requisite qualifications of experience, theory and balance, and the last of these is the most unusual. The subordinate who is passed over may feel that he has been treated unjustly, when actually the boss, with his greater experience and wider range of vision, has done him a signal favor by preventing him from making a failure which might affect his whole future.

It is true that numerous individuals, like some engines, run along for years without any obvious balance or control, but sooner or later they reach the scrap heap. The really big men of any industry are those who possess temperaments balanced to the finest point, and with a wide range of adjustment.

Practical Signal System on a Mine Slope

By C. G. Brehm
Oliver, Penn.

In a certain mine the coal is delivered to the shaft, from a higher level, by a dilly trip, on a slope. On the surface there is provided a 150-hp. three-phase, 60-cycle, 440-volt motor, from which a rope descends a borehole and passes around a bull wheel, to pull the empties up the slope to the different landings and



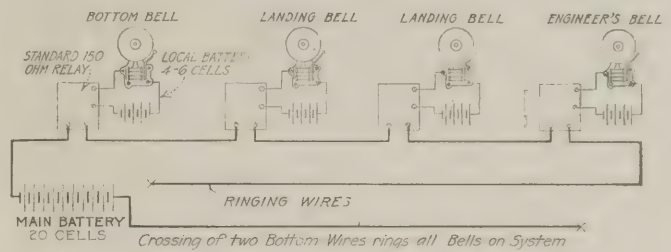


FIG. 1. DIAGRAM OF SAFETY SIGNAL INSTALLATION

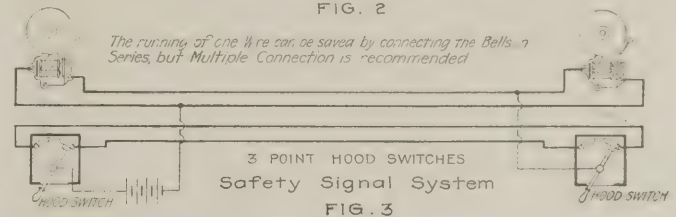
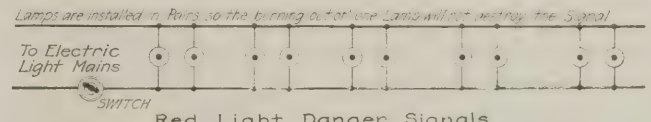
to let the loads down. The length of the haul is about one mile each way, and the loads develop considerable speed in being dropped to the shaft bottom. Throughout the length of the slope is provided a signal line to the engineer. This the rope rider uses for starting and stopping.



Several flats cross this slope, on which drivers are continually working, and as this system was being installed the possibility of accidents on these crossings presented itself. Another danger was also apparent, arising from the possibility of the rope or hitching breaking and allowing the loads to come into the bottom uncontrolled.

In an effort to minimize this danger and also safeguard the drivers at the crossings a system of electric danger lights and signals were installed as shown in Fig. 1. A derail switch was provided on the slope, near the shaft bottom, which normally remains open. On the slope, about 1000 ft. from the bottom, is placed a three-point hood switch and bell connected to a similar



Haulage Signal System

FIG. 2

Safety Signal System

FIG. 3

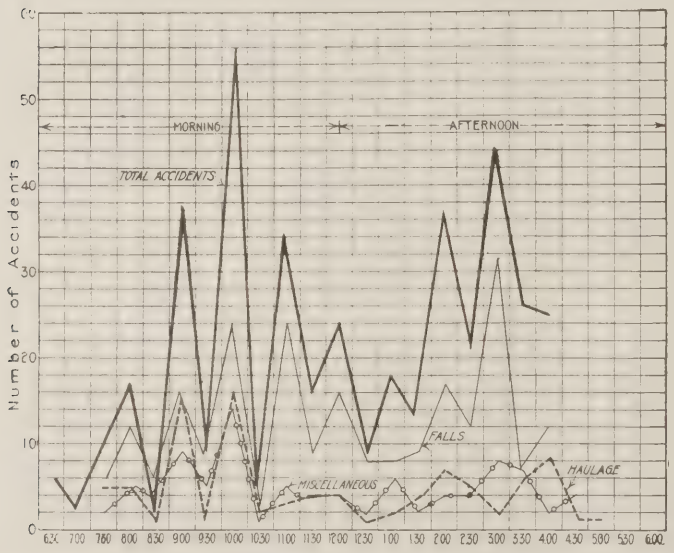
Red Light Danger Signals

FIG. 4

FIGS. 2 TO 4. DETAILS OF THE WIRING SYSTEM

set at the bottom. There is also provided at each crossing red lights, which are lighted by the bottom man when a trip approaches.

The rope rider, on coming down the slope, throws his hood switch, and because of the presence of the bell knows if the bottom man is receiving the signal. In case his bell did not ring he would know that the signals were not working and would stop the trip by signal to the engineer. The hood switch bell on the slope, as well as the one on the bottom, will continue to ring until the bottom man throws his hood switch. The bottom man, upon receiving the signal of an approaching trip from the rope rider, snaps on the red lights for the crossings, closes the derail switch, and the trip is safely landed at the bottom.



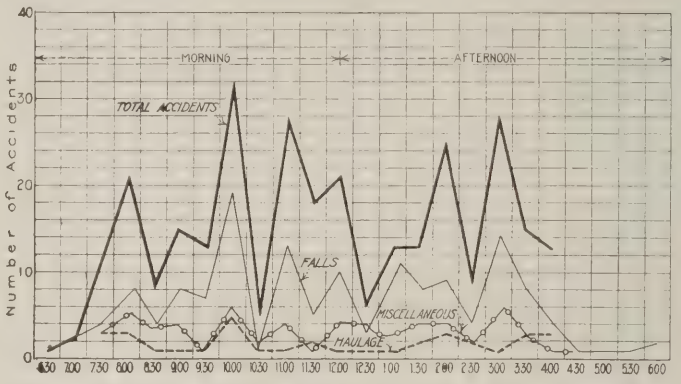
If for any reason, such as the breaking of the rope or hitching, the trip was to run away, a special signal call on the engineer's lines would warn the bottom man and the crossings would be protected by the red lights while the trip would be derailed at the switch. This system has been in operation for several years and has given perfect satisfaction. Details of the wiring are shown in Figs. 2, 3 and 4. No doubt such a signal system, or a modification thereof, can be used to great advantage in many mines.

Who Gets Hurt and When?

SYNOPSIS — Gives details, which have long been desired, relative to the distribution of mine accidents. In the Ellsworth mines Mondays and Tuesdays, ten o'clock and three o'clock, July and August, the third and fourth years of experience and ages over 47 seem to mark points of greatest accident hazard. Most of these dangers could be reduced if appropriate steps were taken by the employee.

THE Ellsworth Collieries Co., of which E. E. Bach is sociological director, not only notes how its men get hurt also when the accidents occur. It further records how long the men have been engaged in mining work and how old they are; in short, it ascertains: Who gets hurt and when?

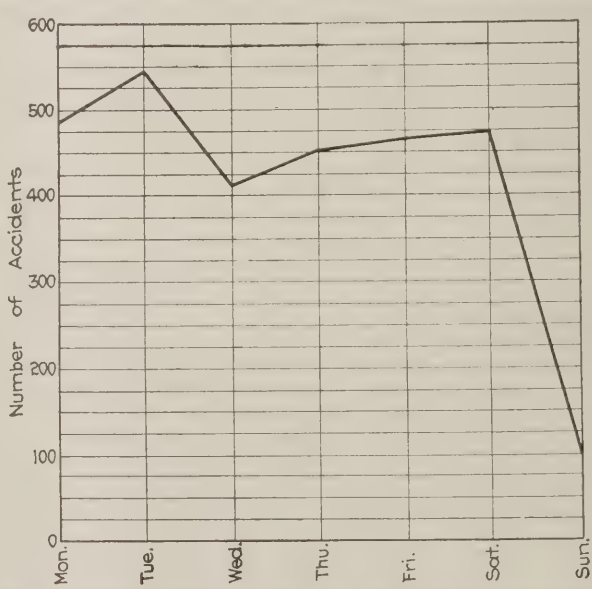
Some people say that men get hurt when they are tired; others say they get hurt when they are sleepy, after long hours, a heavy meal or a midday schooner of ale; some say they are hurt because they drink over much on Saturday and Sunday and do not have full control of their faculties on Monday and Tuesday, and



ELLSWORTH CASUALTIES IN 1916, CHARTED ACCORDING TO HOURS OF OCCURRENCE

so forth. Statistics do not prove much, but they at least give indications which a wise man will heed.

The Ellsworth Collieries Co. has fortunately had an entire freedom from catastrophic accidents since the beginning of its observations in 1911 and before. The figures and charts therefore do not need any revision to eliminate such general accidents. Two charts here presented show the number of accidents in each half hour of the day with reference to falls, haulage and miscellaneous hazards. The charts also show how the total accident rate varies with the half hours of the day. Apparently the early part of the morning is comparatively free from accidents. Ten and three o'clock seem to have been in both 1916 and 1917 the moments of greatest danger. It is natural to ask: Are these the hours of fatigue of the morning and evening? or, "Are there other causes for the frequency of accidents at these hours?"



It is interesting to note that the men are still menaced by rock falls at as late an hour as 3 p.m., for the rate reaches one of its two peaks at that hour. The Ellsworth men must stay perseveringly at their work or the inherent danger of the mine face must be pecu-

ELLSWORTH CASUALTIES IN 1917, CHARTED ACCORDING TO HOURS OF OCCURRENCE

liarly severe at that time. Probably it is the absence of the men from work that accounts for the lower peak in the accident rate at 3 p.m. than at 10 a.m. It is interesting to note that in both 1916 and 1917 the haulage risks were at a minimum at 3 p.m. whereas the miscellaneous risk and the risk from falls was at a high point.

It must be remembered that at these mines shotfirers are employed, but they shoot the coal during working hours, and the progress of shooting may have something to do with the distribution of the accident frequency

ELLSWORTH CASUALTIES, 1911 TO 1917 INCLUSIVE, CHARTED BY DAYS OF WEEK

from falls of coal and roof. It will be noted from a table and a chart accompanying this article that Tuesday is the day with the greatest number of accidents and Monday is the next worst day. One does not know how many men would be killed if the Sunday "drunks" reported for work on Monday, though perhaps this sug-

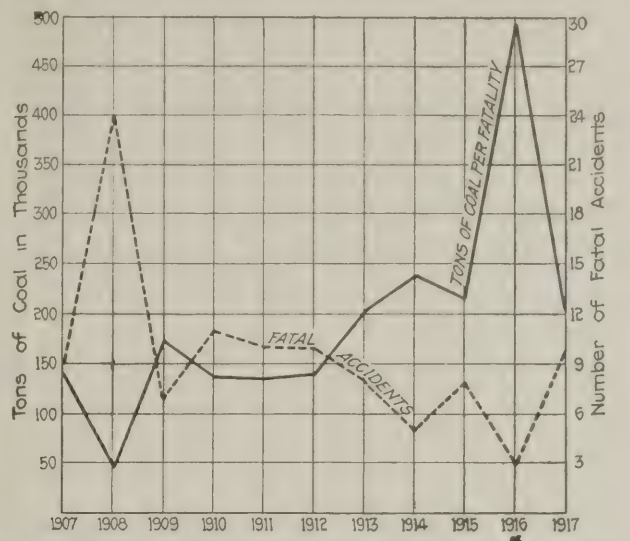
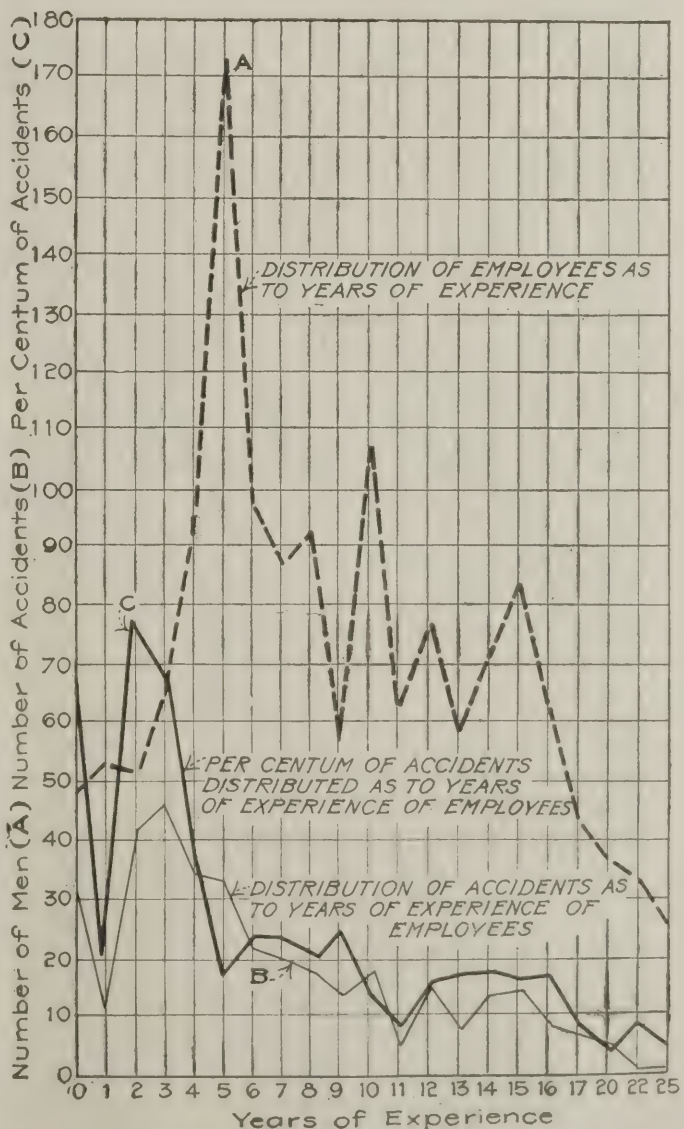
TONS MINED PER FATAL ACCIDENT

Year	Fatal Accidents	Tons Coal Mined	Tons Coal per Fatality
1907	9	1,278,122	142,013
1908	24	1,134,947	48,122
1909	7	1,122,384	174,626
1910	11	1,518,212	138,019
1911	10	1,375,475	137,547
1912	10	1,400,163	140,016
1913	8	1,627,058	203,382
1914	5	1,200,427	240,085
1915	8	1,722,542	215,317
1916	3	1,480,630	493,543
1917	10	2,050,820	205,082

gestion is not fair. It would take a clearer case than is shown to justify the connecting of the larger fatality risk of Tuesday and Monday with the hebdomadal inebriety of mining towns. It may be said that the Ellsworth Collieries Co. village is without a saloon, but just outside liquor is extensively sold, and the wholesalers, much to the regret of the company, do a large trade in the town itself.



Another table and chart show that July and August have the greatest accident frequency. It is doubtful whether much can be determined from this information without a segregation of the accidents of mine workers and day hands and without some information as to the number of days worked in each month in the years under consideration. The Ellsworth Collieries Co. works more steadily than many others, and being the adjunct of a steel plant and having coke ovens, its operation is doubtless more evenly balanced throughout the year than is the operation of most mines, but still it is not safe to assume an equality of operation



ELLSWORTH CASUALTIES CHARTED BY MONTHS IN YEAR

month by month; in fact the summer months were probably the least active and yet had the greater number of accidents.

The distribution of accidents by occupations is interesting but without a table showing the number of

ELLSWORTH FATALITIES AND TONS PER FATALITY FROM 1907 TO 1917

RELATION BETWEEN EXPERIENCE AND RISK AT ELLSWORTH, 1916 TO 1917

men engaged at the various kinds of work thus listed it is impossible to draw any conclusions except perhaps that the snapper and in less degree the motorman, like the train hand on the railroad, is exposed to the worst of all conditions. The danger from mine cars continually grows with the increased speed and increased length of trips. If anything goes wrong with the snapper in the rear of the trip, the motorman knows nothing of it as the noise of the trip and the distance between these two coworkers make it impossible for them to keep in touch.

The record of tons per fatal accident shows remarkable improvement until 1917 when the record falls to the level of 1913. In most mines 1917 was a year of increased fatality per ton of coal, the increase arising apparently from the hurry with which the work was performed.

One interesting chart shows the distribution of accidents with years of experience of the employee, how

RELATION BETWEEN AGE AND ACCIDENTS AT ELLSWORTH, 1916 AND 1917

many employees there are with a given number of years of experience and the relation between accidents and men employed for any given number of years of experience. It seems to show that the greenhorn with less than a year's experience is a poor risk. Experience and observation seem to improve him and when he has been between a year and two years at the work he is a fairly safe employee.

But the third year ushers in a period of risk taking. He appears to have become sure that the dangers will "never get him" and as a result he is "frequent deceased" after two years' experience. Gradually he appears to learn better. In the "5-plus" year he has become a "safety fan." He no longer believes in tempting Providence. Though there are wriggles in the percentage curve thereafter, on the whole it is a descending curve to the last.

All this is very consoling. It shows it is easy to teach safety to the greenhorn and it proves that the older men are willing to stay taught. But in between there is a peak exhibiting a disposition in the new man to "sow his wild oats in the safety field." This disposition can surely be eliminated by suitable safety propaganda.

The thorough investigation of the Ellsworth Collieries Co. seems to show that the old miner with his set ways is not the big offender. It is the young man with the wine of life in his veins and strength in his limbs who is willing to take and does take a chance, not because he is convinced that a certain course is safe enough but because he just delights to gamble with death as he likes to gamble with the contents of his pay envelope.

Let the young, inexperienced miner see that achieving safety is just as well worth while as playing with danger and he will become a safer employee. Every young man has ideals and works toward them. If they are ideals of foolhardy courage he will follow his ideals to his death. If they are ideals of safety and thrift, he will follow them through a long industrious life of good citizenship to an old age of comfort and honor.

An Iniquitous Custom

A criminal action was heard in the coal mining town of Fernie, B. C., recently which created something of a furor there and held the attention of coal mine operators and miners throughout the province. The circumstances, in a few words, were that a miner employed by the Crow's Nest Pass Coal Co. was accused of loading a number of cars and placing his tally check thereon while supposed to be on company work and paid by the company. Thus he got double pay—pay at the stated rate for company work and pay, under the contract system, for the coal loaded, which in the ordinary way was credited to him.

Witnesses for the defence testified in effect that it frequently happened, so frequently as to be almost a custom, that subofficials would allow contract miners, while working on company time, credit for coal loaded by them on contract basis in addition to the regular schedule for the company shift. It was alleged that the motive for this was to "speed up" operations by hastening the expeditious completion of necessary work and avoiding undue interference with production.

On the other hand company officials and subofficials entered an emphatic denial of the existence of such a system. The secretary of the local union declared that the practice was common but repudiated it, stating that it was not followed with the approval of union officials.

The Court in fining the accused $100 or six months in jail said: "If this custom did exist, it is a criminal one. I do not care if a few overmen or firebosses connived with the workmen; it was a criminal one undoubtedly. I do not share Mr. Phillips' (witness for the defence) Bolsheviki idea that it is all right to steal from your employer but not from your fellow worker. I do not think any right thinking man will agree. But, as I say, if it was a custom, it was a criminal one and one a man should be punished for."

Progress in Accident Prevention

What the National Safety Council Has Accomplished in Safeguarding the Workman—Nothing Can Be Achieved Without the Earnest Co-operation of the Workers Themselves—Education in Safety Should Begin in the Home—How the National Safety Council Has Grown

THE development of the science of accident prevention in America within the last five years has been summarized in a single phrase, "Nothing is so valuable economically as the man." Outlined briefly, the following have been found to be the essential features of accident prevention work:

1. To ascertain the actual conditions of risk under which employees perform each task and to determine the practical methods of eliminating or reducing this risk.

2. The provision of proper working conditions and of efficient safeguards for dangerous machinery and appliances.

3. Careful selection, instruction and supervision of workmen, and their assignment to work for which they are best suited.

4. The promulgation and rigid enforcement of necessary rules for safeguarding.

5. The inculcation of habits of caution in the minds of all concerned.

Actual conditions of risk, five years ago, were usually summarized as follows: Industrial accidents, fatal, one every four minutes; non-fatal, one every four seconds. Only male workmen were taken into account and no reference was made to the many women and minors engaged—probably because no statistics were available. Elimination of risk has not been achieved or even approached, but a start has been made, approximating reductions of 15 per cent. in fatal and 40 per cent. in non-fatal industrial mishaps. Members of the National Safety Council who have carefully compiled statistics covering the five-year period report even more satisfactory totals, a few declaring reductions for both fatal and non-fatal classifications of 65 to 85 per cent.

The attempted achievement of proper working conditions and the standardizing of safeguards on dangerous machinery and appliances have revolutionized modern industrial methods, particularly when applied to plants engaged in "quantity production." Starting with the fundamental principle of installing only safe machinery and equipment, plant managers demand of machine builders that every guard of known merit shall be incorporated in the design of the machine. In the present day workshop the executive strives to embody in every operation, beginning in the drafting and planning departments, provisions for safeguarding his workmen. The purchaser of a crane, for example, can now secure a completely appointed device—fully as efficient as any previous model, plus a full complement of guards.

Manufacturers of woodworking devices have gone further, probably, than any other group of machinery designers, and shapers, jointers, saws and planers are usually fully protected. The same may be said, varying only in degree, for the manufacturers of lathes, cutting, stamping and boring machines commonly found in workshops of every character. In the operation of such machinery, however, plant executives, even through the most careful supervision, have not succeeded in achieving entire elimination of work accidents.

In older installations the safety engineer and department foremen are relied on to design and fabricate most of the guards. Certain large industries have systematized the designing, building and installation of guarding devices by turning the work over to a special department, and men engaged in this work are not called upon to take part in production. Remarkable results have been achieved, but as yet, although records in accident prevention show reductions of 85 per cent., no safeguard, however elaborate in design and efficient in operation, is claimed to be "fool proof." Accidents still occur.

Careful selection, instruction and supervision of workmen and the assignment to them of work for which they are best suited may be said to start in the home rather than in the factory, workshop or mill. Education in safety begins with the parents, continues in the schoolroom, and finally reaches the employment manager or foreman.

A score of American cities have attempted civic safety work, notably Rochester, N. Y., where a campaign of education embracing every phase of home, street, public and industrial accident prevention is being carried on. Thousands of educational bulletins, changed weekly, have been printed and displayed, and the lessons have proved of intense interest. Scenes familiar to every citizen of Rochester have been utilized to drive the lesson home, and it is a safe prediction that the campaign will prove of lasting benefit.

Special series of safety bulletins are available for use in public schools, and in many communities these are proving valuable aids to teachers in safeguarding pupils to and from their homes. Primary lessons in crossing streets, avoidance of traffic accidents, safety at play and in the home are taught in the lower grades, while in the advanced grades more comprehensive lessons are offered.

Carrying the idea to a logical conclusion a national committee is now at work formulating a scientific course for students of technical schools and universities. The need for such a course is emphasized by the establishment in western Pennsylvania of a private course in safety engineering, under the auspices of a local branch of the National Safety Council, the industries being unable to secure a sufficient number of technically educated men to fill the positions awaiting such engineers.

Supervision, whether in production or in accident prevention, is one of the most important of industrial problems. In safety work it has often been said that "without the whole-hearted coöperation of the foreman all efforts in accident prevention must fail."

Adopting the experience of safety engineers it has been found advisable, if not imperative, to enlist the services of the general manager not only in enforcement

but in every stage of preliminary planning; this secured, the executive staff accepts as the policy of the establishment the slogan "Stop the Accidents," or as more popularly phrased, "Safety First."

The management, the planning staff and the foremen working in unison, the employment manager is next in line for conversion to the movement. This is well emphasized by the present plan in certain large industrial plants of charting every position in the works and the acceptances by the employment managers of partially incapacitated men or women for lighter service. The plan, too, has worked well in returning injured men to work. Men incapacitated because of injury to a lower extremity are found places where service may be performed while seated, as has been repeatedly proved to the satisfaction of both employer and employee.

The promulgation and rigid enforcement of necessary rules for safeguarding has worked out in actual practice to an advanced stage of mutual coöperation. Success in drafting shop rules for accident prevention has been attained when shop safety committeemen serve on boards organized for the formulation of accident prevention standards. In fact, next to the general manager and his superintendents, the members of the shop safety committee are the most valuable safety boosters in the plant.

Safety rules are often augmented by bonuses, prizes and rewards of various kinds, and these serve to inculcate the habit of caution in the minds of all concerned. That "the best safety device known is a careful man" is an aphorism of proved merit. Discipline has its value, but watchful care must be exercised to prevent foremen from confusing discipline with peevishness or "nagging" of workmen. Proneness to follow precedent in operation, while excellent in maintaining discipline of a sort, is destructive to best results in safety work—change of process, equipment and operation calls for complete revision of method, and gradually habits of personal caution and thinking observance of safety standards are revising experience tables of lost-time mishaps in the industries of the country.

History of the National Safety Council

ON SEPT. 20, 1912, the Association of Iron and Steel Electrical Engineers met in the city of Milwaukee and following the report of the Committee on Accident Prevention, resolved to launch a national coöperative movement for the dissemination of policies and methods worked out in the steel industry and found effective in reducing the number and severity of industrial accidents.

Forty delegates attended the First Safety Congress, meeting jointly with the Iron and Steel Electrical Engineers. An outline of procedure was adopted, together with a constitution and by-laws, and the work of scientific accident prevention became an integral part of American industrial life. Federal and state officials were in attendance and took active interest in the work. After several days of discussion and careful planning, a central body was established known as the National Council for Industrial Safety. For convenience of classification, departments were established to popularize and further the movement, and the close of the Congress found the organization ready to take up safety work in the mining industry, on the railroads, in manufacturing and among iron and steel companies.

The new organization grew and prospered. A weekly safety bulletin service was established and has continued without a break for more than four years, growing to a distribution of 75,000 copies per week. Statistical researches were made and tabulated, and practical value given to shop activities. The innovation of using available data in the simple and effective form of one-page illustrated bulletins, rather than in the compilation of massive treatises, proved the value of the Council's services in presenting the lessons in readable form, fresh from the press. The Council doubled its membership and greatly increased its usefulness in the second year.

The Third Safety Congress was held at the Hotel LaSalle, Chicago. This series of meetings was epoch making, both in attendance and interest; it was at this Congress that the industrial medical practitioner first made his voice heard. Plant managers learned that the installation of adequate mechanical safeguards did not comprise their entire duty. Sanitation, ventilation, control and eradication of industrial disease, elimination of infections—all these and other questions were placed on the program and thoroughly discussed. Tuberculosis, blood poison, hernia, eye strain and excessive fatigue were handled in a way to awaken the interest and cooperation of the large audiences.

A year of intense activity followed. With a broadened scope of activities the association changed its name to the "National Safety Council." The program of the Third Safety Congress furnished the text for the activities of the officers and members, and the work was carried on with renewed enthusiasm. The membership doubled, and with every mail came scores of experience statements from plant officials. These were compiled, digested and reissued for the information of the whole membership. It is significant of the interest taken in the work that the master minds of industry have cheerfully and unostentatiously given so liberally of their time and experience for the causes of safety and humanity.

The Fourth Safety Congress was held at the Bellevue-Stratford Hotel, Philadelphia. To meet the demands of the Congress it was necessary to again divide the Council into new sections, each group meeting being larger in attendance and more ambitious in program than the first congress at Milwaukee. The Governor of Pennsylvania, the mayor of Philadelphia, the press and the public united to further the propaganda of the congress.

After the preliminary "round table" gatherings, devoted to general discussion, ten sectional meetings considered the particular safety problems of their industries. The Cement Section took a leading part in the congress, as did the Mining, Steam Railroad, Laundry, Paper and Pulp Manufacturers, Public Utilities, Textile, Industrial Hygiene, Safeguarding of Machinery, Foundry and Woodworking Sections.

It was at this gathering that the greatest truth in the safety crusade was forcibly driven home to plant managers, safety engineers and the public: That all the safeguards, all the rule books, all the discipline, and all other efforts must fail without the earnest and willing coöperation of the workmen themselves. Millions of dollars had been expended by members of the National Safety Council in perfecting mechanical safeguards in their plants; other millions went for sanitation, for ventilation, for preventive measures, yet the men vitally affected too often showed only a perfunctory interest in their own welfare.

A score of addresses and lectures were delivered at the Philadelphia Safety Congress, pointing the way to success in administering safety work—the way to the hearts of the millions of men and women toiling in the industries. The visiting nurse, the industrial physician, the dentist and the teacher came forward and joined the employer, social worker, priest and parson in teaching applied and practical Christianity. Industrial justice was the keynote of the congress.

Another important lesson was gleaned from the wealth of digested experience and statistical data furnished through the medium of the parent body—the National Safety Council. Where one accident was prevented through safeguarding, three were prevented by the exercise of personal care and caution by the workmen themselves. Where one case of industrial disease was prevented in the shop or factory, two were susceptible of prevention and cure in the home life of employees.

From the time of the Fourth Safety Congress the importance of education, rather than compulsion, in safety matters, was given prominent place in the activities of the movement. The elasticity of safety work was never better exemplified than during the succeeding year. Employers who had held aloof, waiting for the movement to prove itself, came forward in whole-hearted recognition of the justness of the plea for a larger humanity. From an organization struggling to meet the patent demands made upon it in the simple necessities of every-day life, organized accident prevention, almost in a day, was placed beyond the need of financial worries.

From the Fourth to the Fifth Safety Congress the membership again doubled in number; the work of the sections was improved, an increased staff at headquarters facilitated the activities of the officers and the newer phases of safety work were pushed with unrelenting vigor.

The Fifth Safety Congress was held at the Hotel Statler, Detroit, and the Sixth Congress at the Hotel Astor, New York City. Perhaps the most important contribution to the cause of safety during this period was the organization of an information bureau and library containing every scrap of printed material available, touching on the work of accident prevention. This information bureau, at present in charge of three trained librarians, classifies and files all available data, sending it to hundreds of inquirers every month. Among the duties of a staff of safety engineers is the classification and preparation of the material for suitable bulletins and publications for employers and safety engineers to properly start them in new activities. For the year ending Apr. 1, 1918, five million bulletins were distributed to fifteen thousand representatives scattered in all parts of the country.

During the year 1917 a monthly pamphlet, "Safe Practices," was born; this is an encyclopedic work destined to take its place in literature with the foremost handbooks of accident prevention. A modest number on "Ladders" was followed by others on "Stairs and Stairways"; "Boiler Rooms"; "Crane Construction and Safe Practices"; "Knots, Slings, Bonds and Hitches"; "Belt Shifters," etc. In time, it is intended to present every phase of industrial education, and by rule, illustration and practice complete a digest of safe practices for the prevention of accidents in every branch of industry.

MEN WHO HAVE GUIDED THE DESTINIES OF THE NATIONAL SAFETY COUNCIL DURING THE PAST YEAR

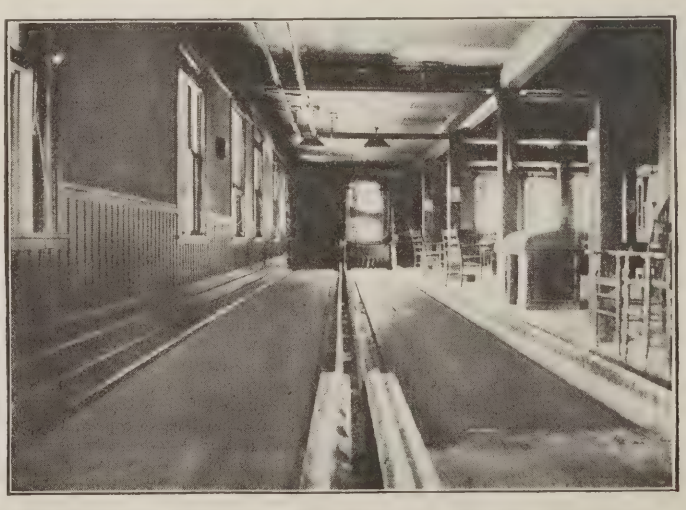
Y. M. C. A. Building vs. "Y. Hut"

BY CHARLES F. WILLIS
Consulting Supervisor, Department of Industrial Relations, Phelps Dodge Corporation, Bisbee, Ariz.

Though the illustrations and story are based on the experience of a copper corporation, which is practically identical with the Stag Canon Fuel Co., a large coal-operating concern, the ideas given are quite applicable to coal mining. The article was prepared specially for us by the author.

A PROBLEM that is now being faced in many states of the union, and one which probably will soon be confronted all over the country, is how to replace saloons in mining and industrial communities by other places of entertainment. There have been many experiments along this line. Some believe that the motion-picture houses have already to a large extent replaced the saloon. Without a doubt, many who formerly were accustomed to loaf around saloons now attend motion picture houses, but these institutions are a partial substitute rather than a replacement.

It is not a logical replacement in that it provides none of those things that made the saloon attractive as a place in which to spend one's leisure time. It is not natural for a man working underground in the semi-darkness and in a more or less close atmosphere to select similar conditions for his leisure hours. Recreation rightly understood involves a change of conditions from those obtaining during working hours.



Since the abolition of the saloon in "dry" states there have been many soft-drink parlors established—this being another method of replacing the saloon. While this is a more logical method of meeting the difficulty, these places of entertainment have not proved successful. As business ventures they have paid, but they have not supplied the element of sociability on which the saloon keeper of the past relied as a means of attracting customers. In a soft-drink parlor a man usually goes in, gets his drink and comes out, staying no longer than is absolutely necessary for that purpose.

In certain mining communities there has been an attempt to replace the saloon by Y. M. C. A.'s, at which every conceivable equipment has been provided that in any way promised to furnish a substitute for the allurements of the saloon. There is grave doubt, however, that they reach the men who were accustomed to frequent the bar room.

Notable among the mining camp Y. M. C. A.'s is that provided by the Phelps Dodge Corporation at Bisbee, Ariz., where a fine building has been erected with practically everything in the line of "Y" equipment—pool tables, bowling alleys, swimming pool, gymnasium, motion pictures, educational classes, reading room with library and religious work. One might go through the entire list of Y. M. C. A. activities and find none of them missing in this organization. It has been remarkably successful, and now has some 1800 members, about 1000 of whom are miners, and the community has been much interested in its development. Its success has been apparent; it fills a place in this community that no other organization could fill, but there is again serious doubt that it actually replaces the saloon.

Another institution to replace the saloon is the employees' club, which is somewhat different in nature from the typical Y. M. C. A. The Morenci Club is an activity of this kind. It is also found at a village of one of the Phelps Dodge subsidiaries. A splendid building has been provided and the club serves as a recreational center for the people of the town. This organization is run partly as a business proposition; pool tables and bowling alleys are provided at about one-third the usual cost of these things; the best motion pictures are secured, even though it is done at a loss, for the company desires to educate the taste of the people for the best films. The club was designed to be a loafing place for all, irrespective of nationality or religion, to serve as a place where properly supervised entertainment could be obtained at a reasonable price. This institution also has a distinct place in the community, a definite need which it fills; but here again the question arises, "Is it actually replacing the saloon?"

MORENCI CLUB, MORENCI, ARIZ., AND A VIEW OF THE CLUB BOWLING ALLEYS

Y. M. C. A. AT BISBEE, ARIZ., BUILT BY PHELPS DODGE CORPORATION AT A COST OF $116,000; CLOSE UP OF ENTRANCE IS SHOWN ON RIGHT

It might be well here to analyze the saloon and the features of it that need replacement, to see whether or not the various substitutes do fulfill these needs. Saloons are usually placed conveniently to the homes of their prospective patrons; as the town grows, more are found, in locations convenient and easy of access. Comparatively few men go to a saloon primarily to drink. They go there because it is convenient, because it is a place where they will find congenial company, and they gather there in groups sufficiently small that all present may enter into close companionship.

They like the saloon because the equipment and the surroundings do not make them feel out of place, no matter how they may be dressed. They like its free and easy air. There are no restrictions; they can make all the noise they please or be quiet if they so desire. They buy drinks because they feel that it is only fair to the saloon keeper that they pay him something for using his building as a loafing place. This is not true in all cases, of course, but it is undoubtedly true of many persons. Many a man's first attraction to the saloon is the opportunity it affords to associate with the people who frequent it. It is only later that he gets the drinking habit and goes there for the express purpose of drinking.

Does the soft-drink parlor, the fine Y. M. C. A., or the commodious employees' club fulfill these conditions for the man who ordinarily used the saloon? As a rule these organizations are so large that intensive sociability is difficult. Yet they are not large enough to accommodate readily the many men who formerly used the saloon as a poor man's club. Y. M. C. A.'s and employees' club buildings are generally costly, it being the desire of the mining companies to erect something for their employees that is worth while. Fine lobbies, huge leather chairs and many luxuries are found, which are not a part of the saloon atmosphere or of any atmosphere to which the workman is accustomed. To make use of these places he instinctively feels that he has to don a white collar.

In most mining camps the working force is composed of men of many nationalities, and one saloon or another gradually becomes the loafing place for men of some one of the many nationalities represented. We find that there is little mixing between the people from different countries. In the case of the Y. M. C. A. or the employees' club, however, an attempt is made to mix these races. Moreover there may be but one, or there are, at best, but two Y. M. C. A.'s or clubs in a large community. If that community is not spread over a large area it is easy for every man to take advantage of the entertainment provided, but in many mining villages the distances are too great for that to be done. Men seek their social pleasures at the nearest point to be found, particularly after performing a hard day's work.

Now comes the question as to what features of the saloon can be provided, where they can be provided, and in what manner administered, so that they will reach the people whom the saloon is designed to accommodate. I believe that it is possible to supply everything that the saloon provided with the exception of alcoholic drinks, to provide them under some supervision and to give them all the features, with the exception of the bar, that has made the saloon attractive.

What is it, then, that draws men to the saloon? Bright lights, warmth and comfort, a building not so fine but what the workmen could feel at home, regardless of his dress, a place small enough for intimate social relations and a place convenient to his home. The saloon substitute will have to provide these, and an additional something to provide for the time which in the case of a saloon is spent at the bar.

May we not learn something from the Army Y. M. C. A.? This organization did not go into a cantonment of 30,000 men, put up one fine building and expect the men to use the building in common, but rather it put up eight or ten or even more huts. Is it not possible to follow out this same idea in mining communities? This does not mean necessarily putting up shacks, but rather buildings that are one or more steps up in quality and surroundings from the saloon. It is a case of educating the people to better things, but this cannot be done in one jump.

Why not provide in each residential section of a mining camp a neat but inexpensive building, measuring possibly 20 x 40 ft., containing two or three pool tables, a couple of card tables, a branch library, with magazines and newspapers, an electric piano for music, and a counter where smokes, candy and soft drinks could be purchased? One of these could be erected for each one

thousand of population, and it could be located near the homes of its prospective patrons.

The mining companies operating in these communities should furnish these buildings, as private capital could not afford to indulge in experiments of this sort. The substitute could not expect to make profits as generous as the saloons. The saloon keeper often provided several questionable attractions to draw people to his place of business, but his temperance rival could hardly vie with him in this business.

Not only is it necessary that the company should stand behind the ventures financially, but it is advisable that it should finance and control the institutions, for then they will not be run merely as business propositions. There will be much in the way of price and other regulation. The plan fits itself readily to every size of community. The buildings need not be uniform in size, and in fact where there is much racial diversity, more and smaller buildings would seem to be advisable.

There are several ways in which these "huts" could be administered. They could be organized as Y. M. C. A. substations, and under such organization could include many advantages of the "Y." They might be put under direct supervision of the company, and a man employed to run them, who would be given a guaranteed salary or a percentage of the profits. Either of these plans would probably be preferable to leasing the buildings to concessionaires. The scheme appears to afford a cheaper and more satisfactory plan of replacing the saloon than many of these hitherto favored.

This Company Gives Its Girls a Good Time

FOR a number of years E. H. Morand, superintendent of the schools of Sopris, one of the Colorado Fuel and Iron Co.'s operations, has yearly taken some of the boys of the company's villages on a camping trip, sometimes quartering them in a house but more usually erecting tents for their accommodation.

When Miss Miriam C. Dawley came to Primero in 1916 to be the first community secretary engaged in connection with the Young Men's Christian Association's activities of the Colorado Fuel and Iron Co., she extended this good work by taking about 45 girls from four of the mining towns of that concern for a similar outing in the woods. On this first trip they slept in a schoolhouse and used an abandoned boarding house for kitchen and dining room. Last year the girls obtained the use of the country club at Stonewall. Eleven of the Colorado Fuel and Iron Co. camps were represented and 79 girls in all attended.

These camping trips have been so successful that the company officials decided to build and equip a lodge that could be used as a permanent camp for both boys and girls. The site selected for this lodge is in a most picturesque place near the natural wall of stone at Stonewall, Colo. The building is located in a beautiful pine grove and has been christened the "Camp of the Whispering Pines." The main hall is 25 x 56 ft. and has an immense stone fire-

WITH EXERCISE LIKE THIS THE GIRLS OF THE FUEL AND IRON CO. DEVELOP THEIR LUNGS AND SQUARE THEIR SHOULDERS

Above—Return to camp after night spent in the mountains. These girls went up high enough to find a large snowbank. Below—Setting-up exercises at 7:15 a.m. The lodge is in the background. Here, first the girls and then the boys are entertained.

place at one end. This room is used as general assembly room, for games, dances, classes and dining room. The dining tables are portable and are moved out of the way when not in use. The company has furnished all the equipment, including 60 folding cots; the best grade of enamelware, silver knives, silver forks and silver tea, soup and tablespoons, sufficient glassware, a complete set of kitchen utensils, a pressure cooker or digester, a hotel range and hot and cold water. Four shower baths and dressing rooms are being built and a telephone installed. Before the next camping season the kitchen will be remodeled, a new pantry storeroom added and barracks will be built. This will make the camp quite complete and give every facility for comfort and convenience.

This year the girls from 18 of the company's villages, all those that are in this part of the state, were represented, over 200 girls being present. The girls over twelve came in two separate groups and stayed ten days. Another group of girls under twelve years of age stayed for one week. The daily program was as follows: Rising bell, 6:45; setting-up exercises, 7:15; devotional service and flag raising, 7:30; breakfast, 7:45; cleaning up of building and grounds; folk dancing, 9:30; painting and stenciling, 10:00; first aid, 10:30; Red Cross, 11:00; dinner, 12:00; rest hour, 1:00; recreation, 2 to 5:30; supper, 5:30; stunts, 7:30; retiring bell, 9:00; lights out, 9:30.

The company furnished all the girls with transportation from their home to camp and return. As the ground is located 13 miles from the railroad, the girls were taken to and from the station by automobiles furnished by the company. A trained nurse, paid by the company, looked after the physical welfare of the girls and taught first aid. The different camps took turns in putting on the stunts in the evenings and gave many clever performances, which were appreciated by the audience.

On June 23 the lodge was formally opened. Several officials of the company were present and the building was presented to the girls and boys of the Colorado Fuel and Iron villages by S. G. Pierson, vice president of the company. An interesting program was given, the meeting being attended by large numbers of the friends and families of the girls.

The boys' turn followed soon after the girls' closed and was attended by about 100 boys. These camps have been so successful and have been so thoroughly enjoyed and so beneficial to the girls and boys that a more extensive program is already being planned for next year.

We are apt to deplore the fact that some of the men at the mines are prone not to use the best judgment as to the use of their leisure moments. Their ideals and those of their families, we are disposed to declare, are not of the best. Perhaps there has been no attempt, as here at the "Whispering Pines," to uphold higher ideals of amusement and community service, and that may account for the fact that pleasure is sought where only pain and discouragement are to be found.

Safety in the Use of Explosives*

By ARTHUR LA MOTTE†

The development of measures and appliances for avoiding accidents incurred in the use of explosives and for minimizing their results has been the subject of careful study and experimentation. Though there exists among mining men a general familiarity with specified precautions, a closer analysis of the recommendations made by manufacturers is often desirable. The list of "don'ts" seems formidable, but it should prove interesting to mine executives, foremen and workmen.

IT HAS been maintained that it takes three generations to make a gentleman; the same may be said of a man who can be depended upon to engage in hazardous work with a maximum of safety. One must begin with his grandfather. The primary characteristics of the safe man are unselfishness and consideration for others. Personal bravery and nerve, or cowardice, has nothing to do with it. Thorough knowledge of the subject has a great deal to do with it. The most unsafe man on dangerous work, or, rather, in handling dangerous goods, is the man who is afraid to be afraid. He may know that the thing he is doing is dangerous—he may know that it is dangerous to remain where he is under certain conditions—but he is often afraid to take cover himself or to warn others, or to take ordinary intelligent precautions, for fear of being thought afraid.

Timid Attitude of Foremen Detrimental To Best Safety Practice

I remember being in a mine some years ago where five men were killed by the tipping of a skip while it was being hoisted, because several of the men rode on the bail, causing it to tilt in front and engage a crosstie. Positive orders were thereupon issued that no one should be allowed to ride on the bail; and yet, only three days later, when I was coming out of the mine, in company with the foreman and several others, the skip was stopped and several men got on and climbed out on the bail. When the foreman remonstrated with them, saying that this was against orders, one of the men sneeringly remarked: "What's the matter with you? Are you afraid?" This instantly silenced the foreman, who made no further objection, and we went out under exactly the same conditions as those which were known to have caused a fatal accident.

The prevention of this type of accident, it seems to me, can be accomplished only by discipline, laying down hard and fast rules and enforcing them ruthlessly. Education, which is effective in preventing a large class of accidents, seems to be helpless here. If possible, rules should be made so inelastic as to prevent even the officers of the company from violating them. In the army, for general safety, even the commanding general may not do certain things, and I feel it would have a beneficial effect on industrial workers if they knew that their chiefs were not allowed to do various dangerous things which are forbidden the workers.

To return to the subject, it is necessary, to an extent, to begin with the grandfather of the dynamite; that is, the raw materials. These are purchased on specifications, submitted to a rigorous analysis, and are carefully inspected, sorted and strained. The inert or non-explosive ingredients which enter into the manufacture of explosives are just as carefully treated as are the more essential ingredients; and this inspection is brought right up to the last process in the course of manufacture. For instance, the wood meal and nitrates are given the final sieving in the mixing house just before they are put into the tub and incorporated with the nitroglycerin. This latter ingredient is put through a series of processes which would delight the heart of any safety man. From first to last it is "handled with gloves," generally rubber gloves. After separation from the acid it comes in contact only with wood or rubber. It is washed and stored in wooden tubs under water. It is drawn off through rubber pipes, the flow through which is stopped by elevating the end of the pipe. It is weighed in rubber buckets and is transported either through rubber-lined gutters by gravity or by a rubber-tired traveling tank with a rubber hose for a spout. Buildings are floored with rubber and the workmen wear rubber-soled shoes. The scales are covered with rubber, both the platform for the box and the platform for the weights. The weights also are covered with rubber. The operation is carried out in a frame building having an earth embankment entirely surrounding it as high as the eaves of the building itself, and this building is kept as far away from every other explosive building as the experience of the plant engineers shows to be necessary. After the dynamite is made, it is transported, in the process of being punched and packed, in wooden boxes having no exposed metal parts, and is punched with soft rubber-tipped wooden sticks. Special shoes are worn throughout the danger area, and the floors of the buildings have coverings of soft rubber-like material which can be taken up from time to time and burned.

Precautions Developed from Classification Of Accidents

For a number of years a list of accidents in the use and handling of explosives was kept, compiled from the British and Canadian government reports and supplemented by an elaborate system of American newspaper clippings. The object was to classify the accidents which happen in the use of explosives in such a way that a brief list of precautions could be made up which would cover practically every condition likely to arise in the use of explosives in mines, quarries or on construction work. The list is added to from time to time, whenever a new cause of accident is reported. It is not always possible to be specific, but that the list covers the ground fairly well is shown by the fact that in the last few years no accident has been brought to the attention of the du Pont de Nemours management which is not

*Paper to be read at the September meeting of the National Safety Council.

†Manager, technical division, E. I. du Pont de Nemours & Co., Wilmington, Delaware.

covered by the rules and which would not have been prevented had all of the precautions been observed. This list of precautions is printed in the company's catalogs, and I will take each rule in turn and try to explain the reason and necessity of the precaution.

All rules begin with the injunction "Don't." I remember reading this list at a convention of coal miners a few years ago, and one of the miners told me at the end that if he obeyed all the rules he would not be able to use explosives at all, but when I asked him to describe in detail each of the different operations through which he went in his blasting, I showed him that at no time did he do anything in violation of these rules, which was probably the reason why he had never had an accident with explosives.

"Don't forget the nature of explosives, but remember that with proper care they can be handled with comparative safety." The function of explosives is to explode, and a perfectly safe explosive would be useless. The company has always tried to avoid describing any explosive as safe, but explosives can be used in such a way that accidents are avoided, and for the man who handles explosives a good thought to carry is: "Don't take a chance, and don't try conclusions with dynamite." It is dangerous, of course; but so is a mine mule, and both the mule and the dynamite will perform their allotted work and render good service if treated with the proper amount of respect.

Danger of Smoking and Use of Open Lights

"Don't smoke while you are handling explosives, and don't handle explosives near an open light." Not all explosives ignite from a spark with the same facility. Blasting powder and nitro-starch powders are most easily ignited. The paper shells covering dynamite give it a certain amount of protection, but there is considerable difference, even among the various kinds of dynamite, in the ease with which they are ignited. Straight dynamite ignites more easily than ammonia dynamites and gelatins. The permissibles of the ammonia-base type are least easily ignited. A pipeful of ignited tobacco spilled in an open box of dynamite would probably ignite it; it would certainly ignite blasting powder. Open lamps on the hats of men who carry the dynamite around in the mine are distinctly dangerous, as sparks are continually falling from wick lamps, and, although acetylene hat lamps are safer, I have seen a lighted lamp drop into a box of dynamite. The best practice is for powder men to be equipped with permissible electric hat lamps, which are the safest lights known. It is thought that the Park Avenue explosion in the New York subway construction was brought about by a man bringing an open light into the powder house, where a number of detonators had been inserted into the dynamite. I remember seeing a drill runner drop an open bug-light into a lot of paper shells which had been removed from several boxes of gelatin dynamite and which entirely covered a box of primers. This was in one of the New York subway tunnels and probably closely paralleled, except for the result, the Park Avenue explosion.

"Don't carry loose matches in your pockets while loading explosives—use safety matches." A number of accidents have occurred from the dropping of matches from hat bands into bore holes which were being loaded with dynamite. Quarrymen frequently appoint a number of laborers to fire the block-hole and mud-cap shots, for the lighting of which they fill their pockets with matches and stick half a dozen into their hat bands, so that in case one match goes out at a critical time they can quickly lay hand on another. These men are called upon, in the loading of a large blast, such as well drill holes, to assist the blasting foreman, and it seldom occurs to him to take matches away from the men, especially out of their hat bands. In leaning over the holes, matches stuck into the hat band are likely to fall into the bore hole and fire the dynamite. Though dynamite will usually burn peacefully in the open, it cannot be depended upon to do so in a bore hole, and will certainly explode if the detonator has been inserted.

I almost hesitate to read the next rule on the list, as it would seem that no one out of an insane asylum would require it, yet the failure to observe so obvious a precaution has been the cause of many serious explosions. "Don't shoot into explosives with a rifle or pistol, either in or out of a magazine." To an intelligent man it would appear to be a plain case of suicide, and yet not many years ago a customer tried to convince one of the company's salesmen that the dynamite would not explode if fired into with a small-caliber rifle bullet. The customer tried the experiment in his cellar, shooting into several cases of dynamite which he had stored there. However, he failed to prove his point, as the dynamite did explode, killing the experimenter and his entire household. "Don't allow shooting or hunting near magazines." Though magazines should be bullet proof, it is seldom that they are, and, even if they were, the doors are likely to be open when explosives are being carried in or out. The risk of a disaster is too great for any sensible person to take any chances.

Careless Deposition or Storage of Explosives

"Don't leave explosives in a field or in any place where cattle can get at them." Black powder probably would do them no harm, but nitroglycerin is a powerful poison. Although cattle like the taste of the soda and nitrates in dynamite, the other ingredients would probably poison them. "Don't handle or store explosives in or near a residence." In some parts of the country it is the custom for miners to buy their own explosives and take home what they do not use in the day's work. This introduces a great hazard into the home, both on account of the possibility of children getting hold of the explosives and because of the danger in case the building should take fire. The new Federal regulations governing the handling of explosives will probably result in fewer accidents from this cause.

"Don't leave explosives in a wet or damp place. They should be kept in a suitable dry place, under lock and key, and where children or irresponsible persons cannot get at them." There is an increased effort in the matter of conservation to use nitrate of ammonia explosives, which require less nitroglycerin. Nitrate of ammonia explosives are more hygroscopic than other types, although any explosive will deteriorate when stored in a humid atmosphere. Probably the chief cause of explosives taking on moisture is storage in magazines built into the side of a hill in so-called dugouts. The actual loss in dollars and cents from this kind of treatment of explosives is considerable, but there are two

reasons from a safety standpoint why explosives should be kept dry. In the first place, wet dynamite and wet blasting caps produce only a partial detonation, which is likely to cause a blown-out shot, and is highly dangerous in coal mines containing inflammable gases or dust. Secondly, the fumes from a partial detonation are more poisonous than those from explosives which are in good condition and explode perfectly. Dampness in blasting caps is a prolific cause for dynamite igniting instead of detonating, and a charge of burning dynamite in a bore hole fills the working place with extremely poisonous fumes. At present more care is taken to keep explosives under lock and key than was the case a few years ago. Blasting caps are particularly attractive to children, and from 30 to 50 accidents are caused every year through their playing with them, resulting in the loss of fingers, hands or eyes, and occasionally in loss of life. When one considers that a modern blasting cap will blow a hole through a $\frac{1}{16}$-in. steel plate, and that the pieces of flying copper will imbed themselves in iron two or three feet away, it is not difficult to realize what a power for mischief these necessary articles may become.

"Don't explode a charge to chamber a bore hole and then immediately reload it, as the bore hole will be hot and the second charge may explode prematurely." This operation, variously known as "springing," "chambering," pot-holing," "squibbling," and so on, is done by exploding a succession of charges in increasing amounts in the bottom of the bore hole, with little or no tamping, in such a way as to expand the bottom of the hole, so that a larger charge may be accommodated. In some rocks the enlargement is produced by shearing and scaling off rock from the sides of the bore hole, and in others by compressing the rock itself. This latter, of course, is possible only in soft rock. Considerable heat is generated, not only by the explosive itself, but in the compression that occurs, and unless ample time is allowed between "springing" shots, accidents are likely to occur from an explosion of the charges which may be placed in the hot pocket, or become ignited from fragments of fuse or wire insulation. Of course, when the pocket is full of water and fills up immediately after each "springing" operation, there is no danger from the hole being too hot, but another hazard presents itself in the loading of "sprung" holes. That is the danger of the dynamite, especially when a straight dynamite is used and the cartridges are slit, getting between the cracks and crevices of the rock in such a way that when the hole is being tamped it may be pinched under considerable pressure and cause an explosion. For this reason, dynamite of the gelatin type is much safer to use where this operation is regularly performed, but where gelatin cannot be used the next best thing is not to slit the cartridges.

"Don't do tamping with iron or steel bars or tools.

Fireco—A New Mining

Town in Heart of Coal Region Planned for Social,

ONE has but to look at the view of Fireco, Raleigh County, West Virginia, the seat of operations of the Leckie Fire Creek Coal Co., which bears the name of the company's president—Col. William Leckie, of Welch, and of the Douglas Coal Co., of which Colonel Leckie is also president—to secure some conception of how admirably Colonel Leckie and his associates have planned for the spiritual, social and physical welfare of the employees of the companies named as well as for the production of coal. To any one who knows Colonel Leckie such thoughtfulness on the part of the genial Scotchman, who combines business sagacity with a tender heart, is not surprising.

As will be observed from the view of Fireco, the town is grouped about the schoolhouse, the doctor's house, the theater and the company store. That is the pulsating center of this mining community. The schoolhouse seen in the picture is a large four-room building, well lighted and equipped with all conveniences. The company has also provided a schoolhouse for colored children, equally well lighted and conveniently equipped. The miners' houses are provided with modern conveniences such as electric lights, running water, shower baths or bathroom, sewerage, etc. An up-to-

NEW MODEL TOWN OF FIRECO, IN WEST VIRGINIA, SEAT OF OPERATIONS

Use only a wooden tamping stick with no metal parts." There is great danger in punching dynamite with an iron tamping rod, especially in holes bored in hard rock, but I venture to say that nearly half the miners who use dynamite use their drill steels for loading the charges, and, considering the frequency of this practice, it is a wonder that more accidents do not occur. It would seem a simple thing to provide miners with wooden tamping sticks and compel their use, but a number of them look upon it as a needless refinement, and always having their drill steels with them, they prefer to use them. When powder men remonstrate with them, they say that if the drill does strike a spark it will not ignite the dynamite; that they use it carefully and ram the dynamite in gently. However, it is only the survivors who say this. The men who are killed do not give their versions of these affairs. One of the curiosities of legislation was a bill introduced in one of the state legislatures requiring the use of several inches of copper on the end of the tamping sticks. When black blasting powder was used to a greater extent than it is now, copper was looked upon as a safe material to use with it, because it would not strike a spark, and that same feeling has descended to dynamite, but it is just as easy to detonate a drop of nitroglycerin or a pinch of dynamite with a copper hammer as it is with a steel one.

"Don't force a cartridge of explosives into a bore hole." This is one of the prolific sources of accidents in the use of explosives and one of the most difficult to control. If a miner or blaster has a cartridge of dynamite sticking half way down in a bore hole, it is a great temptation to drive it further by main strength rather than let it go and waste the bore hole and all the labor that it represents. Fortunately, modern explosives, which are much less likely to explode from rough handling than the straight dynamites of 10 or 20 years ago, have reduced the number of accidents from this cause to a considerable extent. The remedy, of course, is to have the drill bits always made to gage, allowing for a sufficient clearance over the diameter of the dynamite that is being used.

"Don't have a wire carrying electric current near detonators or charged bore holes at any time except for the purpose of firing the blasts." One of the dangers of having electric mining or quarrying machinery around explosive operations is the chance of one of the terminals coming in contact with the electric blasting-cap wires. Considering the care necessary to make connections properly for firing the blast purposely, it would seem that this danger is remote, but a number of accidents have occurred through careless placing of light wires. When the blasts are fired by the lighting or power current, it is doubly necessary to observe this caution, because, even with special safety switches, there is always a chance of the workmen becoming confused and connecting the wrong wire. Though the power and

date water-works system gives the community a splendid supply of water.

Even the three-story building which houses the company's store and the company offices is not wholly devoted to commercial purposes, the entire third floor being thrown into one large room used either as a gymnasium or dance hall.

Adjoining the store is a large auditorium building in which every provision has been made for the recreation of mine workers. The auditorium itself, where moving pictures are exhibited, has a seating capacity of four hundred. Another room is set apart as a pool-room. There are also two restrooms in the building in which soda water and beverages of like nature may be obtained. The floor beneath the auditorium room is fitted up as a barber shop. This floor is also equipped with showers.

The plants of the Leckie Fire Creek Co. and of the Douglas company have been electrically equipped throughout. The coal is cut by electricity and hauled by electric power. The mine fans and the big pumps at the pumping station are electrically driven. A large building seen in the illustration houses the machine shop, the blacksmith shop and the electric repair shop.

OF THE LECKIE FIRE CREEK COAL CO. AND THE DOUGLAS COAL CO.

lighting current is generally advised for quarry and construction work in the open, the regular blasting machine is much safer in underground work, as by its use the danger of connecting the blast to a live wire can be avoided, and though in open work the number of shots that it is desired to fire at any one time may be in excess of what the blasting machine can do, it is rare indeed that such necessity arises in mining or tunneling operations. By keeping an entirely different circuit for the firing of the blast, much greater safety in operation is secured, but under no conditions should electric drills, electric punchers or undercutters be operated or other wires allowed around a room where men are charging bore holes for electric firing.

Men Should Be Protected From Blasts

"Don't explode a charge before every one is well beyond the danger zone and protected from flying debris. Protect your supply of explosives, also, from danger from this source." "Don't cut the fuse short to save time. It is dangerous and wasteful of explosive, as it is impossible to tamp such charges properly." There are not many accidents from flying rock where electric firing is practiced, as compared with cap and fuse, because the blaster will not operate the blasting machine if he knows he is in range of the blast, and, even if his leading wire is being continually shortened by the rock falling upon it, he will take care to lengthen it by splicing on other wire until he can get into a safe place; but in quarry work this does not always hold. The blaster is likely to continue to use his leading wire without taking this precaution and get too close to the danger zone. I have seen blasters fire their shots from the cover of an up-turned dump cart while there was an unused half-box of dynamite, with three or four electric blasting caps in it, out in the open a few feet away from them. It would seem an unnecessary hardship to expect the blaster to take all unused explosives and accessories back to the magazine before the blast is fired, as he may have to use some of them in case it became necessary to reprime a bore hole, but it should be impressed upon him that these left-overs should be put in a safe place before the blast is put off.

"Don't hurry in seeking an explanation for the failure of a charge to explode." This is to warn blasters against returning to the face in the event of a hang-fire, until sufficient time has elapsed to render it safe. High-grade safety fuse is a wonderfully reliable device. It is strong, resists abrasion well and stands immersion in water, often for several hours; and it is uniform in its burning speed. Cheap fuse is not regular in its burning rate, is not waterproof and will not stand abrasion against rock in the bore hole nearly as well as the better grades. However, any kind of safety fuse is likely, occasionally, to hang fire. This happens at times from the blaster failing to ignite the powder core, and the jute or cotton wrappings of the fuse may smolder for several minutes and then ignite the core, or, if the fuse is cut in the hole, the powder core may go out but ignite the jute beyond the break, which may cause a hang-fire. It is difficult in experimenting with fuse to simulate the conditions which cause hang-fires, but hang-fires do occur in actual work and are a prolific source of accident.

Accidents happen more frequently, perhaps, from a miscount in the number of explosions. Where eight or ten fuses are lighted simultaneously, two will frequently go off at exactly the same time, making one report. Consequently, blasters are inclined to venture back to the face, even if the reports heard do not tally with the number of fuses lighted, assuming that two or more have gone off together. In the event of a misfire, half an hour is the least time that should be allowed before investigating. Two or three hours is much better, and waiting until the next day is practically safe. Hang-fires can be eliminated by the use of electric blasting caps and electric squibs, and the increased sales of these devices are gradually cutting down the number of accidents from this cause.

"Don't drill, bore or pick out a charge which has failed to explode." A careful miner can sometimes be depended upon to remove the tamping and insert another primer. It is, however, at times safer to drill another hole near the missed one, but this is not practicable in many instances, especially in hard rock and in "sprung" holes. As a precautionary measure against striking the charge in the case of a misfire, it is suggested that a piece of newspaper or a handful of some other easily recognized foreign substance be placed on top of the last cartridge before the tamping or stemming is done. This acts as an indicator, so that the tamping may be removed with comparative safety without any chance of digging into the explosive.

"Don't use two kinds of explosives in the same bore hole except where one is used as a primer to detonate the other." It is a common practice in some sections to place a dynamite cartridge in the bottom of a bore hole and the main charge of black powder on top of that, firing the black powder with fuse or squib. The dynamite explodes from the shock of the black powder, but it does not explode as completely as when detonated by a blasting cap, and it is doubtful if any real benefit is obtained. Different explosives have such different rates of detonation that it is not only wasteful but frequently dangerous to use this method of blasting.

Beware of Frozen or Chilled Explosives

"Don't use frozen or chilled explosives." Although frozen dynamite is more difficult to detonate with a blasting cap than when it is properly thawed, it is more sensitive to other kinds of shock. Before low-freezing explosives became as generally used as they are today, a number of accidents occurred when men broke the frozen cartridges in two or rolled them to break up the frozen crystals. In loading well drill-holes with large-sized cartridges, a number of thawed cartridges could be dropped into the holes, sometimes 100 ft. or more in depth, with safety. Punching a hole into a frozen cartridge is by no means a safe operation, and the fumes from frozen dynamite are more poisonous than from the same dynamite when properly thawed. In fact, frozen dynamite frequently takes fire from the blasting cap and burns up, giving off large quantities of exceedingly noxious gases.

"Don't use any arrangements for thawing dynamite other than those recommended by the manufacturer." Thawing dynamite is one of the frequent sources of accidents, or, rather, it has been, as the use of low-freezing explosives has cut down the number of accidents from this cause enormously. Manufacturers of explosives have investigated every kind of thawing device and recom-

mend only those which they know are safe. Thawing must be done slowly, at a relatively low temperature, and no part of the explosive should be exposed to any temperature higher than that which can be comfortably borne by the hand. It should not be heated on stoves or on hot rocks or metal, or placed on top of a steam boiler, or over any steam or hot-water pipe, or over heated metal surface. The warmer dynamite becomes, the more likely it is to exude, and a drop of nitroglycerin falling a few inches on a heated metal surface may explode. For this reason the radiators or coils in a thawing house should always be over or to one side of the dynamite, and never directly under it. It is often a great temptation to thaw dynamite by putting it directly on top of the radiator, but this is an exceedingly dangerous operation, and radiators should be fenced off so that it is impossible to do this in the thawing house. Explosives should never be taken into or near a blacksmith shop or forge, as the flying sparks are likely to ignite or to detonate them.

Prompt Use of Thawed Dynamite Recommended

"Don't allow thawed dynamite to remain exposed to low temperatures; use it as soon as possible." Blasters often attempt to use explosives which have become chilled or partly frozen, and when remonstrated with say that the powder has been thawed. For this reason, they are urged to use the dynamite as soon after it has been thawed as possible and to take precautions against it freezing again after it leaves the thawing house.

"Don't paint magazine roofs black." On a bright summer day the temperature directly under the roof of the magazine, especially if the ventilation is poor, may rise to as high as 130 deg. This may cause the dynamite to leak, and the waterproofing on fuse and electric blasting caps to run, so that they will not only not be waterproof, but they will not carry the spark or explode. For the same reason, high explosives, fuse or detonators should not be exposed to the direct rays of the sun longer than is necessary. Sunlight tends to decompose nitroglycerin, as well as to cause it to leak if it becomes too hot.

Precaution To Be Observed in the Use Of Blasting Caps

"Don't allow priming (the placing of a blasting cap or electric blasting cap in dynamite) to be done in a thawing house." A separate place should be provided for the operation of priming, so there will be no temptation to use the magazine or thawing house for this purpose. The Park Avenue explosion in the first New York subway excavation was probably due to failure to observe this precaution. "Don't prime or connect charges for electric firing during a thunder storm." A number of accidents have occurred from lightning exploding charges connected for electric firing, not only in the open but in tunnels where leading wires have crossed the rails and the rails have been struck by lightning. "Don't carry blasting caps or electric blasting caps in your pockets." In the first place, the blasting caps are likely to accumulate moisture, in which case they may set fire to the charge instead of detonating it, or become filled with foreign matter, in which case they will not explode from the fuse, and, finally, they are too dangerous and sensitive to make this a safe practice; besides which, they are likely to fall out, become lost and turn up again at an inopportune moment. "Don't attempt to take blasting caps from the box by inserting a wire, nail or other sharp instrument into the caps," and "Don't try to withdraw the wires from an electric blasting cap." The explosive charge in blasting caps is extremely sensitive, as mentioned before, and a box of blasting caps has enough potential explosive force to blow a man in two. The proper way to remove one cap from a box is to tilt it over slightly until a few caps slide part way out, and then withdraw one of the caps with the fingers. "Don't fasten a blasting cap to the fuse with the teeth or by flattening with a knife—use a cap crimper." Crimping caps with the teeth is a common operation, but aside from the danger of biting the shell down on the fuse, it does not make an efficient crimp, and the fuse may come out or moisture get in. The cap crimper is a tool made specifically for this purpose, and it should always be used. "Don't keep electric blasting caps, blasting machines or blasting supplies in a damp place." All of these accessories are either spoiled or their life and usefulness are materially abbreviated by damp storage. A blasting machine which is kept in a dry place will be twice as effective as one not kept dry, and the same is true of blasting caps.

Manner of Wiring

"Don't leave the leading wire connected to the blasting machine." To make assurance doubly certain, it is not a bad idea to carry the blasting machine with one if it is necessary to return to the charge; then it is possible to be sure that nobody has tampered with it or will attempt to fire the charge while one is in the danger zone. "Don't loop or tie wire connections. Scrape the ends of the wires clean and bright and twist them tightly together." In mines where there is much acid water or corrosive gases, it is worth while to have all the blasting-wire connections soldered, as a number of misfires have been observed from connections, which were originally well made, becoming so corroded as to fail of their purpose.

"Don't insert blasting cap or electric blasting cap in explosive cartridges carelessly. Have closed end of detonator point toward the bulk of the charge, and have it tied to the cartridge securely." A large proportion of blasters using electric blasting caps punch a hole diagonally through the side of the cartridge, insert the detonator and take a half hitch around the cartridge with the wires. If the hole is punched through the cartridge at too great an angle, it is likely to go through the cartridge and possibly jam in the bore hole. This would probably lead to a fatal accident. The detonator should lie as nearly as possible in the central axis of the dynamite cartridge, although a slight angle does no harm, provided the end of the detonator is well inside the cartridge. The object in having the detonator point toward the bulk of the charge is that the greatest effect of the detonator is from its loaded end. If the detonator points away from the bulk of the charge, unexploded powder may be deposited in the bottom of the hole and afterward cause trouble. The detonator should always be tied or fastened securely to the cartridge, so that there is no danger of its pulling out when the charge is loaded and tamped. Otherwise unexploded powder or misfired holes may result.

"Don't store or transport blasting caps or electric blasting caps with high explosives." High explosives by themselves are fairly insensitive to shock and will withstand an extraordinary amount of rough treatment at times without exploding; whereas detonators are extremely sensitive both to shock and to sparks, and though they are violent in their explosion, effects are local. When they are carried in the same receptacle or transported together there is established a condition combining the sensitiveness of the caps with the far-reaching force and violence of the high explosive. The rule against storing or transporting blasting caps with high explosives is a particularly necessary injunction, and, unfortunately, it is often largely disregarded in mines and quarries where the powder man carries a box containing twenty or thirty pounds of dynamite with a box of caps or a bunch of primers on top of the dynamite.

"Don't attempt to use electric blasting caps with the regular insulation in very wet work. For this purpose secure 'waterproof' or 'submarine' electric blasting caps." This does not necessarily apply where only one shot is fired at a time, but where several shots are fired there is a possibility of electric leakage and short circuits through the ground to the electric blasting cap wires. This results in the under holes and those adjoining going off and the holes in the middle of the line missing fire. "Don't use old or broken leading wire or connecting wire." Broken wires are prolific sources of misfires and failure to get the shot off at the time desired. Breaks inside of the insulation are not easy to detect, and the use of wire that may contain broken sections or strands often costs much more than would new material.

Effect of Temperature on Fuse

"Don't handle fuse carelessly in cold weather, for when cold it is stiff and breaks easily. It should be warmed slightly before using." "Don't store fuse in a hot place, as this may dry it out so that uncoiling will break it." The waterproofing material on fuse is a compound of various asphalt tars with guttapercha and similar substances which become brittle in cold weather and which also are likely to run if subjected to too high a temperature. It is well worth while to store the fuse, at least immediately before its use, at a temperature between 60 and 80 deg. F. If the fuse is too cold it may crack when uncoiled and cause a misfire or a hang-fire, with its resulting danger, or, if stored in too hot a place, it is likely to go out and cause a misfire.

"Don't lace fuse through dynamite cartridges, and don't place several slit or broken cartridges on top of primer with cap and fuse. This practice is frequently responsible for the burning of the charge." The paper shell of the dynamite cartridge is sufficient protection against the side spit of the fuse from igniting the dynamite inside the shell. Without this protection the side spit is almost sure to ignite the dynamite, which will burn much more rapidly in a bore hole when strongly confined than it will in the open, sometimes causing the loss of a considerable proportion of the charge, besides giving off poisonous fumes and possibly blowing out the tamping and so making the explosion ineffective.

"Don't expect explosives to do good work if you try to explode them with a detonator weaker than a No. 6." The use of modern low-freezing ammonia dynamites has resulted in an immense reduction in the number of accidents, as those explosives are less sensitive to shock and friction than those in general use 20 years ago. At the same time, these explosives require a much stronger detonator to develop their full power then did the older type of explosives. Although it is possible under favorable conditions to detonate even these modern explosives with weaker detonators than a No. 6, there is a considerable factor of safety gained by using the stronger caps. They not only insure complete detonation, but increase the effective power of the explosive and reduce the amount of noxious fumes to a minimum. Explosives which have been stored for some time under adverse conditions become more insensitive, and a larger detonator tends to offset this condition to a considerable extent. Strong detonators will fire larger charges than weak ones, and they not only reduce chances of misfires, but almost entirely eliminate the chance of a properly primed charge burning instead of exploding. No. 6 or stronger detonators are required for all "permissible" explosives which are not "permissible" unless the strong detonators are used.

Amenities in Mine Villages

By C. J. Fuetter
Van Lear, Ky.

In every mine village covered water-tight garbage cans should be provided, each for the use of four families where these live close together. Tenants should be made to understand that all old cans, bottles, rubbish and garbage should be placed in these receptacles where the flies would not have access and from which odors could not escape. In warm weather the material thus deposited should be hauled off at least every other day to some place far away from the camp. There it should either be burned or buried. Hogs and chickens should not be kept in a mine village, as they cannot fail to be nuisances. Cows on the other hand are desirable property around a mining town, if proper care is taken to remove the manure piles regularly.

Round the drift mouths today the ground is too often bespattered with waste carbide. It is not unhealthful, but certainly not sightly. A box might be provided for the emptying of the spent carbide, and barrels of water could be placed nearby so that miners who went to charge their lamps with water could be accommodated.

Who's Next for a Shot at the Kaiser?

Resuscitated After Long Treatment

RESUSCITATION requires, from first-aid men and doctors, no little perseverance and unswerving faith. It is easy to become discouraged with the failure of the injured man to respond to the efforts made in his behalf. An instance of painstaking treatment and painful doubt, with final success as a result of continued effort, is furnished by the record of the first-aid team which aided Joseph Gemmel, who was smothered in a rush of coal and water at the Morea colliery of the Dodson Coal Co. on Nov. 5, 1917. The final successful result was highly creditable to the medical department and to the first-aid men of that corporation.

On the morning of the day mentioned, Gemmel and his "buddy" went to work in their breast off No. 4 Rockhole on the East Skidmore gangway, first level. The place had been idle for a few days because of the heavy rains the week before.

His buddy, being out of the way of the rush, called to Gemmel, and receiving no reply, came down to investigate. When near the bottom of the manway he found Gemmel covered up and called help from the next breast. Sending word to the slope bottom about the accident, the men began working the injured man down to an electric locomotive which was under the chute at the time. A nephew of Gemmel's, who was working with the other men at the rescue and resuscitation of his uncle, finally got some response to the efforts he made to enable the injured man to breathe. By this time the first-aid men, who had lost no time in responding to the call, were on hand. Taking hold of the case, they were able, by long-continued effort, to do much in helping in the work of resuscitation. Later the injured man was moved from the gangway to the hospital, which was some 2000 ft. away, and there effective work was done for several hours.

Dr. Frank Conahan, the company physician, meeting the men on the way out was on hand to take charge of the work in the hospital. The doctor and first-aid men worked for three hours before the patient began to show any favorable signs, and two more hours were spent with him before he could be removed to his home in Morea. One of the accompanying illustrations shows the doctor and the men working over the injured man in the mine hospital.

The hopes of recovery were small for a long time, but by sticking to the job and putting forth every effort the doctor and men were successful in saving Gemmel's life. In the work of resuscitation the Schaefer, or prone, method was used, and at times the doctor administered oxygen to the patient. The quick response to the call at the time of accident was one feature for praise, and it aided greatly in securing the final favorable result. Gemmel was the oldest miner in the village, having worked at Morea colliery for thirty years.

Our Great-Hearted Coal Miners*

By HORTENSE FLEXNER

THE miner understands necessity. He understands it in a face-to-face and personal way. Because he is familiar with danger, and because he has seen men hurt, he is ready to give and give again to the Red Cross. It is part of his code that a need must be met. If a man is injured in the mine, a "paper is taken" for him. Somebody goes round with a slip of paper and the men sign up for the amount of money they can give the family, until the bread-winner is able to work again. It is an old custom, many years older than the war. It has grown out of the miner's recognition of need—human need. Today the Red Cross is "taking a paper" for the men in France. And the miners, great-hearted people, gentle, with lonely eyes that can visualize human suffering, are pledging their strength to meet the need.

"I'M WILLIN' to give anything but what it takes fer the bare necessities. They need it. Us fellows kin have what we want. They take what they git." It was a long speech for the big, slow giant of a miner, stopped at the entrance of an east Kentucky coal mine, with the lamp in his cap still burning and the black powder of the coal on his face and chest. He was telling why he had given the wages of a day's labor to the Red Cross during the last drive.

"They need it," he said with large finality, speaking unaware for hundreds of heavy-muscled, silent men like himself, working alone, day by day, "fighting the face of the coal like it was a Prussian"—and thinking.

"We give 'em a day," said an older man, with a son in France. "Thur ain't no tellin' how many they give us—mebbe all they got."

Another man, grimy, embarrassed at being questioned, braced a big hand against the wall.

"A day ain't enough," he brought out slowly. "I'd give a day a month to the Red Cross. So would all the boys."

"Did the men get out as much coal on Red Cross Day as on other days?"

"As much? More! They kept a-thinkin' who it wuz fer."

There is always something personal in the references of the miners to the army. "They," with a wave of the hand to indicate far places, "the fellows," "the boys"—never the soldiers. To the miners, the men in France are intimates, friends in danger, doing the day's work, "takin' what they git." There are no camps in the mountains, no uniforms, very few war posters. The military atmosphere is lacking. But in no place could there be a keener appreciation of the meaning of the war, or more vivid realization of what the men in the trenches are living through.

The success of the second Red Cross drive in the mining section of Kentucky was due to three chief causes: the inborn and stiff-necked loyalty of the mountain people to the Government; to the excellent plan of work and education mapped out in the office of the State War Fund by J. R. Downing, campaign manager, and S. W. Calder, executive secretary. The third and very important factor in the success of the drive was the chapter war fund managers, the men and women of the isolated mountain counties who went from mining camp to mining camp, town to town, spreading the word of the Red Cross.

The result of the drive is not wholly known at this writing. But this is known. The nine separate coal divisions of the state totaled more than $200,000. Counties far up in the hills, remembered chiefly because of the long blood feuds of the mountaineers, exceeded their quotas many times. In the most remote places, beyond the railroad, the Red Cross flag hangs in the windows of tiny log cabins and country stores; it stands above the noisy coal tipples, where the little cars from the mine run straight down the mountains to dump the coal in freight cars; and in some camps, it shows above the black mouth of the mine itself. The word has been spread.

Harlan County, for the most part mining camps and very small towns, raised six times as much money as it was asked for, giving $43,000 instead of $7500. Bell County contributed $42,000, though its quota was $15,000. Perry County ran far ahead of its allotment and Crittenden, which yields fluor-spar, gave a carload of that to the Red Cross, instead of coal. Rivalry between counties was keen, as it was keen between individual workers, everybody doing his best, remembering "who it wuz fer." In the west coal section the operators gave the coal and the miners their wages.

The plan developed by the State War Fund office to interest the miners originated with Mr. Calder, who suggested that the miners be asked to give a day's labor to the Red Cross and that the operators be asked to duplicate whatever the men gave. This seemed a difficult proposition at first. For one thing, the miners were prejudiced against the Red Cross. When the last strike was settled a clause was inserted in the agreement, providing that every miner who stayed away from work without lawful excuse should be fined one dollar for every day's absence. The fine, which had to be given to some impersonal good work, was given to the Red Cross. But the men did not like the fine, and their dislike spread to the recipient of it. A man who was fined would say, in no friendly spirit, that he had been "red-crossed."

To change this impression the State War Fund office secured the aid of Major Gledhill of the British Army, Colonel Perowne and Captain Harris. These men had "been in the war," and had been wounded in battle. For two weeks they stayed in the mountains, going from camp to camp, talking to the men, telling straight facts. In the end the miners were won. When Mr. Downing sent out a pledge card asking the question, "If you knew that a day's pay would save a life, would you give that day?" the men answered "Yes."

Next, the operators were visited and consulted about duplicating the men's wages. One by one they agreed. Placards were sent out to the mines and the men made

John S. Prater, a medal miner at the Te Jay Mine, who is "a little old to fight"

Linnis Lasley won the third medal for Bell County by doing his "best on Red Cross Day"

Virgil Moore earned $25.56 on Red Cross Day. He stands ready to "back up the fellows in France"

Henry Beaute, a Red Cross worker for Harlan, mined twenty-two dollars' worth of coal on Red Cross Day

F. D. Perkins, Superintendent of Schools at Harlan; and Bud Chambers, who gave $28.50

IN THE COAL REGIONS OF KENTUCKY

The miners, great-hearted people, gentle, with lonely eyes that can visualize human suffering, gave each the wages of a day's labor to the Red Cross

ready to do a hard day's work for the Red Cross. In several counties medals were offered as prizes; in others, flags. The mines in the west section gave the men a day's rest before May 21, so that the results should be the best possible.

The amounts earned by the men on Red Cross Day varied according to their strength and the vein of coal. The fact that the coal is cut out by machine and only loaded on cars by the men, makes it possible for them to load thirteen, fifteen, sometimes twenty and twenty-five cars a day. For each car filled the miner receives $1.

James Bullins did a record day's work for the Red Cross in the mine of the Pioneer Coal and Coke Company at Kettle Island. This mine is in Bell County, and it was organized by the Rev. J. Wood Browning, of Pineville, a worker who understands the men, the mines and the need. Bullins won the gold medal in the county, earning $17.32 on Red Cross Day.

"Yes, I did my best for the Red Cross," said James Bullins, coming out of the rain into the superintendent's office. He is a tall lean man, perhaps thirty-five, with fine blue eyes looking strangely bright, because of the black dust all over his face and beard. "It wuzn't nuthin' to do. Why wouldn't I? If we lose, we ain't got nuthin' nohow." Another miner who had won second prize, John Butler, whose earnings amounted to $15.78, appeared at the door. Butler has a boy in France.

A MOUNTAIN HOUSE. THE RED CROSS SHOWS IN THE WINDOWS OF MANY LOG CABINS LIKE THIS ONE

"I had a helper that day," said Butler. "I wanted to take out all I could. I felt like I was a-doin' it fer the boy."

"Pretty hard work, isn't it, loading fifteen cars of coal?"

"Yes, it's hard. But it ain't nuthin' to what they're doin' fer us. An' the coal is needed. I'm willin' to give a day whenever they ask fer it."

The superintendent came in, J. N. Woolum. "The men liked the idea of Red Cross Day right away," said Mr. Woolum, "it wasn't forced on them. It was their affair to accept or refuse. Not a man refused."

Linnis Lasley won the third medal. Lasley is a great-boned fellow with slow, kind eyes.

"I got out all the coal I had. I would have loaded more, but I had to wait for the machine to cut more coal. That took up the time. I wanted to do my best on Red Cross Day. The boys need it. If we could see over there, I reckon it would look mighty bad."

There were men, however, in some of the mines who refused to work for the Red Cross. When they refused, they did not realize just how the other miners would "take it." Bud Chambers, of the Lick Branch Mine at Coxton in Harlan County, told how one of these men was treated. Chambers, incidentally, earned $28.50.

"One fellow threatened to give only five dollars," said Chambers. "We told him we'd drag him out, and he changed his mind. But they did drag some out at Straight Creek. There was a single man there who said he wouldn't give a cent. That was beforehand. When the day came, he did just what everybody else did. I guess he knew how we felt. If he hadn't worked, we made it up to take a collection and give him the money for the Red Cross."

Bud Chambers is an ex-marine and feels keenly about the war. He paused a minute and went on.

"But a man who'd be a slacker would be it one place as well as another. You can't make a fellow do good work if he don't want to. I believe in standin' 'em up against a wall and shootin' 'em down."

In some of the mines, the companies found it necessary to take out the men who had "turned down" the Red Cross and move them to other locations. The feeling ran so high that the loyal miners refused to work with them. Three weeks after the drive a man came to the chairman with a day's wages. The men had refused to work with him and, though he was so late, he was forced to give his share.

"The men don't forget," said Virgil Moore, a great tall fellow, who earned $25.56 on Red Cross Day. "If a man ain't ready to back up the fellows in France, something is wrong with him, and mighty wrong."

Harlan County was organized for the Red Cross by F. D. Perkins, Superintendent of Schools, and every corner of his district was reached. As one of the miners put it, "Thur can't no pro-German stay in Harlan." Mr. Perkins began his work two weeks before the drive,

WASH DAY ON THE CUMBERLAND, IN THE HEART OF THE MINING DISTRICT

getting in touch with men and operators. He did not limit the idea of giving the day's work to miners, but extended it to all "earning people," including physicians, lawyers, teachers, clerks, and postmasters. Every business house in "Harlan Town" was asked for its profits on that day and not one refused. Bulletins were published during Red Cross week announcing returns, and everybody watched the big Red Cross thermometer, where the mercury crawled up and up.

The Harlan Gas Coal Co. was one of the mines where everybody "did his best." The women in the mining camp were as keenly interested as the men and one of them, standing in her door-way with some five or six children about her, said:

"I wanted my man to take out all he could. We kin spare it. When people is sick and when they is hurt, it ain't no time to stand back." The cabin had two rooms at the most, and a man's earnings must have been useful every day. But the mountain people do not "stand back" when it is not time to "stand back."

Henry Beaute is one of the big "Red Cross fighters" for Harlan. But at first he worked under difficulties. This was because one night he made a statement that somebody interpreted wrongly. Beaute was arrested as a pro-German, tried and released. But his feelings were outraged and he went to Mr. Perkins, to ask to be used in some special way on Red Cross Day, to prove his loyalty. Mr. Perkins gave him the pledge cards which the miners were to sign, and Beaute proved that he was in earnest by getting every man at Tway to sign.

"I wanted a chanst to show 'em," said Beaute, "and I did. One thing that made me work so hard, though, was because they claimed the Gov'ment needed the coal." (Beaute got out $22 worth of coal on Red Cross Day.) "Besides," he said, "I asked every man to give—the men workin' on the outside. I proved I wasn't no German."

He stopped a minute and went on. "I'm goin' to git in this fight yet. They ben showin' pitchers uv the Kaiser in this town and I seen 'em. The Kaiser's pitcher gits in my blood. Hit makes me so mad I throw the coal plum over the cars. The Kaiser and his gineration are goin' to be killed out."

At Te Jay one of the big mining camps, and one of the most beautiful, is located. The hills are all around, and the little houses at the foot of them are well built and well cared for. The Commissary is a real department store and is managed like one. The Balkan Mine at Te Jay won the silk flag in Bell County for its contribution of $2100.

John R. Prater, one of the men who won a medal, explained his motive.

"We'd never done much fer the war down here, an' we wanted to help the Gov'ment. I'm a little old to fight, but I ain't no better than them as is gone, and when my turn comes, I'll go."

John S. White, financial secretary of Local Union 3323, worked day and night for the drive.

"I told 'em," said White, "that if they think it's nice to work eight hours and go home, they ought to think of the fellows who can't. Us miners are at the bottom of the war. We feel proud of our task and we are going to take out coal as long as the country needs it."

[The writer declares the operators duplicated the gifts of the miners and in a sense that is a correct statement. The operators actually gave the Red Cross the difference between the selling price of the coal and the labor cost of running the mine for the day.—Editor.]

Meeting of National Safety Council

WITH the motto "To adequately support our army abroad we must conserve our man power at home —we must prevent accidents in the industries of America," the National Safety Council will hold its seventh annual congress at the new Hotel Statler, St. Louis, Mo., the home of the former president, Arthur C. Morey, who is this year the chairman of the committee on arrangements. The meeting is being held before the Liberty Loan drive because the safety engineers of the United States are the most important agents in the sale of those Liberty Bonds which are to make the world safe for democracy and decency. They had to get their meeting out of the way for their loan campaign, which will commence Sept. 28. The special committee meetings will be held on Sunday, Sept. 15, from 10 a.m. till 4 p.m. The morning of Monday, Sept. 16, will be devoted to the annual meeting for all members, the address of welcome being made by Mayor Henry W. Klein, of St. Louis, and the response by the president, David Van Schaack, who also will make his annual address. Reports of officers will follow. At the afternoon session the following addresses will be delivered:

"Democratization of Industry," by Charles M. Schwab, Emergency Fleet Corporation, Philadelphia, Penn.

"Personnel Problem in Industry."

"Nationalizing the Safety Idea," by George Ring, Jr., president, Advertising Men's Club of St. Louis, Mo.

"Economic Value of Health of Industrial Employees," by Dr. Thomas Darlington, former chief of Department of Health, New York City, now of American Iron and Steel Institute, New York City.

Safety address reproduced phonographically.

Motion picture film entitled "Why," presented by the United States Steel Corporation.

The phonographic safety address is to exhibit how "canned" addresses can be delivered (in a foreign language, if need be) to mine workers and others. It is an attempt to solve the difficult language question and to meet the problem of the man who has no oratorical talent at his operation and cannot obtain any.

On Monday evening, at 8 p.m., a public mass meeting will be held at the Odeon, 1042 Grand Ave., St. Louis, Mo., for which the following items are listed:

"Safety as an Asset in Winning the War," by Franklin K. Lane, Department of Interior, Washington, D. C.

"Safety in Warfare," by H. W. Forster, general manager, Independence Bureau, Philadelphia, Penn.

New York Central Railroad Co.'s Safety Film, "The Rule of Reason."

On Tuesday morning a general session will be held from 9:30 till 12.

"The Real Problem of the Safety Engineer," by Charles R. Hook, vice president Operating Division, American Rolling Mill Co., Middletown, Ohio.

"How to Organize for Safety," by Frank E. Morris, safety engineer, American Rolling Mill Co., Middletown, Ohio.

"Modern Methods of Safeguarding," by J. J. Heelan, superintendent Bureau of Inspection and Accident Prevention, Aetna Life Insurance Co., Hartford, Conn.

"Does the Attitude of the Foreman Determine the Success of the Safety Engineer?" by W. E. Worth, general superintendent, Chicago Tunnel Company, Chicago, Ill.

Safety address reproduced by phonograph record.

The Local Councils will hold at the same time a meeting of officers and committeemen at which their problems will be discussed. The Chemical, the Woodworking, the Foundry and the Employees Benefit Association sections will hold separate meetings. In the afternoon, from 2 p.m. to 5 p.m., there will be a general round-table discussion on "How To Sell Safety to the Big Boss," and "Promotion of Community Interest in Safety as an Industrial Asset." There will also be meetings of the Health Service, Public Safety, Steam Railroad and Women's sections. On Wednesday, besides the meeting of the Mining section, there will be a meeting to discuss employees' benefits and others for the consideration of safety in construction work and in relation to the iron and steel, public utilities, steam railroad and woodworking industries. A session will also be held of the Public Safety section. In the evening an informal dinner will be held at which President Woodrow Wilson will deliver a five minute address by long distance telephone; R. M. Little, director of the American Museum of Safety, will speak on "Forethought vs. Afterthought in Safety," and James Schermerhorn, the editor of the *Detroit Times*, who so pleased the audience who heard him at Detroit when the convention was held in that town, will deliver an address entitled "The First Set of Fours." Miss Jane Addams, of Hull House, Chicago, Ill., will conclude the evening with some remarks on "The New Place in Industry that the War Has Given to Women."

Thursday will have meetings not only of the Mining section, but of the sections devoted to safety in the electric railway, iron and steel, paper and pulp, cement and textile industries, and to the relation of the Government to safety and employment.

On Friday the automotive, car builders, iron and steel and paper and pulp industries hold sectional meetings. With these the congress closes. There will in all be 174 speakers.

The Mining sessions are given in full as follows:

Wednesday, Sept. 18, 1918

1. Report of Chairman.
2. Report of Secretary.
3. Reports of Committees.
4. Appointment of Nominating Committee.
5. Addresses:

9:30 a.m. "Hazards and Safeguards in Coal Break-

ers and Washeries," by D. K. Glover, Lehigh Coal and Navigation Co., Lansford, Penn.

10:00 a.m. "Is the Experienced Miner More Liable to Accident than the Inexperienced?"

10:30 a.m. "What Relation Has Labor Turnover to Mining Accidents?" by Robert Johnson, Pittston, Penn.

11:00 a.m. "Safety Work in Metal Mining from the Employees' Standpoint," by Edwin Higgins, California Metal Steel Producers' Association, San Francisco, Cal.

11:30 a.m. "Hoisting Ropes," by M. W. Reed, American Steel and Wire Co., Worcester, Mass.

2:00 p.m. "Standardization of Mine Cars in Metal Mines," by Prof. R. M. Raymond, School of Mines, Columbia University, New York City.

2:30 p.m. "Acetylene and Electric Cap Lamps from a Safety Standpoint," by H. M. Chance, Philadelphia, Penn.

3:00 p.m. "Suggested Methods of Keeping Mine Accident Records; Results Which Have Been Obtained," by A. H. Fay, Mine Statistician, United States Bureau of Mines, Washington, D. C.

3:30 p.m. "Hazards in Ore Dressing Plants," by J. S. McKaig, New Jersey Zinc Co., Franklin, N. J.

4:00 p.m. "Handling and Storing of Explosives," by Arthur LaMotte, Manager Technical Division, E. I. du Pont de Nemours & Co., Wilmington, Del.

4:30 p.m. Discussion.

Thursday, Sept. 19, 1918.

9:30 a.m. "Practice of Mine Ventilation," by C. A. Mitke, Assistant Consulting Engineer, Phelps-Dodge Corporation, Bisbee, Ariz.

10:00 a.m. "The Dust Hazard to Health in the Stone Industry," by F. L. Hoffman, Statistician and Third Vice President, Prudential Life Insurance Co., Newark, N. J.

10:30 a.m. "The Effects of the Use of Pneumatic Tools on the Nervous System," by Dr. F. M. Barnes, Jr., St. Louis, Mo.

11:00 a.m. "Abatement of Dust from Drilling Operations by the Use of Water Drills," by W. O. Borcherdt, superintendent, The Bertha Mineral Co., Austinville, Va.

11:30 a.m. Report on Standardization of First-Aid Methods, by Lt.-Col. C. H. Connor, American Red Cross, Washington, D. C.

Careful Records Reduce Mine Accidents*

By ALBERT H. FAY
Assistant Statistician, United States Bureau of Mines, Washington, D. C.

WHEN, in 1911, the United States Bureau of Mines began the collection of mine-accident statistics, there were but few data available concerning the nonfatal injuries in the mining industry. Even the reports of fatal injuries were not so complete as they should have been, but regarding them sufficient data had been accumulated to enable us to point out the principal hazards. The returns, when first received and published, showed what was then considered a high rate for nonfatal injuries, for at that time there was nothing with which to compare it. In about 1911 the first efforts were made in the movement which caused the industrial accident commissions to be legislated into existence. The mining companies had not been accustomed to keeping complete records for either the state or Federal Government, and in many cases not even for their own use.

The recording of all accidents is absolutely necessary if there is to be a reduction in the casualty list at mines. Detailed records will give the exact cause of the accident, and knowing this, in most cases remedies will readily suggest themselves. Records furnish the safety engineer a reliable mass of data about which to formulate ideas relating to safety, safety devices and safer methods of mining. To this end the bureau prepared a form for keeping a record of accidents at mines. On this form is to be recorded the name of the injured person, the date of the accident, the cause, also whether or not it was fatal and also the degree of disability, due to the accident, measured in days lost. A number of the mining companies are keeping this record, and the returns which have been received from these companies indicate that the tabulations are being kept more carefully now than in the past. At the same time they show an increase in the number of nonfatal accidents, but this is more apparent than real, as the industry is no more dangerous than when records were not kept. The record simply brings to light the hidden dangers of a great industry.

The accident rates at mines as heretofore published also appear lower than they actually are, by reason of the fact that in so many instances the operator reports the total number of men whose names appear on the payroll during the year. By reason of the annual labor turnover, the number of men on the payroll is much larger than the actual number of full-time workers, hence in order to get true accident rates it is necessary that the time during which the men were employed be known. Such a record of the hours worked has been kept by the New Jersey Zinc Co., thus placing the accident rates on a basis regarding the exactness or completeness of which there can be no doubt.

The next best step to adopt was to reduce all accidents to a 300-day basis. This, however, does not take into account the 8-hour or 10-hour day, but in most of the metal mines, in recent years, the 8-hour day has prevailed. Many of the inequalities have been eliminated by reducing the figures to a common denominator of 300 days. This, however, does not eliminate the payroll discrepancies, when the number of men employed is given as per total on payroll.

The increasing completeness of records is due in part to the bureau's campaign among mining companies for safer conditions and in part also to the annual requests made to them for reports of accidents during the current year. The enactment of accident-compensation laws is another important cause. The mining companies expect to make returns, and the majority of them, therefore, are now keeping records so that they

*Abstract from an article "Results Obtained by Keeping Mine Accident Records," to be read before the Mining Section of the National Safety Council at St. Louis, Mo., during the Seventh Annual Congress, September, 1918.

may be able to render their report at the close of the year. There is, however, some lack of uniformity as to what injuries they shall record, although it is believed that the larger companies are recording practically all injuries. The accidents which are reported to the bureau are only those which cause disability of one day or more. We do not expect accidents causing a disability of less than one day to be reported, although in some cases it is believed that they have been included.

A recent paper prepared by B. F. Tillson, on "Recording Accidents and Safety Measures,"[1] gives a detailed description of the methods used by the company just mentioned in keeping records of accidents, together with its method of determining rates for comparative purposes, and also many suggestions as to what has been done in the matter of safety improvements and the methods employed among the foremen and shift bosses to reduce accidents.

Mr. Tillson's article shows that for the first four months of the year 1913, without any special safety organization, but with complete records, the nonfatal injuries at the mines which caused any loss of time amounted to 2.24 per 10,000 hours of labor performed. The last eight months of 1913, during which safety-first was inaugurated, the accident rate fell considerably, being reduced to 2.17.

The organization was still more perfected in 1914 and 1915, with the result that in 1916 the nonfatal injury rate was 0.77 per 10,000 hours and in 1917, 0.78. By keeping detailed records, the company has been able to diagnose the principal causes of accidents and apply remedies therefor. By an educational campaign among the employees and by the giving of bonuses to the shift bosses the reduction in accidents has been marked. The records of this company not only show accidents by causes, but also by occupations; and the company also charts them according to the actual number of hours employed in the mines.

Data compiled by a large number of companies on this basis would undoubtedly furnish a reliable basis on which to study accidents and their causes, and at the same time give sufficient information to establish equitable insurance rates. Exact records should contain sufficient data to show the causes of all accidents; hazards by occupations; hazards by mining methods; the days and hours worked and the time lost per accident. This will serve as a basis for insurance rates that will be fair to all. Finally such records will show the real progress that is being made in accident prevention at the mines.

Mine Safety Appliances in Warfare

By F. H. TREGO
908 Chamber of Commerce Building, Pittsburgh, Penn.

FOR some years prior to our entry into the war, certain men were engaged in the excellent work of devising ways and means to cut down the percentage of accidents that occurred with such startling frequency among those employed in our varied industries. The individuals so engaged were styled "safety engineers," and they carried on their propaganda under the slogan of "Safety First."

The prime object of the safety-first movement is the conservation of human life, while that of war can be summed up in the word "destruction." It did not seem possible when we entered the great conflict that there could be any common ground on which the engineers of safety and the engineers of war might come together. However, as more was learned about modern warfare, and as it became more and more apparent that conservation would be a preponderating factor in the winning of the war, the door was opened whereby the safety engineer could enter and do valuable work.

To save a life wherever possible is not only humane, but at this time, when the necessity of conserving man power becomes daily more apparent, every life saved means a man more to help drive nails in the coffin of German autocracy. In this war, as in no other in history, the men who make up our industrial units—the men who make guns or cartridges, or help transport them, or dig the coal that heats the iron or steel used in their manufacture—are as vital to the success of our war program as the men who are on the firing line.

Among our "industrial soldiers" the practice of safety and the use of safety apparatus had gained great headway, but few ever thought of applying the safety-first principles learned in peace to the needs of the men in the trenches. The safety engineers did, however. They convinced the army officers that many of the things used by the industrial army behind the lines could be employed to advantage by those on the fighting line. It is the object of this article to describe briefly several of the safety devices that have been found useful for war work.

The general public will always associate the name of Thomas A. Edison with devices to entertain or brighten life. To various fields of human endeavor he has probably contributed more than any other man. To the safety movement, in which he has shown great interest, he has given the Edison electric safety mine lamp.

There are, of course, other types of electric safety lamps, but after exhaustive tests the Edison was chosen for use "Over There," and it is one instance of a specific safety device that is now being used in the trenches. Just how these lamps are employed one is not at liberty to disclose, but the fact remains that when the call came a device that had been developed and perfected by the safety movement was ready to "carry on."

Probably the most striking illustration of the development of a safety idea to meet a war need is presented by the Gibbs self-contained oxygen breathing apparatus. A few days after war was declared by the United States an officer in the War Department was asked to devote some of his attention to the question of breathing apparatus, with a view to its being used by the troops. After witnessing a demonstration of the

[1] "Engineering and Mining Journal," Apr. 17, 1917.

Gibbs device, the officer stated that he considered the time consumed in making the tests wasted, as there was no possible chance of the apparatus ever being needed abroad. Strange to relate, however, among the first requests made by General Pershing was one for hundreds of sets of oxygen-breathing apparatus.

Many people are of the belief that a self-contained breathing apparatus is simply a gas mask. Nothing is farther from the truth. The gas masks commonly used by troops in action are machines for filtering certain known noxious gases, and the wearer of the device is at all times obtaining the air he breathes directly from the atmosphere. The air is filtered by the mask in much the same manner as water is purified by passing through a filter.

There are gases, however, which cannot be so filtered, and these gases prove to be the most deadly. Carbon monoxide (CO) is one of them, but it is not what is termed by the military forces an "offensive gas." This means that carbon monoxide cannot be used as a gas for offensive purposes as are chlorine, mustard, phenylcarbylamine, phosgene, xylyl-bromide and various tear and sneezing gases now being released on the battle-fronts in Europe for the purpose of overcoming men. Carbon monoxide is a little lighter than air, and as soon as it is released passes off into the atmosphere. It cannot be held in clouds as are other gases, and therefore is precluded from use for offensive purposes.

There are numerous places, however, where troops do come in contact with carbon monoxide. These accumulations of gas are found in pill boxes, machine-gun emplacements, and in dugouts where heavy artillery is being fired from cover. In spots such as these the air becomes saturated with the poisonous gases, and the men who are forced to breath this air rapidly succumb.

Gibbs Self-Contained Breathing Apparatus

To overcome these conditions there is only one known safeguard—a self-contained breathing apparatus—and the Gibbs machine was chosen by the Government because it was found to meet all requirements. The wearer of this device obtains his air supply directly from the apparatus and not from the outside atmosphere. By an ingenious arrangement of valves, tubes and chemicals the air exhaled by the user of the apparatus is purified, cooled, and fed back to him. The apparatus can be used from two to ten hours without being taken off for recharging.

The United States Bureau of Mines, in conjunction with some well known safety engineers and physiologists, experimented for a number of years on an apparatus that would supply oxygen in proportion to the wearer's needs. It is a most noteworthy achievement of the Bureau of Mines and of the engineers referred to that a machine with this characteristic was perfected in time to answer General Pershing's call, and that within a short time a strictly American self-contained breathing apparatus—the Gibbs—was shipped to him in the quantity he desired.

Another of the inventions of the Bureau of Mines which has proved of service at the front has been the gas detector invented by George A., now Colonel, Burrell. It will indicate and record the percentage of combustible gas even when it occurs in a proportion as low as 0.2 per cent.

To the average person a stretcher on which to carry a wounded man would be deemed a simple device capable of very little improvement. Yet a new type of stretcher was called for by army officers to meet certain every-day conditions in the trenches. All the known makes of stretchers were submitted, but none would answer the purpose. The problem was finally referred to a prominent safety engineer who happened to be in Washington when the matter was being discussed. He was asked if he knew of anything that would meet the requirements. He said he believed he did.

Away out West, thousands of miles from Washington, at a gold mine among the Black Hills, this engineer had seen a stretcher in use which he was positive would prove to be the type so anxiously sought. It had been made at the mine after plans drawn up by the safety department. Telegrams were exchanged, and to the credit of the management of that mine it should be stated that within three hours after the receipt of the first telegram the only stretcher possessed by the mine was speeding on its way to the War Department. When the stretcher arrived in Washington it was subjected to a rigid test and accepted. Today hundreds of these stretchers are in use at the front, thanks to the Homestake Mining Co., of Lead, South Dakota.

Important to Conserve Human Life at Home

To this point conditions in Europe, where our cause for human liberty is being argued at the cannon's mouth, have alone been dealt with in this article. However, it is just as important that we seek the conservation of the men engaged in industrial pursuits at home if those on the firing line are to receive maximum cooperation from the industrial soldiers at home.

It is to be regretted that our casualty lists make mention only of those who are killed or wounded while engaged in battle, while nothing is said about the casualties which occur in industrial pursuits. For many years safety engineers have been trying to awaken the public conscience to the alarming number of accidents occurring in our industries each year and what they amount to as compared with the casualties of war.

Only a few figures to emphasize the need for an intensified safety-first movement can be given here, but these should be an object of just as much attention as the lists of those killed and wounded in battle. Our fatalities at home number between 30,000 and 40,000 a year, or about 125 a day. Our seriously injured total about 350,000 to 400,000 a year, something like 1000 every day. As to minor injuries, about 2,000,000 a year are reported, or about 5000 to 6000 a day.

If these injuries were suffered by those engaged in battle they would all be reported. Why not, then, some centralized effort on the part of our Government to reduce this loss at home? Our workers are soldiers, too, and just as necessary to the winning of the war as the men in the trenches.

We have our fuel administrator, food administrator, railroad director, shipbuilding program, price fixing, etc. Wherever a leak can be plugged Uncle Sam has supplied the stopper. But still the safety-first movement is not taken as seriously as it should be by those most vitally concerned. Why not a safety-first administrator, whose duty it will be to use every means available to stop the waste of life behind the lines?

Forms for Use in Recording Compensation

SYNOPSIS—*How to keep records which will stimulate foremen, assistant foremen and safety engineers in the work of safety and make it possible to ascertain the probable effect, in the cost of self-insurance, of any change in legislation.*

DURING the last few years, safety first has made great strides in all industries. Few indeed, if any, are the occupations that are more hazardous than that of the anthracite miner. Suddenly awakening to this fact, the safety-first movement has gone forward at a rapid pace, and today, it is one of the important issues in the operating department of all the larger coal companies.

For several reasons, the most potent factor in the advancement of safety during the last two years has undoubtedly been the passage of the "Workmen's Compensation Act." Before the act came into operation, few of the companies had any form of relief for their injured workmen. Those that did were more or less indifferent in their attitude to safety, and an accurate record was not attempted. As the workmen themselves contributed a portion of the funds to be expended, and as the time of compensation for injuries was limited (as were also the sums allowed in fatal cases) the yearly expenditures were small in comparison with what they are at present.

A majority of the anthracite coal companies carry their own insurance. A careful record of each case is kept, showing the actual cost of compensating the men in their employ. As a result, each month the management can see in dollars and cents, as well as in "man-days" lost, what accidents mean to the industry. At first these figures were a revelation. A study of the causes showed that by far the greater number of accidents were preventable and due to carelessness or ignorance. Through systematic education and safety devices, together with a rigid enforcement of safety rules, these causes are rapidly disappearing.

To keep an accurate account of all accidents, a practical system of handling compensation is necessary. The following is a detailed account of a method used by one of the larger anthracite companies. While to the reader it may appear cumbersome, it works smoothly and efficiently, and after much experimenting it is found to give entire satisfaction.

While the system involves much detail, it is handled with a comparatively small force and is not expensive. It also has the advantage of keeping the operation heads and the safety engineer in close touch with conditions at all collieries. It also enables them to know with exactitude the degree of safety existing in each of the many assistant foremen's districts. A record is kept both of the expense of accidents and of the labor loss. This system has resulted in reducing the average time lost per accident to a low figure and has kept the men well satisfied, as their cases are handled promptly and fairly. It has, moreover, resulted in a small percentage of disputed cases.

To make so complete a record requires a quick and elastic filing system. The only equipment suitable for this purpose is the visible index file, and this system has been adopted. When reports reach the office of the chief surgeon they are numbered consecutively and forwarded to the adjuster. The state reports are then made and the original papers kept in an individual folder. When the folder is ready for filing, a card (as shown below) is filled out, giving the employee's name, address and occupation, as well as the number of the case and the date of injury.

The card is then placed in the file in alphabetical order. Each card has a space in which the nature of the injury may be entered. The names on all cards are visible, making it decidedly easy to locate a particular case. When a man comes to the office to sign his agreement his name is asked, and he replies, for instance: "John Smith." Thereupon the clerk turns to panel "S" in the file and readily locates the "Smith" desired. Frequently two or more injured men bear the same name. This causes no confusion, as the man's identity is learned through his address, occupation and date of injury. The following forms show the use of the file and the simplicity of its operation.

Smith, James		218 W. Broad St., Lansford, Pa.			Machinist

SAMPLES OF ACCIDENT RECORD CARDS

Each accident is classified as to nature, cause and class and separately classified as occurring either outside or inside the mines. Each accident and its actual expense is entered against the foreman or assistant foreman of the district in which the accident occurred. Foremen are told each month how their district compares with others in regard to number and cost of accidents, and this stimulates them to a greater zeal for the safety of the men and aids the safety engineer in eliminating the causes of preventable accidents.

It is impossible in a tabulated statement to indicate the exact nature of all accidents incurred, but the following list has satisfactorily covered all accidents which have come under notice during the past year. It affords a knowledge of the sources of accident that is indispensable in safety work.

ACCIDENTS CLASSIFIED BY THEIR NATURE—JAN. 1 TO DEC. 31

Nature	Number	Per Cent.	Nature	Number	Per Cent.
Burns	....	4.5	Miscellaneous	....	0.1
Contusions	....	28.7	Not injured, (entombed)	....	0.1
Crushes	....	1.4	Sprains	....	7.5
Dislocations	....	0.4	Suffocations	....	0.2
Electrocutions	....	0.1	Total	....	...
Fractures	....	4.4	Non - compensable accidents	....	
Foreign bodies in the eye	....	5.8	Grand total	....	
Infections	....	4.2			
Lacerations	....	42.6			

The following table shows the accidents occurring during the year, classified as to cause, and divided between the inside and outside operations.

ACCIDENTS CLASSIFIED BY CAUSE—JAN. 1 TO DEC. 31

Cause	Inside	Outside	Total	Per Cent.
Animals	.....	.....	.....	1.4
Caught in machinery	.....	.....	.....	4.7
Electricity	.....	.....	.....	0.5
Explosion of dynamite	.....	.....	.....	0.2
Explosion of gas	.....	.....	.....	1.5
Falls of roof or sides	.....	.....	.....	4.1
Flying material	.....	.....	.....	9.8
Falling material	.....	.....	.....	22.2
Falling persons	.....	.....	.....	6.4
Handling material	.....	.....	.....	17.9
Miscellaneous	.....	.....	.....	1.7
Heat	.....	.....	.....	0.0
Rush of material	.....	.....	.....	2.5
Suffocation	.....	.....	.....	0.3
Stepping on material	.....	.....	.....	2.9
Striking obstructions	.....	.....	.....	5.4
Transportation	.....	.....	.....	9.6
Use of tools	.....	.....	.....	8.9
Total	.....	.....	.....	...
Non-compensable accidents	.....	.....	.....	...
Grand total	.....	.....	.....	...

NOTE.—Transportation in the above statement covers all accidents caused by cars, electric and steam locomotives, whether the accidents result from the bumping of cars, the squeezing of men against the rib, the running of cars over them, or from other causes.

Accidents are divided into classes, according to severity, as follows:

ACCIDENTS CLASSIFIED ACCORDING TO DURATION OF DISABILITY—JAN. 1 TO DEC. 31

Class	Inside	Outside	Total	Per Cent.
No time lost	.....	.....	.....	.....
One to seven days lost	.....	.....	.....	.....
Seven to fourteen days lost	.....	.....	.....	.....
Fifteen days or more lost	.....	.....	.....	.....
Permanent partial disability	.....	.....	.....	.....
Fatal accidents	.....	.....	.....	.....
Total	.....	.....	.....	.....
Non-compensable accidents	.....	.....	.....	.....
Grand total	.....	.....	.....	.....

The value of this report cannot be overestimated, for the actual cost of each case is available, and the whole cost of any particular class of accident can be determined. Thus it will be possible to estimate what the cost of compensation will be in case any material change is made in the "waiting period" which is provided in the present law.

There are always a number of noncompensable cases recorded. This is due to the fact that the foremen are not fully conversant with the law and are desirous to report all cases as per instructions. At first, the employees reported to the foreman injuries received outside of their employment, and also those which, while received at their employment, were sustained under conditions which would not bring them under the law.

Sometimes the employees go to the doctor's office claiming injury, but have no confirming report from the foreman. The man is told to bring such a report, and if he fails to have it on his return the foreman is interviewed and the facts ascertained. Decision is then made as to whether or not the case is compensable. When a report arrives from any colliery that is out of the ordinary, the adjuster at once goes to the foreman, gets the witnesses together, if there are any, and obtains all facts pertaining to the alleged accident.

Foreman.

The doctors are a great help also in preventing fraudulent attempts to obtain compensation. Many times where an injury is claimed a diagnosis reveals the fact that the suffering is from a constitutional disease. At times this disease is excited by a trivial injury, and this is especially true of eye cases. The employee is entitled to compensation, as he has valid proof as to its occurrence. Others have no proof of an injury and after they receive the doctor's attention the fact is established that they are attempting to take advantage of the Compensation Law. Cases of this sort are frequent.

At first many of the employees seemed to be dissatisfied with the provisions of the act, especially the 14-day waiting period. The company, whose record system is being described, continues medical treatment until the injured man is able to return to work. It was realized that the medical expenses in most cases would equal, and many times exceed, the compensation for the first 14 days. This concession of the company satisfied most of the complaints, though there is still an undercurrent of dissatisfaction on that score. Where the antiquated system of paying the doctor $1 a month for professional services and medicine for the mine worker's family is in vogue there the greatest dissatisfaction is found.

Prior to the passage of the compensation act the company, whose compensation records we have been examining, had a beneficial fund to which the employees contributed an exceedingly small percentage of their wages, and those who met with an accident were paid from the fund 50 per cent. of their wages from the date of injury until they recovered. However, no compensation was paid for any time exceeding six months, and no compensation was paid when the injury incapacitated them for work for less than six days. When the employees came to understand the workings of the compensation act and could compare it with the beneficial fund, they saw the advantages of the former.

How Cases Are Handled

The following is a statement in detail of the method used in handling cases from the time of application for employment through a period of disablement, compensation and a return to the mines.

1. *Application for Work*—A blank is filled in at the employment bureau and signed by the applicant.

2. *Physical Examination*—Signatures are compared and defects in the applicant, if any, are noted and notes of identification are taken.

3. *Industrial Certification*—Applicant is given a certificate of examination stating whether he is qualified for employment and for what special line of work he is available.

4. *Employee's Report of Injury*—When injured the employee reports at the colliery office, where a form confirming the injury is filled in and signed by the foreman. A copy is kept on file at the colliery office, one is sent to the chief surgeon, one to the adjuster, and one is given to the injured employee for presentation to the attending surgeon.

5. *Surgeon's Preliminary Report*—When the injured employee presents to the surgeon the foreman's report confirming the accident, he is given medical treatment and a surgeon's preliminary report is made out covering the nature and cause of the accident as well as an estimate of the disability and a description of the treatment. This report is then forwarded to the adjuster's office.

6. *State Reports*—From the information given on the surgeon's preliminary report the necessary state reports are made in the adjuster's office and forwarded to the State Department.

7. *Surgeon's Intermediate Report*—If the disability extends beyond the first or fifteenth of any month an intermediate report is made out by the attending surgeon. This is forwarded to the chief surgeon and by him to the adjuster. This report describes the treatment and gives the condition of the patient.

8. *Surgeon's Final Report*—When the disability ceases a final report is made by the surgeon showing when the disability ceased and the date when the injured person returned to work.

9. *Return-to-Work Certificate*—When the injured employee appears physically able to resume work he is sent to the chief surgeon's office for inspection, and there given a return-to-work certificate. This he must present to the foreman before being permitted to resume work. However, the injury received may not yet be fully healed, and the employee must report to the attending surgeon until he pronounces the injury cured.

10. *Final Report*—As soon as the injury is fully healed a final report is made. Copies of the final report and return-to-work certificate are forwarded to the adjuster's office, and the supplementary portion of the S.O.M. report having been filled out as to days of disability it is forwarded to the state.

11. *Notice to Payroll Department*—Upon receipt of the surgeon's preliminary report a notice is sent to the payroll department, provided the estimate of disability anticipates an absence from work of over two weeks. The payroll department ascertains the average weekly wage of the injured employee for the last six months or for so much of that time as he worked for the company. This statement of earnings is sent to the adjuster.

12. *Adjuster's Agreement*—The adjuster prepares an agreement and the employee, if able, goes to the adjuster's office and executes the agreement. His name is then placed on the payroll. In case the employee's disability is such that he is confined to his home or to the hospital, the adjuster takes the agreement to him for execution and prevents delay and unnecessary hardship to the dependents.

13. *Certified Copy of Agreement*—As soon as the agreement is executed a certified copy is sent to the state and a copy to the auditor, the original being kept on file in the adjuster's office. Once on the payroll the injured employee is placed on every succeeding payroll till his disability ceases. The lightly injured employee receives his compensation at the works, but if he is confined to his home or the hospital the pay of the injured employee is delivered to him wherever he may be.

14. *Receipt for Compensation*—Upon receiving final payment the employee signs a receipt for the full amount he has been paid. This receipt is forwarded to the adjuster, checked with the payroll and then forwarded to the state, thus closing the case.

15. *Adjuster's Records*—In the adjuster's office a record is kept of each accident, showing the colliery and section of the colliery where the injured employee worked, as well as the nature and cause of the accident, the name of the surgeon in attendance on the injured employee, the days that the employee was disabled, the medical cost, the compensation paid and the total expense. With this record made the case is filed and retired for future reference.

A banner bearing the inscription "Safety-First Honor District" is flown each month at the headquarters of that district which has had the lowest percentage of accidents during the month, based on the percentage of man-days of disability compared with the number of man-days worked as contained in the table below.

The form shown below is used as a detail report sheet for each colliery and also as a summary of the accidents, etc., for all districts. The report of an accident shows the place where it occurred. This is indicated by the number under the first column, headed "Section." Take, for instance, the district shown: A-1 would be "A—Colliery Outside." This shows at a glance whether the accident occurred outside or inside the mine. A-2, A-3, etc., indicates all accidents occurring inside, and the different numbers represent the sections and the assistant foremen in charge. This system permits entering each accident in its proper place directly against the foreman responsible in a sense for its occurrence.

NUMBER AND COST OF ACCIDENTS TO EMPLOYEES AND THE RELATIVE EFFICIENCY OF FOREMEN'S DISTRICTS BASED ON MAN-DAYS DISABILITY AND MAN-DAYS WORKED

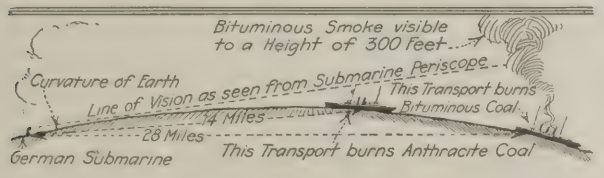
Don't Call the Miner Till You Want Him

The *United Mine Workers' Journal* calls for the complete exemption of miners so that they won't be classed as slackers when the war is over, declaring that no halfway status will satisfy the men. It says:

"The coal miners are doing their duty everywhere, in and around the mines and in and around the trenches. They can render service as great, or perhaps greater, in the mines than in the trenches. But there will come a time after the war when men will ask each other the question: 'Where were you in the war?'

"If the Government were to exempt coal miners as a body from military service each man could answer this question without hesitation, as he would have the action of the Government as justification for his remaining at home to produce coal. It would remove all possibility of criticism of any miner who did not enter military



service. But without such action by the Government there will exist a feeling that some one may point a finger at the miner and accuse him of slacking military duty.

"Thus the miner is placed in a delicate and embarrassing situation. He will work just as hard, risk his life and undergo hardships in the production of coal, and there is no reason why any criticism should be directed to him, if he remains in the mines. The Government declares that coal mining is wholly war work."

It is in the same degree war work as is shipbuilding, and men engaged in shipbuilding are not required to perform military service. It would be unjust to criticize shipbuilders for remaining out of the trenches and it would be equally unjust to direct such criticism to coal miners.

The Danger in Smoke

The submarine, while it has ceased to be a national menace, is nevertheless an ever-present danger to both merchant and transport shipping. All allied vessels escaping hostile U-boats do so by one or more of four means—defense, convoy, evasion or flight. Obviously, defense has its shortcomings. Even though the fight may end successfully for the vessel, that vessel may be

Sketch showing Curvature of Earth and Manner in which a Submarine – its Periscope being 12 Feet over Water – can discover a Transport burning Bituminous Coal at a Distance of 28 Miles; while a Transport burning Anthracite Coal cannot be discovered at a Distance of over 14 Miles. This shows that if the Miners of the Anthracite Region can supply sufficient Anthracite Coal to make Power for Our Transports, the Chance of Submarines locating Transports by the Smoke is reduced One-Half.

decidedly the worse for having met the enemy submarine. Convoy, while highly effectual, is expensive and only practical for fleets or large numbers of vessels. Evasion is, perhaps, all things considered, the most satisfactory means whereby a single vessel may escape the U-boat, since flight—that is running away—is open to the same objection as defense—the fleeing ship, although it escapes, may be the worse for the meeting.

The secret of evasion lies in invisibility. To this end various methods of "crazy" painting known as camouflage have been adopted with considerable success. All the camouflage possible, however, will not protect a vessel that makes its presence known through the emission of smoke from its funnels.

The accompanying illustration is derived from a blueprint originating with the Lehigh Coal and Navigation Co., and widely distributed in the anthracite region. This shows the advantage of burning a smokeless coal by transports and other vessels. When a nonsmoking steamer is below the horizon its presence and position are unknown to a submarine 14 miles away. If large volumes of black smoke are emitted, however, the submarine commander will be aware at a distance of 28 miles of both the presence and approximate position of the vessel, even though no part of either hull or rigging is visible.

Thus a lurking submarine may discover a smoke-emitting transport or other steamer at just twice the distance at which it could discern the same vessel if no smoke were being emitted by it. The use of a smokeless fuel such as anthracite is therefore twice as safe (if safety may be said to exist at all in waters infested with enemy U-boats) as is the use of a high volatile smoky coal.

Mine Foreman a General in the Fray

Godfrey Jones, a Welsh mine foreman, who enlisted early in the war as a private and who was nominated Aug. 27 to be a brigadier-general, was once considered by mine officials with whom he was connected for years as lacking the ability to lead men.

According to the *Daily Mail*, Jones, who is 36 years old, attended night school as a boy and finally obtained his diploma. He was appointed foreman in a mine but did not make good and was reduced to the ranks of a digger. Given another chance he succeeded.

Shortly after the war broke out Jones joined the Cardiff "Pals" battalion of the South Wales Borderers. He speedily was made corporal and rapidly rose to the rank of sergeant-major. Later he received a commission.

Jones went to France in the autumn of 1915 and soon afterward was transferred to Saloniki, where he won the Distinguished Service Order and promotion to a lieutenant-colonelcy. Three weeks ago he obtained leave to come home and marry a war hospital worker. The directors of the mining company with which he was formerly employed have decided to create a special position for him on his return to civil life.

Effect of Pneumatic Reciprocating Tools on the Nervous System

By FRANCIS M. BARNES, JR.
St. Louis, Mo.

Apparently the temperature of the mines, the manner of drill operation and its discontinuity have prevented the symptoms of the disease, if the disease actually exists from appearing in mining work. The effects appear quite temporary and are entirely confined to cold weather. They are found most frequently, apparently, in the hardstone industry. The circulation can readily be restored by friction or swinging the arms.

WITHIN the past two years complaints of the ill-effect of the use of the pneumatic hammer have been prevalent in the Indiana stone belt, although these complaints do not seem to have originated so much with the individual user of the hammer as with labor organizations of which he is a member. It has been claimed that the use of the hammer produced a diseased condition in the men using it, affecting the nervous system and even leading to paralysis, insanity and other forms of complete incapacitation.

During a careful investigation on behalf of the Bedford Stone Club auxiliary it was not found, in any instance, that the use of the pneumatic hammer produced any deleterious effects upon the general health of the workers, excepting that among hardstone workers, possibly, consumption was somewhat more prevalent though no higher than is normal for similar groups of people. In fact, it is questionable if it is as high. Limestone cutters as a class are a robust, healthy group of men, somewhat above the average in other industries.

So far as this study is concerned the men using pneumatic hammers on limestone were found to be in good general health, and none of the group examined showed any constitutional disease. Their troubles (supposedly arising from use of the hammer) were limited to a disturbance of the function of the left hand—commonly known as "white fingers," or "dead fingers." As a general thing this condition occurs shortly after the men first go to work in the morning, or until they have "warmed up," but it also occurs during cold weather when the hands are otherwise exposed.

First the little finger and the ulnar side of the left hand (in right-handed men) become pale and blanched; the same area soon giving rise to tingling or numbing sensations, sometimes even to slight pain. The ring finger and part of the middle finger may also be involved in this process. By swinging the arms or rubbing the hands the condition may be made to disappear, and when the hands are warmed the pallor rapidly gives place to diffuse flushing and reddening. The index finger and thumb of the right hand are occasionally affected, particularly in those workers who improperly control the exhaust by their finger or thumb. So far as could be determined this condition of the hands constitutes the sole trouble from which the stone workers complain insofar as the use of the pneumatic hammer in their work is concerned.

The fact that the trouble, when present, preëminently affects the left hand (which holds the chisel and not the hammer) indicates clearly that other factors than the hammer itself are of more signal importance in its causation. The cramped position of the chisel hand with the more or less continuously maintained contraction of the muscles is one of these important factors. However, the hammer or the grip on the chisel, either alone or combined, are not sufficient to produce the condition, as is proved by the fact that it does not occur in the warmer seasons of the year when the stone-cutting industry is at its height.

The disorder of the hands is of a vascular character and not due to changes in the circulatory system, but dependent on vasomotor reaction. The physiological reactions are occasioned by three factors incident to stone cutting: (a) Mechanical irritation of the skin, (b) continued muscular contraction of a cramping nature and (c) cold. Of these three factors, cold is considered most important because (a) the condition occurs during the very cold weather and never in the summer, (b) warmth and measures to restore circulation (rubbing, swinging the arms and the like) cause its disappearance.

It cannot be caused by the effect of the air hammer alone because (a) it occurs in those who have not used the air hammer, (b) it does not occur in warm weather when the stone-cutting industry is at its height and, therefore, when the air hammer is most in use; (c) it occurs mostly in the left hand and not in the right hand in which the hammer is held.

The vasomotor disorder is of temporary duration and is not known to have resulted in permanent disability of the hand, nor itself to have been the cause of development of any other local or constitutional disease.

It is possible that once having occurred the person is rendered more susceptible to its reappearance, just as the one has had his ears or fingers frostbitten or "nipped" by the cold is more susceptible in these parts to the subsequent exposure to cold. This explains the occurrence of "white fingers" in stone cutters when not actually engaged at cutting but otherwise exposed to low temperatures.

The institution of measures to warm the chisel before and while using, enlarging the shank of the chisel and covering it to make it possible to hold without so cramping a grip, the wearing of gloves, and the discontinuance of the prevalent custom of blocking the exhaust outlet, and thus forcing a draft of chilled air out along the chisel and onto the fingers of the left hand would do much toward the prevention of this trouble.

*Abstract from an article entitled "The Effects of the Use of Pneumatic Tools on the Nervous System," read before the Mining Section of the National Safety Council at the Seventh Annual Congress held at St. Louis, Mo., September, 1918.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The labor leaders in the coal industry must be credited with a desire to maintain and support the instruments to which they have set their names in accordance, in each case, with the instruction of the delegates of the union. Repeatedly they have argued in favor of treaty keeping. Again and again they have pleaded that an agreement should not be broken just because the mine worker has had his cupidity aroused.

It has been the rank and file which has advocated breaking the pledged word. When the union saw that standing manfully by its agreements meant martyrdom it came to the operators and the Fuel Administration with many pious professions and advocated a rewriting of the contract, professedly in the interest of the operator and the nation, but really in the interest of the mine worker and the union.

UNION LEADERS PREFER THE HONEST COURSE

Full credit should be given to the union leaders for their preference for an honest course. Since the war began they have not themselves troubled the waters. They have only acted after others did the troubling. To excuse the tergiversations of the members of the union, they have hunted, of course, some condition in the industry that put a fair face on a faithless conduct, and they have presented this condition to the public somewhat shamefacedly, it is true, but often with much excellent effect. But it makes little difference who is the ultimate cause of agreement breaking—the mine workers or the union leaders—in any event the contract is broken and every one must fear that the signing of any more contracts with such people would be little better than useless. The solemn compacts seem to be made only to be broken.

On Sept. 8, 600 free-lance delegates of the northern anthracite field vowed that they would rather dig and fight than dig and starve and then added: "Resolved, That we, the miners of the anthracite region, unable to make a living for ourselves and our families, do hereby ask the right to be inducted into the army, where we shall be recognized as willing to do our bit for God and country."

DEMPSEY AND MACK LOOK TO THE FUEL BOARD

It may be noted that John Dempsey, district president of the United Mine Workers of America in the northern anthracite region, and John M. Mack, the treasurer, refused to recognize this convention, declaring it unauthorized and untimely. The union is discussing the matter with the Fuel Administration. Nine members of the Government are investigating conditions in the Wyoming Valley and in consequence Dempsey and Mack believe that the mine workers should be content to go along, for a time at least, with the contract they have, which has already once been modified. They feel that the mine workers should trust the Fuel Administration to grant a further modification if such a change may be proved in any way reasonable.

Of course, some remarkable statements were made at the meeting. One man said that in two weeks of mining he had earned only $24 and had been at an expense of $26 for powder and labor. It would be well to have these matters investigated authoritatively. The operator whose books have been submitted to every kind of scrutiny should be empowered to gather the facts regarding the work of his operatives so that he can meet these startling statements with a complete rebuttal. As it is, it is hard for any one to know just how diligently any man works. The time has not yet arrived when the time clock is installed at each mine and yet the war surely should demand that every man "work or fight" every moment of the eight hours in every working day.

The movement for more wages is not wholly socio-economical; it is partly political also. There will be an election soon and a general reapportionment in the union of the seats of the mighty. By attacking the contract, the leaders who approved it, who commended it to the mine workers and who later defended it are themselves attacked in a most vulnerable manner. The unshipping of the union leaders is the end aimed for.

HOW MUCH OF THE TROUBLE IS POLITICAL?

But it must not be denied that much of the agitation has a more direct ground and that nearly all the followers of the agitators are actuated by socio-economical and not political motives. It would be absurd to say that the mine workers do not want more pay. Everybody desires just that, no matter what the wage received and no matter whether or not there is a union leader to be discredited.

The mine workers are still restive under criticism. They feel that all the good words said about the shipbuilders are a reflection on other workers, notably on the miners. They also feel resentful because the remarks on liquor drinking are made too generally inclusive. When the men from Raub, Haddock, Pyne, Kingston and Pettebone Shafts, of the Wyoming valley field, recently met they declared that mine workers were the factors in the closing of saloons at hours when liquor tempts the toiler on his way to his work. But this does not answer the statement that some are slacking to drink liquor. It only shows that there are good mine workers and bad, and it exhibits how powerful the better element is if it will do its utmost to promote temperance. These same mine workers declared that they had organized patriotic parades on pay nights, rounded up men from the saloons and had done all in their power to keep a desire for recreation, bibulous and other, from interfering with fullday progress, six days per week.

ANGER OF MINERS SHOWS THE RIGHT SPIRIT

On the whole, no man can blame the mine workers for being sensitive. *Coal Age* recently spoke plainly about the miserable coal loaded out at some certain coal mines throughout the country; and accordingly the honest folk who never sent out dirty coal and lived in a part of the country where a little competition still made careful preparation necessary wrote in and said: "The miner was wholly to blame. Operators never put out dirty coal," and so forth. An honest man does not like to hear evil of his less honest fellows. He feels besmirched with the rest. For this reason we fear it will serve few useful ends to tell the straight-laced temperate miner that all the admonishment against drunkenness was addressed to the man whom he rounded up from the saloon, whom he invited to a patriotic rally and whom he had prevented from securing a drink in the barroom before working hours of the morning.

After all is said everyone must be glad that the mine worker is so wrathful. The number angered is a good indication of the number who feel the needs of the time and lament the intemperance existing. If when the public raved the mine workers snapped their fingers we might fear for the outcome. But, as has been shown, they denounced the aspersions and the louder their denunciations the more sure we are that they purpose to make them untrue.

If the men from Raub, Haddock, Pyne, Kingston and Pettebone will kindly permit it we will mention a difficulty in Winber, Somerset County, Pennsylvania. This mining town, owned by the Berwind-White Coal Mining Co., has

a large foreign population which besports itself with christenings and holidays and even with funerals. It is hard for an American to realize the joy that some foreigners find in the obsequies of a fellow countryman. As a result of these three sources of jollification, celebrated, however, in but one way—by copious liquor swilling—it has been extremely hard to get a full week's work from many of the men.

But again foreigners are not all alike. Some are quite ready to make the sacrifice required. At Mount Carmel—to return to the anthracite region—the Russian Brotherhood has agreed to postpone its convention of Sept. 16 so as not to interfere with the operation of the mines. Michael N. Halkowicz, supreme secretary, received a letter from James B. Neale saying that the action of the brotherhood "is most gratifying to the Government."

On Labor Day 600 employees of the Temple and Raub coal companies, in the Wilkes-Barre section, worked as if it were a regular weekday. The Haddock mine also worked 50 per cent. strong. Cast your eye on the preceding page and note that the Raub and Haddock men were among those who protested against the aspersions on the coal miner. If they all worked like Raub and Haddock men the unkindly criticisms regarding slacking and drunkenness would probably never have been written. The operators in the Lackawanna district had planned for a full day's production, but none of the collieries operated. Nor was it any better in the Lehigh field, near Hazleton. An outing was celebrated and the mines were deserted. However, three of the washeries of the Hudson Coal Co. near Wilkes-Barre were operated, as usual.

Fairmonters Rest Sept. 2 but Work Overtime

On Sunday, Sept. 1, the West Side mining section, near Wilkes-Barre, held a parade in honor of the full day's production that they were proposing to produce on Labor Day. We have already noted how Monongah mine in the Fairmont field worked overtime on Aug. 30 and 31 so that the tonnage of that plant would not be reduced by the Labor Day holiday. The action at Monongah seems to have been that followed by all or at least nearly all the plants in the Fairmont field and vicinity. Dr. Garfield's request was not that Labor Day be not observed, but that, as in the week including July 4, the tonnage of the week should be maintained at its normal level.

In the Kanawha region of West Virginia, the operators of the Kanawha Coal Shippers' Association, 32 being present, met in Charleston, Aug. 30, to discuss bonuses for labor, the securing of clean coal, production and distribution. The bonus trouble is still worrying the operators, for if it is paid the mine workers press for its incorporation in the scale and if it is dispensed with the mine workers are up in arms at the reduction in pay.

The operators in the Fairmont field of northern West Virginia as a body have voted against a recognition of the union. A scale committee had been appointed by the operating committee of the northern West Virginia Coal Operators' Association to meet with the scale committee from the mine workers, who just recently have been unionized. The two committees agreed on the Flemington scale, which is in force in the vicinity of Grafton and at points adjoining the Fairmont field. When this agreement was presented to the directors of the operators' association they voted not to recognize the union at all. The operators, however, which desire to recognize the union, decided to do so individually, and as the Consolidation Coal Co., the largest operating interest in the field, favors this course it seems hopeless for the smaller interests to hold aloof.

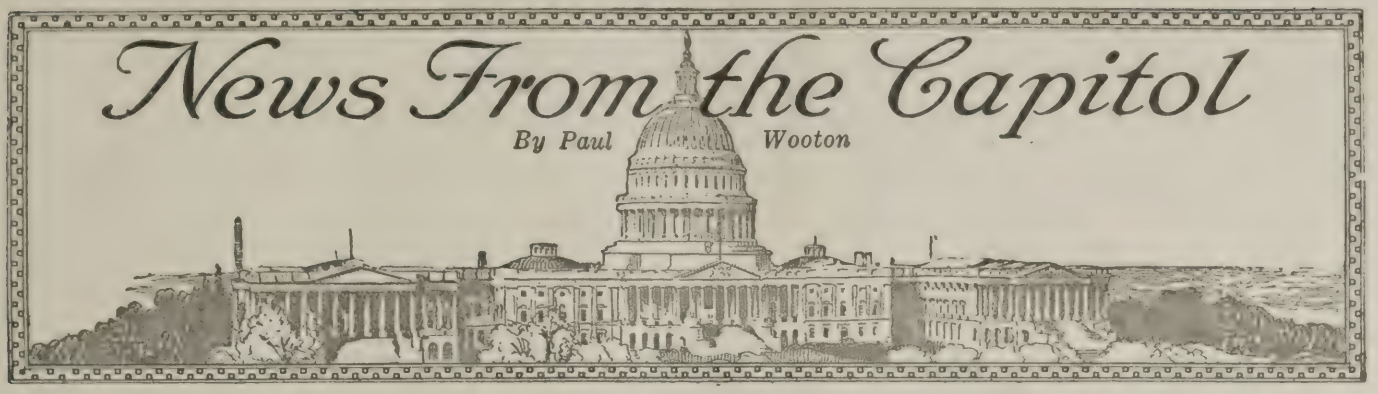
The strike at the Brule mine in the Edmonton district, Alberta, has been settled, and 500 men who had been on strike several days about the condition of the washhouse have gone back to work.

A strong movement against double shifting at the mines has arisen in Fernie and Michel, B. C., and the attack on it has been based on its unsafe features in the mines of that section. The Crow's Nest Pass Coal Co. seems to doubt whether the agitation is really based on safety. It believes that the agitation has its origin in the inconvenience of the double shift. As a result the company proposes the placing of three men instead of two in each room, thereby maintaining the tonnage despite the introduction of the single shift.

But the men regard this as an assurance of lower earnings, and it will be argued that if it does not lower their earnings it will be because three men mine more coal than two, and, inasmuch as they mine more coal, will the firedamp be evolved in greater quantity and reach a more dangerous percentage. The larger quantity of gas, it will be said, will be evolved in one single shift and must be removed as generated. More men to injure, more gas to work the injury may seem to some the conditions thus proposed. The company is reducing the gas percentage by provisions taken and whatever action is decided on it is to be hoped that it will be such as will spare the mines from further disastrous accident.

Missouri Miners Promise Future Strike

The Executive Board of District No. 25 of the United Mine Workers, which has jurisdiction in the union affairs of Missouri, has a grievance against the Southwestern Interstate Coal Operators' Association. It appears that the employees of the Kansas City Midland Coal and Mining Co. and of the Western Coal and Mining Co. presented a grievance against those companies to the association, but W. L. A. Johnson, William Richardson and J. J. Ward, representing the association, sustained the coal companies against which the union made protest.



The Executive Board of the Missouri branch of the union says in a letter to F. W. Lukins, president of the association, that the decision of Johnson, Richardson and Ward was in conflict "with the letter and spirit of our joint agreement," and says "We wish to inform you that while under our contract, we have the right to call a strike, we decline to do so because the Government has urgently requested that nothing be done to disturb the production of coal."

The communication further declares that the union postpones the calling of a strike because of the loyalty of its members to the national interest, but "we want you to distinctly understand that we are not waiving our right to call that strike and that we are not waiving the principle in the contract that the operators have thus far refused to recognize. We wish further to inform you that, should your association and the above-named companies continue to do business with the United Mine Workers, some day in the future the contract which the above-named companies and the representatives of your association have ignored will be recognized."

Asiatic Labor for Canadian Coal Mines

In official, political and labor circles throughout British Columbia the recent declaration of Frank Carvell, Canadian Minister of Public Works, that Asiatic labor must be imported for Canadian coal mines if the fuel required for the absolute necessities of Canada cannot otherwise be produced, has occasioned much comment. The suggestion that orientals should be given access to Western Canada without restriction meets with general opposition, and any step having in view their employment in mines in larger numbers than at present would meet with vigorous action, not only from the mine workers' unions, but from every branch of organized labor. The press also opposes the idea, with the single qualification that it might be forced on an unwilling public by the exigencies of a coal famine. To quote one of the leading journals of British Columbia:

"The minister of public works may not understand all the objections to the policy he proposes. His conditional plan would find the strongest opposition in this province, which, of all others, is best acquainted with oriental problems. Nevertheless the statement of Mr. Carvell will have strong support among the people if they find a coal famine upon them. Fuel must be provided, and in the last emergency the Government would undoubtedly call on Asia or any other country for help. But the last emergency has not yet arrived and it should not be too late to avert it."

Reduction in Price of Byproduct Coke

A flat reduction of 30c. a ton in the byproduct coke price has been made by the Fuel Administration. An exception is made for byproduct coke produced in Alabama and in Washington. The principal reasons for the reduction are that the high-priced contracts for coal have expired and that a regular supply of coal now is obtainable at ovens. The price of coal also has been reduced 10c. since the previous coke prices were made.

Indiana and Illinois Coal for Michigan

Action on the part of the Fuel Administration last week makes it necessary for the lower peninsula of Michigan to become a heavy purchaser of Indiana and Illinois coal. All other coals have been zoned out of that territory. This action was taken only after it became evident that Indiana and Illinois coals would not be used voluntarily to any extent in the lower peninsula. There are considerable stocks of high-grade coal in the lower peninsula, which it is expected will be stored for use in the dead of winter. This is one of the steps being taken by the Fuel Administration to limit the use of high-grade coals to essential uses.

Investigating Electric Power Situation

Increased attention is being given to central power plants by the Fuel Administration. An effort will be made to improve the service being given by these companies. An inquiry is being directed by the Fuel Administration to operators securing electric power from central plants asking for certain information with regard to the power situation.

Federal Trade Commission Arraigned for Handling Coal Matters

On the Federal Trade Commission's handling of matters pertaining to the coal-mining industry was based the strongest of the indictments against the Commission by the Chamber of Commerce of the United States. The arraignment of the Federal Trade Commission came in the form of a report from the Federal Trade Committee of the Chamber of Commerce, of which Rush C. Butler is the chairman. The reference to coal in the report is as follows:

Before the Fuel Administration was established, the Commission undertook to influence distribution of anthracite coal, with the acquiescence of the operators. Even if the Commission's belief that there were beneficial results is accepted, it remains true that this was not a proper function for the Commission to exercise and that it did not have facilities essential for the task. It is common knowledge that distribution was so imperfect that proper supplies were not accumulated for the following winter and that widespread hardship ensued.

The Commission later perceived a similar function for itself to controlling the distribution of bituminous coal. It undertook to advise Congress that all bituminous coal should be sold through a common agency at one price for each quality and that the operators should receive individually their cost with an added profit. The Commission itself was to be the agency. This recommendation it made in a report which showed scant data regarding bituminous coal. Legislation under which the Fuel Administration was created authorized the President to utilize the Commission as a distribution agency, but this authority was not exercised and by proclamation of July 3, 1918, most of the remaining activities of the Commission with regard to coal were transferred from the Commission to the Fuel Administration.

In August, 1917, the Commission gave advice to the President which resulted in the prices fixed by him on Aug. 21. The Commission's prices were constructed upon a new computation of costs, which excluded, among other things, interest and depletion. The Commission stigmatized reserves as coal held out of use and allowed no interest for investment in reserves. Part of the data before the Commission was an anonymous estimate of costs in important fields. The correctness of the Commission's method of computing costs is not here in question. The objections on the score of public interest are that the method was new; that it was applied at a critical moment when customary and honest bases of costs should not have been questioned; that it was arbitrary in that it had not been subjected to scrutiny at such hearings of the persons affected and the public as any responsible public body should accord; and that it placed below the cost of production the prices of at least 40,000,000 tons of bituminous coal in the annual supply. In other words, the Commission was not prepared to undertake the highly important rôle it essayed, and dealt recklessly alike with national interests and personal rights.

Fuel Administration to Settle Power Controversy

Settlement of the controversy with regard to the charge to be made for power in Harlan and Bell Counties, in Kentucky, and the contiguous region in southwestern Virginia, has been put in the hands of the Fuel Administration. The action to this end taken by the operators is expressed by the following resolution:

"Resolved, that the committees from Harlan County, Kentucky, Bell County, Kentucky, and southwestern Virginia, representing the coal companies which are consumers of power from the above mentioned fields,

agree to submit the question of fixing the amount of increase necessary to provide the power companies the funds to serve the above consumers with satisfactory power to the Price Fixing and Engineers' Committees of the United States Fuel Administration, and we hereby agree to abide by the recommendations of the said committees, and will so recommend to the respective coal operators of our fields."

Storage Limitation Has No Effect on Prices

Establishment of a system of storage limitation was expected by some to result in breaking the coal price. The storage regulations, however, have gone into effect and no evidence has reached Washington of the price having fallen below the maximum fixed by the Fuel Administration.

Many Miners Worked on Labor Day

A large number of cases in which mine workers sacrificed their Labor Day holiday in order that coal production might be continued have been reported to James B. Neale, the director of production for the Fuel Administration. In some cases the miners worked throughout the day. In others they worked most of the night preceding, so as to be able to take part in the exercises of the holiday. In the Pocahontas and Tug river fields, 1219 cars were loaded on Labor Day. The normal day's loading is only 5 per cent. greater. The coal mines in the Connellsville district of Pennsylvania produced 75 per cent. of the normal output.

Government's Attitude Toward Nonwar Work

One of the clearest statements of the Government's policy toward unnecessary activities or work which can be deferred is contained in an announcement under date of Sept. 6, by Judge Edwin B. Parker, the priorities commissioner of the War Industries Board. Judge Parker, among other things, says:

While it is not the policy of the Government to unnecessarily interfere with any legitimate business, industry or construction project, it must be borne in mind that there is an imperative and constantly increasing demand for labor, material and capital for the production and distribution of direct and indirect war needs, to satisfy which much nonwar construction must be deferred. A full realization of this fact by all loyal and patriotic citizens, including state and municipal authorities, is all that is required to postpone such construction activities as interfere with the war program. The state and local representatives of the Council of National Defense are with confidence depended upon to fully acquaint the whole people of these United States with the pressing need for the most rigid economy, measured not only in terms of dollars but in terms of labor, materials and transportation service. The construction projects which must be now deferred may be undertaken when we shall have won the war and will then furnish employment to the returning artisan now on the battlefront as well as those who will then be released by strictly war industries.

Works which require new permits or licenses, are as follows:

1. After having first been cleared and approved by the War Industries Board, those undertaken directly by or under contract with the War Department or the Navy Department of the United States or the United States Shipping Board Emergency Fleet Corporation, the Bureau of Industrial Housing and Transportation of the United States Department of Labor, or the United States Housing Corporation.

2. Repairs of or extensions to existing buildings involving in the aggregate a cost not exceeding $2500.

3. Roadways, buildings and other structures undertaken by or under contract with the United States Railroad Administration or a railroad operated by such administration.

4. Those directly connected with mines producing coal, metals and ferro-alloy minerals.

5. Public highway improvements and street pavements when expressly approved in writing by the United States Highways Council.

To Save Coal in Power Plants

Consolidation of electric power plants is going ahead rapidly, due to the activity of the Fuel Administration along with the coöperation of other Government agencies. Since a kilowatt of electricity has the same power regardless of the amount of coal used to generate it, a great saving of fuel is effected when plants requiring five, six or eight pounds of coal to generate a kilowatt are eliminated and the electricity furnished from a plant which requires but two pounds of coal to make the same amount of electricity.

Furloughs from Military Service

Furloughs from military service will be used to a greatly increased extent now that the new man-power act is in operation. William M. Ritter, who is thoroughly familiar with the requirements of the coal-mining industry, as well as those of other activities, has been named the representative of the War Industries Board to look after industrial furloughs. He will be the point of contact between the War Industries Board and the office of the Adjutant General.

The Fourth Loan Is a Victory Loan

We Must All Grow Old Some Time, But—

We don't want to be crippled also. The old age of a man who has been unfitted for industry is full of sorrow and often of bitterness toward even his own family. As far as he possibly can every man should keep a whole skin so as to be useful to his fellowman in the war or in industry. Neither the army nor industry can use a cripple. Avoid, therefore, all the accidents you can.

EDITORIALS

ON PAGES 52 and 53 of the advertising section of this issue of *Coal Age* will be found an advertisement to which the attention of every reader is directed. It gives in detail a plan of preparing the way for the sale of the Fourth Liberty Loan. That announcement must command not only careful and immediate attention, but action also.

It is a poor mouth that just now pleads self-interest. The nation's need is not to be urged on any such narrow basis. Yet it is not difficult to see how the energetic carrying out of this plan will not only help to sell the Liberty Loan, but give an impetus to business—your business and that of your employees.

* * *

Business depends as much on enthusiasm as on anything else. Given a win-the-war spirit, the coal output will develop to full proportions. The miner will try to overcome the difficulties of coal transportation by a readiness to fill railroad cars whenever they are available and a willingness to wait for them whenever they are promised. He will put up with other drawbacks also—at least so long as he realizes that the operator cannot be blamed for them.

The win-the-war spirit will transform the mine worker into a catch-as-catch-can worker striving ardently for every opportunity to "boost the game." It is the "win-the-pennant" spirit that makes baseball players ready to act on the instant and ready to wait for the opportunity which only rarely comes to them.

When all the batters are pounding the ball to the outfield and the bases are empty, you won't find a baseman getting ready to go home, or slouching over to the players' bench. Note him! He is awaiting the unexpected with as much energy as if he knew it was coming. This is how it is on the baseball diamond. But put the same man in the mine and a similar condition will often send him home.

The electric locomotive on which he depends is, perhaps, gathering in another heading and will not reach his room for a while, so, discontented, he takes his pail and his coat, runs like a streak for the parting and goes home. He hasn't the win-the-war spirit. He is not in the war. The mine workers are not all of that kidney, but what of that? There are some who are, and they must be brought to the right point of view so that they may do their part and put further enthusiasm in all those who are already doing well. A meeting such as is advocated will serve to put ginger into the whole organization from superintendent down to trapper boy.

* * *

THE tremendous impetus which Charles M. Schwab has given to shipbuilding has been largely achieved by making every individual engaged in the industry feel a personal responsibility for results and a personal pride in helping to make great results possible.

This spirit of accomplishment in the shipbuilding industry has been brought about by the leaders—the employers—the bosses; whatever you choose to call them; making it a business to come in personal contact with the workers and to inspire and enthuse the men with a sense of the importance of their work for victory in the war—a sense of personal responsibility, and a spirit of teamwork.

* * *

The creation of that spirit among the workers of the nation in all lines of activity would be of incalculable benefit to the workers themselves, to employers, and to the nation.

Concretely two of these results would be: To quicken and increase the response to all war measures such as Liberty Loans—War Saving Stamps—the draft—food and fuel saving and to make the worker feel more keenly his responsibility to do a full day's work (no matter what its character) to the very best of his ability. It would make him feel the necessity of sticking closely to his job.

Employers generally should pursue with intelligent enthusiasm the plan of Win-the-War meetings proposed as a means to aid in the rapid flotation of the Fourth Liberty Loan. The results of such action will not only be helpful in the loan drive, they will be permanently helpful to the nation through the development of a keener realization by the worker of the importance and dignity of his individual job and the necessity for personal responsibility and helpful teamwork.

* * *

EVERY employer can be a leader and a center of influence in this work. The man who operates a small mine with relatively few employees may feel that his circle of influence is too small to be worthy of any effort. That is a mistake. It is the aggregate that counts, as the announcement of the plan very clearly points out.

The man who is in a relatively small circle may not hold so pretentious a meeting—it may not be formal or run under parliamentary rules—it may not be especially announced, or accompanied by music and oratory. But the man who will quietly call his employees around him and informally, thoughtfully, lead discussion into win-the-war channels, pointing out the importance to the individual of doing his best in support of Liberty Loans and all other war activities, can do a real service in this way. It can be so well done in no other way. And ten thousand such little meetings would produce an enormous aggregate result.

* * *

Some operators may feel a degree of reticence about calling a meeting at which it would be necessary to speak or, at least, preside. That feeling it is, of course, necessary to combat. An operator, manager or superintendent should be a leader of men. He should be able to address them, not only about the war, but about a hundred and one matters relating to industry and peace.

But if any mine official fears his inability to perform this duty and feels it embarrassing to talk to his

men, let him join with officials of other mines nearby and call a larger meeting. He can then avail himself of the oratorical ability, magnetism and leadership of others.

Whether his opportunity be great or small, every American mine official should carry out the idea presented in a definite systematic manner. The "program" booklet which is mentioned in the announcement will be found most helpfully suggestive in furnishing plans to meet all circumstances.

Safety Relies on "Come-Along" Spirit

SAFETY movements fortunately fell early into the hands of men who preferred "Come Along" to "Go Along," and their propaganda has, for this reason, been strikingly free from the word "Don't." In the measure in which they have sought to lead and not to drive has been their success. In most cases, without the help of the law, without the support of the power of discharge, without the entire good will of all elements in the management, without even the whole-hearted support of the men whose lives and limbs were to be saved, they have been forced to use the compelling powers of good will, sympathy and understanding. They have been obliged to praise what good they found and to be a little blind to the bad they encountered, and so they have been compelled to work only gradually and by moral suasion toward the best.

Their restrictions have done them no harm. The very weakness and halting character of their work have promoted a feeling of respect. For safety has, at no time, been rendered obnoxious by compulsion. It has been made a pleasant and alluring creed. No fierce penalties surround it. Jail sentences are not relied on to give it assistance, nor does it gain much strength from suspensions or discharges. The safety man does not fulminate. He coaxes, and the results follow. We would all always rather be led than driven. We would even prefer to have a suggestion from a safety man than an order from the executive head of our department. Safety does best when it is treated as a matter of sentiment. Hard-headed men will always regard it as a little mawkish, but thank Heaven, the hard-headed do not predominate; the men with sentiment and moral imagination always outnumber and outvote the others. The ideal wins. Was there ever a better industrial ideal than "Safety First"?

All Derailments Are Potential Casualties

AROUND the mines you hear mine workers talk glibly and with indifference about the derailment of a car or or the wrecking of a trip, though in nearly all derailments and wrecks abides the potentiality of accident to life and limb—of a casualty, at least, if not of a fatality. Until we get to the point of trying to avoid bloodless accidents as well as the other kind, until we begin to investigate them as seriously as others, we shall never reach the ultimate in safety.

But even in our investigations of a fatal mine accident we sometimes satisfy ourselves with the knowledge that it was caused by a derailment. It finds final record in just that way. It is not marked down as the result of tight gage, wide gage, lack of elevation, bad curve, low joint, no fishplate, lack of spikes, absence of rail brace, lack of guard rail, rotten ties, fallen roof rock, coal on road, room frog, light rail, excess speed, failure of brakes, steep grade, locked bumpers, broken drawbar, failed coupling, damaged bumper, bent axle, poorly built car, overload, pushing instead of pulling cars, starting trip, a too-rapid stop, a sudden change in grade which takes up slack, an ill-thrown switch, a high plank, props piled too close to the road, or a car pushed too near the traveling track.

There are many causes, and we should know just what they are. Diagnosis is two-thirds cure, but as yet we have little or no diagnosis. As the definition of a primary cause derailment is too wide of the mark. It serves as much, perhaps, as when we say in recording an accident, "Wife and six children left without support." It is the record of a result and not the record of a cause. It informs us that something is wrong, but not just what.

The reason is because we do not wish to face the real cause. Derailment is so delightfully vague. It does not uncover the real nature of the neglect. The question of safety will never progress unless it is approached in the proper statistical spirit. If we can say the low joints cost so many lives and so many hours of lost labor in 1918, and add that they even cost so much money, we shall have something to guide us as to the value of efficient track supervision. In fact we should also keep a record of the place where the accident occurred. We want no Deadman's Curves or Deadman's Hills in our mine, or even Casualty Curves and Casualty Hills. Let us mark all the danger points in our workings plainly. Perhaps they need a change of curve, or of grade, or of operating method, or it may be a guard rail, a road brace or some track elevation. .

What makes for safety makes for industrial surety. What kills a man, destroys a car or lames a mule. What throws a car off the track, spills coal along the roadway. What derails a locomotive, causes timbers to be torn down. What makes a wreck, makes also an idle tipple and sends men home before the day is done. Safety should be the first consideration. If you write it, however, as "Surety in operation is the first consideration," you make it less forceful and less true. Nevertheless, in doing so you put a new light on the matter.

Reckless road maintenance and carelessness in the repair of equipment never did and never will pay, apart from the accidents to persons resulting. In that last accident you had, how many men were laid idle, how long were you repairing cars, and how much material was needed? Even if no one was hurt you probably lost more than would have paid for the hire of a tracklayer for a month or more. When you are short of men, the repairmen are the first laid off. You then begin to lose more by accidents than you can ever hope to gain by all manner of such ill-placed economies.

In many mines may be found places where cars are handled with undue roughness, yet without casualties resulting at those particular points. Such places are the kickback gathering "pits" on tipples, the long gravity planes on hillsides and starting places for long electric locomotive trips. If we would have safety, conditions at these points must be modified so as to make operation less destructive to equipment. A little consideration of the trials of our mine cars may advantage us much in our quest for safety from derailments.

DISCUSSION BY READERS

Permissible Explosives in Mining

Letter No. 1—I read with interest what W. H. Noone had to say regarding permissible explosives, when discussing safety in shotfiring in mines, *Coal Age*, Aug. 1, p. 234. Having had charge of a large number of men and the oversight of shotfiring, in the last few years, I am convinced that the introduction of permissible explosives in coal mining has been the means of saving many lives.

It is a well-known fact that men who are the victims of accidents in blasting are very often those who have had a long experience in handling black blasting powder. Their experience, however, has not taught them to take the precautions that they know should be taken in blasting.

Experienced Miner Takes Chances in Blasting and Is Killed

A year or so ago, I made a special tour of a district in our mine for the purpose of discussing with each man the methods he employed in preparing and firing a shot. The last man I approached with some hesitation, because he was an old miner who had had 30 years' experience in cutting and blasting coal. I felt it would be an insult to ask him to show me how he prepared his squib, and to explain what precautions he took for his own safety and that of others. I dealt with this man very much as a cat would play with a mouse and, without injuring his feelings, got him to show me how he prepared a squib, and his answers to my several questions convinced me that he understood his business thoroughly.

The following morning, I missed several men from their places, and, fearing something was wrong, hurried along until I reached the man's place of whom I have just made mention. To my surprise and sorrow, I found him lying unconscious on the floor of his place, with several lacerations and a fractured skull, from which he died a few minutes later. Following my talk with him the night before, nothing could have convinced me that he would ever take the desperate chance that his laborer and others had seen him take on many occasions and which had, at last, cost him his life.

Shortens the Match on His Squib

A similar instance of foolhardiness occurred when I entered a place where a miner had just finished tamping his shot and was withdrawing the needle from the hole. He sent his laborer to the gangway, and I watched him start to prepare his squib. As he placed it in the hole, I walked leisurely to the crosscut about 15 ft. back from the face, on the other side of the room. The miner followed me to the place, on the run, and had barely turned the corner of the crosscut when the charge went off, throwing a large quantity of fine coal into the opening, almost catching him, myself and another miner who was eating his lunch in the place.

Knowing well that he doctored his squib after I left him, I asked him for his squib box. Taking one of the squibs from the box, I prepared it in the same manner as he had done in my presence a short time before. Then, igniting the end of the match, I timed the action of the squib as 1 min. 8 sec. Taking another squib from the box, and preparing it in the same manner, I broke off a portion of the match, about what I assumed he had broken off when firing the hole. The time for the squib to get action, in this case, was 8 sec. only. The man, then, frankly admitted his mistake in shortening the match. This is but one of the many chances experienced miners take with black powder, which they could not take in the use of permissible powders.

Those who have used permissible explosives will bear me out in the statement that such a cartridge rarely, if ever, becomes stuck in the hole; there is no loose powder spilt from the cartridge when charging; and the charge can be tamped as effectively with a wooden tamping rod as with a steel bar. The charge hole is fired with an electric battery, after the miner has gone over his wires and made sure that there are no breaks. The firing is done from a safe distance and there is no chance of a premature blast.

Should the hole misfire, in electric blasting, the miner at once disconnects his battery and, after a reasonable time, goes over his wires to ascertain the cause. On the other hand, if a misfire occurs when using a squib or fuse, there is always the danger of the shot exploding several minutes later, which leaves the miner in doubt and uncertainty.

Permissibles in Inflammable Coal

When working in coal that was highly inflammable, I have used "Monobel," "Aetna" and other brands of permissible powders. In driving more than two miles of narrow work and working 15 chambers 800 ft. long, in this district, I have never had reported a fire, or a feeder being ignited by the use of these powders. The men have adapted themselves readily to its use and no complaints have been heard. My experience convinces me that mine fires and accidents of this nature would be reduced to a minimum by the use of permissible powders. On the other hand, I believe that as long as blasting is done with squibs, fuse and black powder, such accidents will continue.

We sometimes hear the objection offered that the higher cost of permissible powders stands in the way of their general use. However, it should be remembered that to offset this increased cost, there is a far greater reduction in the amount that may need to be expended as compensation for injuries received in the mine. The Bureau of Mines is to be congratulated on the success of the work they have undertaken in introducing permissible powders in coal mining.

Section Foreman, Woodward Mine.
Edwardsville, Penn.

Squibs vs. Electric Fuse

Letter No. 2—Referring to the inquiry of "Miner," *Coal Age*, July 20, p. 145, regarding the relative safety of squibs and electric fuse in blasting with black powder or permissible powder, and the request of the editor for a general discussion in regard to the safety and adaptation of single and double-tape fuse, squibs, electric fuse and electric detonators in blasting coal, permit me to offer the following from my own personal experience in this line of work.

In my opinion, while the squib is the simplest and cheapest means to employ to explode a charge, it is the most dangerous. The common squib consists of a thin paper tube ⅛ in. in diameter and 6 in. long, containing fine black powder. At one end is the match. Either the twisted paper is dipped in sulphur, which flames when ignited, or touch paper is used, which smolders but produces no flame. On that account the latter is generally considered safer than the sulphur match.

Dangers in the Use of Squibs in Blasting Coal

The chief danger in the use of the squib lies in the desire of miners to hasten its action by shortening the match, or by bending the sulphur match downward so that the flame will climb quicker to the powder. The match is sometimes moistened with oil for the same purpose.

Again, when the hole pitches, which is generally the case in inclined seams, a train of powder frequently follows the needle as it is drawn from the hole. The powder train may extend to the mouth of the hole and be fired by the flame of the lamp when igniting the match. In a gassy seam the gas may issue from the hole, and its ignition would at once fire the squib and cause an immediate explosion. In such seams it is quite common to strike a strong feeder of gas when drilling a hole preparatory to firing a shot.

Gas Ignited When Squib Is Lighted and Causes a Premature Explosion

An incident that happened some years ago when I was working as a laborer in the anthracite coal fields impressed forcibly on my mind the danger of using a squib when blasting in a gassy seam. In that instance the hole had been tamped and the needle drawn, and I stood behind the miner as he prepared the squib and placed it in the hole. In igniting the match with his lamp the gas coming from the hole was ignited and the flame issued some distance from the mouth of the hole, causing us both to jump instantly for the crosscut, which fortunately was only 6 ft. away. Hardly had we reached cover when the charge exploded, throwing the coal in all directions. Such an accident could only happen in the use of a squib.

Of tape fuses there are three forms—single-, double- and triple-tape fuse. The ordinary tape fuse consists of a train of fine powder laid in hemp or cotton, which is then covered with one or more layers of tape to render it waterproof. The rate of burning is from 1½ ft. to 2 ft. a minute and this is generally specified by the manufacturer. Depending on this stated rate of burning, the blaster estimates the length of fuse required to permit him to reach a place of safety before the shot will explode.

By cutting a greater length of fuse, it is possible to lengthen the time should it be necessary to do so, and in that respect the fuse has the advantage of a squib. However, the rate of burning cannot be guaranteed. It is common for a tape fuse to be injured and hangfire for a considerable time. When that happens the miner often becomes impatient and, believing the fuse has gone out, proceeds to investigate. This has been the cause of many a miner losing his life, being blown to pieces by the delayed explosion.

To reduce accidents from this cause the mining laws of British Columbia provide that, in case of a misfire, the place shall not be entered within 4 hr., unless an electric igniter is used, when this interval is reduced to 15 min., which is the time that a miner must wait after attempting to fire a charge that misses.

The use of fuse gives the thoughtless miner every opportunity to display his recklessness. Strange as it may seem, I have observed miners who, in order to save 3 or 4 ft. of fuse in firing a deep hole, would cut a piece of fuse 2 ft. long, attach it to the powder cartridge, then "spit" the fuse and, with a dummy cartridge of tamping material, push the charge to the bottom of the hole, follow this with one or two more dummies and run.

Another dangerous practice is to lace the fuse around a dynamite cartridge or even pass it through the same, which may start the explosive to burning and prevent its detonation by the cap. All such practices are impossible in electric ignition.

Electric Fuses and Detonators

An electric fuse, or "squib," as it is sometimes called, is a paper shell containing a mixture that flames when an electric current passes through it. The lead wires conducting the current pass into and are made fast to the shell. The cap thus arranged resembles an electric detonator. The ignition of the charge is caused, however, by flaming and not by detonation.

The electric detonator is a cap or shell of copper, containing a fulminate, which is detonated by the electric spark that passes between the terminals of the lead wires attached to the cap and causes the explosion of the charge. This has been fully explained, however, by the editor, on page 145.

In electric firing it is important to choose a detonator whose strength is adapted to the work required. Too strong a detonator is better than one not strong enough. No. 6 or stronger should be used with permissible powders. Tests show that an explosion is quicker and more complete and a smaller volume of poisonous gas is generated when a strong detonator is used; also, with a strong detonator less difficulty is experienced on account of the age of the explosive.

Precautions To Be Taken in Electric Firing

Before closing, I wish to state that electric firing by fuse or detonator is, today, the safest means to adopt, as it avoids all uncertainty and the dangers so common in the use of tape fuse or the miner's squib. In electric firing the simplest precautions insure safety. In the interest of the great safety-first movement, firing by other means should be prohibited by law.

In my experience, the following are the precautions essential to safety in electric firing: (a) Make sure

that the electric detonator is firmly secured in the explosive. (b) Avoid the use of gritty tamping material that might injure the lead wires and short-circuit the current. (c) Make sure there are no kinks in the lead wires and avoid injuring these wires in tamping. (d) Clean the ends of the cable wires and the lead wires before joining them. (e) Insure a good contact of these wires by twisting them firmly together. (f) When connecting the cable wires with the terminals of the battery, insure a good contact by cleaning the wires and screwing them down firmly. (g) Examine the battery occasionally to see that it is in good condition and that the parts are not corroded, demagnetized, or the gearing damaged. (h) Never connect the cable wires with the battery, until the moment of firing and after making certain that no one is in the vicinity of the blast. (i) The shotfirer must have full possession of the key to the battery. In using the battery, the handle must be plunged or turned with a quick firm action.

J. W. POWELL.

Cassidy, B. C., Canada.

Letter No. 3—The question of firing shots with the old miner's squib or tape fuse, as compared with electric firing, takes me back, in memory, to the days when black powder was fired by squibs and fuse and many accidents were the result. Today, the use of permissible powders fired by electricity has greatly reduced the number of these accidents.

Briefly stated, the chief advantages in electric firing are that the charge can be exploded at the exact time desired. No time is wasted in waiting for the fuse to burn and the miner cannot take chances in firing, as he does in the old way. Formerly, it would occasionally happen that the squib was imperfect and the powder extended into the match, so that the shot would go off when the match was lighted before the miner had an opportunity to get away.

At other times (but this would happen more often in the use of fuse than when the shot was fired with a squib) the shot would hangfire, and the miner would come back thinking it was a misfire. At times, he would even start to drill a second hole to blow out the charge and would be caught by the explosion of the first charge.

When using fuse, the miner would often crimp the cap on the end of the fuse with his teeth instead of using a pair of pincers for that purpose. In some instances the miner's head would be blown off or he would lose a hand by the explosion of the cap when crimping it to the fuse. It is my belief that there is no safety for the miner in the use of either squibs or fuse.

REQUIREMENTS OF BATTERY IN ELECTRIC FIRING

A safe battery, for electric firing, must possess certain requirements. The parts of the battery must be inclosed in a tight substantial case so that no contacts will be exposed, except the binding posts or terminals to which the firing leads are connected when the battery is to be used. In order to provide against the unauthorized use of the battery, it is provided with a detachable handle or a key, without which no current can be generated.

The battery must be in charge of an authorized and competent shotfirer, who must never connect the firing leads with the terminals of the battery until all steps preparatory to the firing of the charge are completed. He must permit no one to make these connections but himself, and then only after he has made sure that everyone is in a safe place. Immediately after firing a shot he must disconnect the firing leads and remove the handle or the key from the battery.

Should the shot fail to go off the shotfirer must permit no one to approach the place for at least 5 min. after making the attempt to fire the charge and after the lead wires have been disconnected with the battery. To insure the proper working of the battery, it should be inspected from time to time and tested to insure that its capacity for firing a charge has not decreased.

Leckrone, Penn. SHOTFIRER.

Sealing Off Fire on Intake

Letter No. 13—I have been much interested in the discussion, in *Coal Age*, regarding the sealing off of a mine fire that has gained considerable headway, in an intake entry. Having had several years' experience fighting mine fires, in the Newcastle district of Colorado, I desire to add a few remarks giving my own ideas in reference to this subject.

In the first place, I believe in being prepared when operating a fiery and gaseous district in a mine. To this end, let me suggest that a wise precaution to take, in such a case, would be to build two frames of 6 x 8 in. timber, one in the intake and the other in the return airway of the section.

These frames should be walled into the rib to the depth of a foot, using concrete or brick for the purpose. To provide drainage, a short piece of pipe with a valve should be built in where the ditch passes under the wall. On the roadway, at this point, two short lengths of rail should be used, which can be quickly taken up and the floor prepared when there is need of closing the stopping.

Should the occasion arise requiring the stoppings to be closed, the work must be started on the intake by boarding up the opening in the frame. Starting at the top, the boards should be made to lap each other about a half-inch, which makes a better job when sealing the cracks with clay or plaster. This will allow of a space of 5 in. for concrete or brick.

The return stopping is now started about a third of the way down from the top and the boards made to lap about a half-inch and plastered, in the same manner as in the intake. A pipe or valve should be inserted in the stopping and left open until the stopping has set.

While building these stoppings, the air current should be short-circuited by making an opening in the next stopping outby. When the work has been completed thus far, further operations should be suspended for a period of 24 hr., after which both stoppings should be finished with brick or concrete.

In my opinion, it is a grave mistake to close the return stopping first. This would have the effect of shutting in a quantity of air behind the stopping, with the result that an explosive mixture would form and an explosion take place, which has proved to be the case, more than once, in the Newcastle district.

Reliance, Wyo. WILLIAM HARRIS.

Priming a Cartridge

Letter No. 2—Referring to the letter on this subject by "J. P. G.," *Coal Age*, Aug. 15, p. 327, permit me to say, that in the interests of safety and to secure the best results in blasting a detonating cap should never be inserted in the side of the cartridge or the lead wires laced around the same, as he has described.

My experience convinces me that there is only one safe method of inserting a cap in the primer. For this purpose, the end of the primer cartridge should be opened and the cap inserted until it is fully covered by the contents. The paper at the neck of the cartridge should then be securely tied about the lead wires with a string so that the cap cannot be withdrawn when charging the hole. An experienced shotfirer will provide himself with string for that purpose so that no time will be lost when preparing to shoot.

Taking a half-hitch with the lead wires about the cartridge is liable to cause a bad kink or injure the covering of the wires and cause a misfire. Also, when the detonating cap is inserted diagonally in the side of the primer it is apt to be drawn out of the cartridge, or even exploded, by rubbing against the sides of the hole when the primer is being pushed home.

Let me suggest, here, that where two or more cartridges make up the charge it is well to open the paper where the cartridges come in contact with each other, and insert the end of one cartridge into the open end of the cartridge below it, so as to form a better contact of the contents and make a more solid charge.

Perryopolis, Penn. R. W. LIGHTBURN.

Americanizing the Foreigner

Letter No. 3—After reading the interesting letter of "Experience," *Coal Age*, Aug. 8, p. 286, which deals with a subject in which I have taken much interest in recent years, I could not refrain from expressing my views, which I hope will be found worthy of publication.

It is hardly necessary to say that the coal-mining element, today, taken as a whole, is inferior both mentally and socially to the old-time Scottish, English, Danish and other nationalities that comprised the mining classes a few years ago. Then the miner took pride in keeping his place in A-1 shape and producing a good tonnage. In those days there was no little rivalry among mine workers, each of whom would strive to gain the notoriety of being the best miner in the camp.

Times have changed, however, and "shooters and loaders" are the substitutes of the old-time miners. This reference is not offered as a criticism of the present-day miner, but is intended merely as a comparison of the conditions brought about by the change in mining methods. The application of scientific principles to coal mining has so revolutionized the coal-mining industry that but a few days' experience is required to enable a man to load a tonnage far in excess of the average daily production in former days. A coal miner today is merely a shoveler of coal, which is cut by machine and drilled by a power auger attached to the cutting machine, after which the coal is blasted down by shotfirers.

These conditions have made it possible for the foreigner, with practically no education and often with little mining experience, to earn good wages in our mines. As a result the bulk of the mining element in this country, today, is comprised of this class, and it can be said truly that we would be handicapped by a shortage of labor, even in normal times, were it not for the foreign classes employed in our mines.

I cannot agree with "Experience," when he states that the work of the executives of coal companies and operating officials has "seemingly failed in its purpose." On the contrary, I think that much lasting good has been done through their efforts. It is my belief that coal executives and officials are not competent judges of the results of their own efforts.

Let me ask such as feel discouraged in this line of work, whether they are not attempting to undo, in a few years, what has been many years in the making. The foreigner is not in his present plight through choice, but is the victim of circumstances and environment. Our desire to Americanize him, by changing his mode of living to which he was born and bred, must be tempered with almost infinite patience and perseverance. Progress will be slow and we must not be discouraged.

WELFARE WORK A NECESSITY AT ALL MINES

To insure the greatest measure of success, efforts to improve the foreigner must not be confined to the larger companies. It is necessary that like efforts be put forth by those in charge of smaller operations. During the past few years, I have frequently noticed the difference in the customs of those foreigners who have been employed at plants where social welfare was in progress, and those where no such efforts were put forth. I have observed that foreigners coming from places where the company was interested in their welfare not only inquired as to the conditions in the mine, but they were particular to find out about the living conditions, and to inquire what schools were available for the children, etc. On the other hand, the foreigner who had not experienced these advantages was only interested in knowing whether a good working place would be given him. Apparently, it mattered little to him what his family might have to endure.

A good illustration of the improvement already made in the mode of living of the average foreigner, today, is that seldom more than two men are observed to occupy the same sleeping apartment, while, formerly, it was a common thing to see from 10 to 15 men accommodated in a three or five-room house. The problem of improving the foreigner would be greatly simplified if it were possible to retain the same employees at one camp. The mine practicing the social uplift of their employees would, then, soon have a higher class of labor than operations where no such work was attempted.

The fact that there are some families among the foreigners whose customs it is difficult to change and whom it is hard to influence is no reason for condemning the foreign classes, since there are just such families born and bred on American soil. We must strive to surround such with improved conditions, in the hope that environment will at last effect a change.

In closing, let me urge all mine officials who feel discouraged after making an honest effort to Americanize their foreign-born employees, to observe the effect their efforts have had on the children. I venture the assertion that some improvement will be there observed.

Rosemont, W. a. J. A. H.

INQUIRIES OF GENERAL INTEREST

Air-Cylinder Lubrication

Will you kindly state, in the columns of *Coal Age* what are the essential requirements in the lubrication of the air cylinder of a compressor. There seems to be a variety of opinions in regard to the best lubricant to use for this purpose. I had supposed that a cylinder oil that gave good results in the steam cylinder would give equally good results in the air cylinder of a compressor, until I found by sad experience that it would not. It is claimed by some engineers with whom I am acquainted that soap and water gives as good results in the lubrication of the air cylinder of a compressor as any of the best lubricants on the market.

Indianapolis, Ind. ENGINEER.

There is hardly any subject connected with the industry of coal mining that requires more constant hammering, in the effort to educate new engineers, than the question of the proper lubrication of the air cylinder of a compressor. As this correspondent has learned by experience, the air cylinder is quite a different proposition from that of the steam cylinder, a different lubricant being required in each case.

Much trouble is experienced in the lubrication of the cylinder of any engine, air, gas or steam, unless the lubricant is adapted to meet the special conditions involved in the operation of such engine. A lubricant that will give excellent results in the steam cylinder will fail absolutely when used in an air cylinder. The same is true in respect to gas engines, which require a lubricant of high flash point.

In colliery practice, in air-compression work, one of the chief difficulties arises from the dust commonly drawn into the cylinder with the air. This dust mixed with the oil used to lubricate the cylinder forms a deposit or sediment that obstructs the air ducts and valves, causing the latter to leak, thereby raising the temperature and making more difficult the lubrication. On this account, a lighter oil having a gravity of, say from 31 to 33 Baumé has been found to give better results than an oil of less gravity. In this respect, air compression at collieries, except where the air is thoroughly washed and cleaned before being drawn into the cylinder, may differ from that in other operations.

In general, it may be stated that the points to be emphasized as matters to be avoided in the lubrication of an air cylinder are the following:

1. Avoid excessive feeding of the oil. Too much oil in the air cylinder will generally give more trouble than too little. Experience in operation must determine the rate of feeding, which may vary from two to three drops a minute.

2. Avoid the use of a heavy oil, which unnecessarily increases the friction, while a lighter oil lubricates with far better results. High viscosity of the lubricant in the air cylinder is objectionable, owing both to the increased deposit of a carbon residuum and the greater adherence of the lubricant to the cylinder walls.

3. Avoid the use of an oil having a flashing point lower than 375 deg. F. In this connection, attention has been drawn to the fact that the flashing point of an oil is determined, in the laboratory, under atmospheric pressure, and is considerably higher under the greater pressure in the air cylinder. In this respect, the flashing point of oil is assumed to be affected by pressure in very much the same manner as the boiling point of water, which rises with the pressure.

4. Prevent, as far as possible, the entrance of dust-laden air into the air cylinder. The trouble resulting from this cause is often attributed to the lubricant, and the continued trial of oils and greases affords no relief.

The dust mixed with the oil forms a residuum that frequently lines the walls of the receiver to a depth of 1 or 2 in. The discharge valves become coated and leak, with the result that much of the air is churned back and forth in the cylinder, causing a rise in temperature, and, perhaps igniting the residue deposited in the receiver and air line. The burning out of this residue has, at times, caused the air line to become red-hot, destroying the gaskets and doing other damage.

In the intelligent operation of an air compressor, it can be said that there is little danger of an explosion taking place in the compressor. Instances on record, where explosions have occurred in the cylinder, have generally been shown to have resulted from improper management. A practice of which a few engineers are guilty and which is extremely dangerous, is that of introducing into the cylinder kerosene or a light volatile oil, for the purpose of cutting out the oily film deposited in the air ducts and valves of the machine. Such an oil having a low flashing point, it would be remarkable if the oil or the vapor was not ignited at once and an explosion follow.

Many good engineers in charge of compressors advocate strongly the use of soap and water, which they claim furnishes as good lubrication as the best cylinder oil on the market, without the attending difficulties experienced with many oils. For this purpose, a good quality of castile soap, or one free from acid, should be used. It can be arranged so that the same soap and water mixture can be used over and over again, as it does not deteriorate except when mixed with impure air.

One engineer states that he has never obtained better results, in air-compression work, than when lubricating with a good quality of lubricating grease, introduced into the air inlet from a grease cup. He claims that he found this method more convenient and giving less trouble than any he had ever used.

The proper lubrication of air cylinders is important, and *Coal Age* will be glad to have this subject freely discussed by engineers, who are invited to state their difficulties and the way they have overcome them.

EXAMINATION QUESTIONS

Kansas Firebosses' Examination Pittsburg, May 15, 1918

(Selected Questions)

Ques.—What is a safety lamp? Describe the essential features on which a safety lamp is based.

Ans.—The words, "safety lamp," as used in coal mining, refer to a lamp the flame of which is protected by a wire-gauze chimney, which allows air to enter the combustion chamber of the lamp but prevents the flame of the gas burning in the lamp from passing out and igniting the gas-charged air outside.

The essential features on which the safety of the lamp depends are the following: (1) The complete isolation of the flame, by means of a perfect gauze of standard mesh (784 openings per square inch), which forms the chimney and covers all openings to the combustion chamber of the lamp. (2) The perfect fitting of all the parts of the lamp when these are properly assembled. (3) The proper proportionment, in size, of the combustion chamber and the lamp chimney. (4) Sufficient protection in the upper portion of the lamp, by means of double gauzes, or a gauze cap or a metal shield or both. (5) A steel bonnet surrounding the chimney of the working lamp. (6) A safe non-volatile oil burned in the lamp. (7) The proper handling of the lamp, in gas, by a competent person.

Ques.—What is firedamp? What are the lowest, highest and maximum explosive points of firedamp?

Ans.—In this country the term "firedamp" refers to any inflammable or explosive mixture of gas and air. Methane or marsh gas unmixed with air is sometimes wrongly called "firedamp." But, to enable this gas to fire, it must be mixed with certain proportions of air, which renders it inflammable or explosive according to the proportion of air present in the mixture, and such a mixture is firedamp.

The *lowest explosive limit* of pure methane and air occurs when the proportion of gas to air is 1:13; or when the mixture contains 7.14 per cent. of gas. The *maximum explosive point* of pure methane and air occurs when the proportion of gas to air is 1:9.57 or when the mixture contains 9.46 per cent. of gas. The *highest explosive limit* of pure methane and air is reached when the proportion of gas to air is 1:5, or when the mixture contains 16.67 per cent. of gas.

Ques.—What is afterdamp? What gases are found after an explosion of firedamp at its maximum explosive point?

Ans.—The term "afterdamp" refers to the variable mixture of air and gases that results from and remains after an explosion of firedamp or dust, in a mine. While its composition is quite variable, owing to the varying conditions under which the combustion takes place, the general composition of afterdamp consists of carbon dioxide, (CO_2), carbon monoxide (CO), nitrogen (N_2), together with some unburned methane and air or oxygen.

The explosion of a firedamp mixture, at its maximum explosive point, produces carbon dioxide (CO_2), water vapor (H_2O) and the unburned nitrogen, (N_2) of the air, in which case the combustion is said to be complete. All of the carbon of the methane then combines with the oxygen of the air to form carbon dioxide and all of the hydrogen of the methane combines with the oxygen of the air to form water vapor, while the nitrogen of the air remains unchanged.

Ques.—What is a dangerous atmosphere?

Ans.—A dangerous atmosphere is one that is poisonous to breathe, or unsafe because it is inflammable or explosive or approaches this condition. Also, an atmosphere is dangerous when it is deficient in oxygen, or when the oxygen content falls below the normal per centage (20.9 per cent.)

Ques.—What are the explosive gases found in mines, and how are they detected?

Ans.—The gases that form an explosive mixture with air are methane or marsh gas (CH_4) and carbon monoxide (CO). While olefiant gas (C_2H_4) and hydrogen sulphide (H_2S) are explosive when mixed with air, these gases do not occur in sufficient quantities, in mines, to consider them separately.

Methane or marsh gas is detected, in mine workings, by observing its effect on the flame of a safety lamp. A small percentage of this gas causes the flame to "spire" or lengthen. As the percentage increases, the flame becomes unsteady and increases in volume. This effect depends largely on the quality of the gas and is more observable when olefiant gas is present. In a Davy lamp, a gas cap is observed above the flame of the lamp when 2 or 2½ per cent. of gas is present in the air. The height of this cap increases with the increase in the proportion of gas.

Carbon monoxide, when present in the mine atmosphere, is detected by observing its effect on small caged animals such as birds and mice, which show signs of prostration much quicker than a person exposed to the same atmosphere. This is the safest and most reliable means of detecting the presence of this gas in the mine.

Ques.—How would you carry your safety lamp when entering a known dangerous place in the mine?

Ans.—Proceed slowly and with caution, holding the lamp in an upright position near the roof, stopping at short intervals to make a careful test of the air. To do this the current flowing at the roof must be disturbed, by a slight motion of the hand or by blowing against the roof so that the gas will descend to the lamp, which should be held in an upright position close to the roof, and not turned on the side, as is the practice of some firebosses. Care must be taken never to swing the lamp, and to protect it against strong air currents, especially when advancing against the air.

COAL AND COKE NEWS

Harrisburg, Penn.

The Federal Trade Commission has accepted the proposal of the Anthracite Consumers' League to investigate the cost of anthracite coal, with a view to a reduction in price if the profits are regarded as exorbitant. In a letter to Hon. Frank C. Reese, the Commission declares it will be glad to receive all the information in the hands of the league as to the cost per ton of coal. The league has demanded that the price be reduced in September instead of raised, as coal at present prices is producing big earnings over expenses. One of the practices of the coal companies to which the league particularly objects is that of billing deteriorated coal reclaimed from the refuse banks at prices which obtain for fresh mined coal. It is alleged that the coal from the banks is being produced at a cost of little more than 25c. a ton.

Uniontown, Penn.

Inspection of coke shipments from all regions in the country, with an established basic price for low-grade coke in prospect if that measure does not substantially improve the quality of coke being delivered to the foundries, was inaugurated in the Connellsville coke region following the conference with 200 operators here of Warren S. Blauvelt, coke director for the United States Fuel Administration. R. C. Glazier, of Johnstown, a practical furnace man and coke expert in the employ of the Cambria Steel Co., has been named chief coke inspector and has already assumed his duties at Washington.

Should the projected inspection system not produce the desired improvement in the quality of coke, Mr. Blauvelt told the operators a basic price of $5 per ton would be established for low-grade coke, which would in effect be a penalty of $1 per ton for its foreign content. There will be no change in the fixed price of $6 for coke, he said, but if the two prices are established, the present figure will represent the selling price of first grade coke passed by Mr. Glazier's inspectors.

For some time the fuel administration has contemplated some measure looking toward the improvement in quality, Mr. Blauvelt stated, and told the operators that the recent meeting of the country's steel men in Washington when the steel needs of this country and the Allies were outlined precipitated action. He said that the furnaces were not producing the tonnage of metal in proportion to the quantity of coke delivered and had found after thorough investigation that the trouble lay principally in the quality of the coke.

Charleston, W. Va.

Labor Day coming in the first week of September did not make for a propitious production start for the month, not only because of the holiday itself but because of the aftermath. Nevertheless West Virginia coal men were sanguine that they would not have to contend during September against the paucity of cars which retarded production so much during August. Whatever the claims of the railroads may be as to why there was a decrease in production in the West Virginia fields during August, those in touch with conditions know that it was meager transportation facilities which prevented the industry from going ahead in production. However, as a result of the representations made by production officials in various West Virginia districts, it is believed that most of the West Virginia mines will receive in the future close to a 100 per cent. car supply. At the same time no company will be furnished any more cars than it can possibly load.

Some impetus was given to production in the Fairmont field during the last week in August and the first week in September by a better car supply, but late placing of cars and two holidays—Sunday and Labor Day—tended to make it impossible to get away to a flying start during the month. The district had on Saturday, Aug. 31, 969 cars, which was somewhat in excess of the usual Saturday supply. However, not all of the supply available was placed in time to make full loading possible. Indeed, late placing has brought to a focus the question of what constitutes "cars available," operators contending that cars in yards but not in sight for loading, as it were, should not be classed as available cars. An extra number of cars were asked for Saturday in order that some of the mines might be operated Saturday night but the additional supply was not forthcoming.

In the Kanawha District, Labor Day reduced the usual output a sixth or nearly so, and of course made it impossible to forge ahead at the outset of September. Mines on Cabin Creek were unable to muster their full complement of men for several days after Labor Day. On Coal River Labor Day did not interfere with production, miners going right ahead despite the fact that it was a holiday. Cars were plentiful for several days following Labor Day, but since the railroads had had several days in which to accumulate a supply the operators could not be certain as to whether the supply would be maintained.

With both miners and operators joining in the production movement in the Tug River and Pocahontas regions, a spurt in production was recorded during the week ending Aug. 24, a gain of 8961 tons being recorded. For the period mentioned the total production was 446,507 tons as against 437,546 tons for the previous week. While cars were somewhat more scarce, still only 109 hours were lost because of such a shortage, that loss being met in part by a small margin of a gain in the number of hours worked, the total time the mines worked being 7368 hours. From all causes there was a tonnage loss of 48,592, or something like 7000 tons less lost than for the week preceding. The two districts combined showed a total of 47,714 tons of coke produced.

Birmingham, Ala.

Coal production on Monday, Sept. 2—Labor Day—was up to normal. Miners and mine employees disregarded the great labor holiday, or rather marked it by unusual effort on their part to produce a maximum quantity of coal, and the announcement of their intention to put in a full day's work resulted Saturday, Aug. 31, in an order by local representatives of the Railroad Administration to have all needed cars at the mines Monday, and rail facilities were ample to handle the output.

While there are some mines which reported a loss of a day or two during the week as a result of car shortage, the production for the week ended Aug. 31 promises to be most satisfactory. For the four weeks starting with the week ending Aug. 3 and including the week ending Aug. 24, the coal production in this state has amounted to 421,532 tons a week.

It is estimated that the output at the mines for the last week in August will go 10,000 tons above this figure. If the production can be kept around 431,000 tons a week it would bring the rate of production to approximately 22,412,000 tons for the year. It is believed the maximum production of 433,738 tons recorded during the week ending July 27 will be exceeded. If this is realized it will bring about a recovery in the loss in output suffered during the first six months of the year and provide for a possibility of equalizing the production of last year, which amounted to 20,413,811 tons.

The fact that coal production is being kept at top speed is having a noticeable effect on the coke production in this district, which according to reports this week is holding up remarkably well. The government has started compiling statistics on coke production in this district which will be announced at regular intervals.

Vancouver, B. C.

The price of domestic lump has been raised from $8.80 a ton to $9.50 by most of the retail dealers. This increase, it is assumed, is the result of the recent action of the Canadian Fuel Controller in permitting certain of the Vancouver Island collieries to raise their selling prices. The view taken by the controller on the occasion in question was considered rather unusual, inasmuch as he authorized a maximum selling rate of $6.55 a ton to all the Island mining companies with the exception of the Canadian Western Fuel Co., which was not sanctioned to raise its quotations beyond the maximum which had previously prevailed—namely, $5.80 a ton. The explanation given was that investigation had proved that owing to circumstances over which they had no control, all other collieries were subject to greater production charges than the Canadian Western Fuel Co. and that the latter was the only one which was making what might be considered a fair profit on the capital investment. The Vancouver public, however, takes the position that dealers handling Canadian Western Fuel Co. coal, as well as others, have raised prices and that some must have gone beyond the power given them by the controller when he set their maximum profits at 50c. a ton. It is suggested that an investigation is in order.

The July tonnages for British Columbia are most encouraging, as the figures show that the production is holding with the pace set at the beginning of the year and indicate that there is a good chance that the Province will, when the statistics are compiled at the end of the twelfth month, be found to have outstripped all previous records. Following is the production in tons of the various collieries for the month:

	Tons
Crows Nest Pass Coal Co., Coal Creek	37,992
Crows Nest Pass Coal Co., Michel...	19,407
Corbin Coke and Coal Co., Corbin..	13,454
Middlesboro Collieries, Merritt.....	7,988
Fleming Coal Co., Merritt.....	3,504
Coalmont Colliery, Coalmont.....	347
Princeton Colliery, Princeton.....	3,145
Canadian Western Fuel Co., Nanaimo	61,563
Canadian Collieries (D) Ltd., Comox	46,698
Canadian Collieries (D) Ltd., Extension	18,650
Canadian Collieries (D) Ltd., South Wellington	2,122
Pacific Coast Coal Mines, South Wellington	6,775
Nanoose Colliery, South Wellington	2,285
Granby Colliery, Cassidy's.....	2,718

It will be noted that there are three mines on the producers' list which have not been there for some time, two of which have been newly opened. The latter are the Canadian Collieries' mine at South Wellington, which has 2122 tons to its credit, and the other the Granby Mine at Cassidy's with a production of 2718 tons. These, while comparatively small at present, will grow and no doubt will become a material factor in British Columbia's coal output. The Coalmont Colliery is the other referred to and, although it starts with the modest tonnage of 347 tons for the month, more may be expected of it in the near future.

PENNSYLVANIA

Bituminous

Uniontown—The Connellsville coke region for the week ending Aug. 24 set a new high record for coal production. The tonnage for the week aggregated 716,954 tons, a greater output than has been recorded since the compiling of statistics was commenced by the Fuel Administration. Coal reduced to coke aggregated 335,214 tons, a gain of 11,133 tons, while coal shipments amounted to 214,133 tons, an increase of 24,099 tons. An improved car supply and mild weather conditions were mainly responsible for the excellent showing, but the labor supervising system was also a factor in the increase.

In order that the 200 coal miners in the Connellsville coke region may be supplied with electric power, the War Industries Board, through the local fuel administration, has ordered that all day power be discontinued at nonessential plants in this section. This action makes certain that the mines will receive "juice" and assures a larger output of coal and coke, so necessary to steel manufacture.

Cost sheets from all thin-vein coal operators must be submitted to the fuel administration before any action is taken on the application for an increase in fuel price on such coal in Fayette County. This report was made to the thin-vein operators at a meeting held in Uniontown by the committee named at a previous meeting.

Uniontown—Phillip Colliery, an Italian employed by the Republic Iron and Steel Co., drew $327.25 for 14 days' work, an average of $23.38 a day. Between Aug. 16 and 31, he loaded 374 cars. He is 5 ft. 4 in. in height, weighs 160 lb. and is married. Until this record he was averaging about $80 per week.

Berlin—Harry Pyle, a coal miner, is believed to have broken all records of earnings in war-times by drawing $516.10 for 26 consecutive days' work in the mines. This miner works in the thin vein of coal, where only pick mining is pursued. Pyle is employed at the Blande mine of the McGregor Coal Co. During a period of 26 days, beginning July 16, and ending Aug. 15, Pyle mined 410 long tons, excavated 44 yards of entry, for which he received $4, and put in two hours on outside labor.

Brownsville—The Elliott Estate tract of coal properties, totaling about 300 acres, has recently been acquired by Julian Kennedy and associates at a price said to be about $2200 an acre. It is understood that the new owners will operate the property.

Fredonia—A vein of coal has been located on the Sherman Harsh farm, near here. Stoneboro parties have secured leases on this and adjoining farms and are having tests made to sink a shaft. The vein is reported to be from four to six feet thick.

Anthracite

Minersville—The Lytle Coal Co. has started a series of first-aid contests. This marks the ninth annual drill of its kind, the contests being held after quitting time at the various collieries during the month of September.

Hazleton—Figures made available on Sept. 4 show that fuel production for August in the Lehigh region was considerably ahead of that of the same month last year. Officials of the Lehigh Valley Coal Co., the largest producer in the field, estimate that its total would run 25,000 tons over August, 1917. The daily output of the valley now averages between 8500 and 9000 tons.

Harleigh—Some of the women are helping their husbands load coal from the abandoned slate banks at nearby collieries in efforts to increase the output of anthracite. They are doing the work voluntarily in order that the monthly pay envelope may run above the usual average and at the same time are giving the Government a lift.

Shenandoah—The Locust Mountain Coal Co. has had plans drawn for a number of 1½-story residences for employees at its properties. The structures will be of the three-family type.

WEST VIRGINIA

Charleston—Following complaints of the Kanawha Coal Operators' Association to the Fuel Administration for the lack of cars in the Kanawha Valley mining section, the Chespeake & Ohio R. R. has been instructed to keep a supply of cars on hand at the mines at all times.

Elkins—Extensive improvements have been made at the plant of the Edward O'Toole (trustee) Co.'s plant in Barbour County, the company having installed a generating plant, two mining machines, a 13-ton locomotive, electric pump. New mining cars have also been added to its equipment.

Arden—The Lee Collieries Co. will extend its operations by opening another mine a mile or so from the company's present operation at Arden, and as a forerunner of operations there will put up miners' houses. At the Arden plant a new tipple has just been completed and put in commission.

Buckhannon—In addition to building a number of houses for miners, the Buck Coal Co. is putting in new scales at its Lorentz plant. A new store and office building has also been added to the plant.

Clarksburg.—In connection with the opening of a drift mine in Harrison County by the Catherine Coal Co., it is learned that the company plans to have a mine with a capacity, when completed, of 50,000 tons per year, work having already been started on this plant, which will be ready for operation by Oct. 1st. The superintendent of the company is C. S. Hornor, of Clarksburg.

Philippi—Coal is now being shipped from the plant of the Wolf Coal Co., located near this place. Construction work was recently completed on this plant.

Progress is being made by the Buckeye and West Virginia Coal Co. at Lorentz in the installation of new machinery under the direction of Superintendent O. M. Malcolm.

The Meadowvale Coal Co. whose plant is at Arden, will be ready for operations within a short time, the plant having been completed. A number of houses for miners have also been built.

The Ford Run Coal Corporation, with a plant at Meriden, has erected a tipple at its No. 6 mine where it will begin producing coal in a short time. Lee J. Sandridge is general manager, being also largely interested in the company.

Grafton.—The Gaymont Coal Co. has decided to depend upon its own power and the directors of the company have authorized the construction of a power plant at Bolder, where the company has its plant. The operating official in charge is B. C. Cence.

Just as soon as a siding which is now being laid is completed, the Cordell Coal Co. hopes to be able to begin the shipment of coal from its new plant at Wilt. At this point the company has a thick vein of Pittsburgh coal to mine. J. J. Delaney will be in charge of operators.

ALABAMA

Birmingham—The Big Four Mines, near North Birmingham, have been acquired under lease by the Sandstone Coal Mining Co., operating in this district. The present capacity of the plant, aggregating 125 tons a day, will be increased, and extensive development work inaugurated. W. M. Holt is president.

Birmingham—John Pennington, white, and Jack Jones, colored, were killed, and a number of other mine employees placed in jeopardy, when the Mary Lee mine of the Alabama Co. was flooded on the afternoon of Sept. 2. A heavy rain approximating a cloudburst swelled a branch near the mouth of the slope beyond its banks, the water pouring into the slope and manway and carrying everything before it. All other mine workers are thought to have been rescued. The slope tracks and retaining walls at the entrance to the mine were inundated and washed away, as was also the approach to the manway, the property damage amounting to several thousand dollars. At the time of the accident most of the employees, numbering about 400, had finished their tasks and come to the surface.

Delmar—The Glen Mary Coal Co., operating in the Natural Bridge section, has acquired about 400 acres of land adjoining its properties, and plans for extensive development work for increased output.

KENTUCKY

Greenville—O. C. Evans, operating local coal properties, is planning for the installation of new electric equipment at his mine.

OHIO

Martins Ferry—Work is progressing in the opening of the new mines of the Y. & O. Coal Co. on Little Short Creek, west of Rayland on the Wheeling & Lake Erie R. R. The tracks leading to the mines are being graded and two steam shovels are at work cutting away the hillside and filling in the hollows. Several miles of track will be necessary to reach the proposed openings. A town is to be laid out on the site and already several houses are under construction.

Gloucester—Fire recently destroyed all the buildings at the Hunterdon mine of the Ohio Valley Collieries Co.

Coshocton—George Sloan, of Zanesville, who recently purchased the Edward Nash farm near Adamsville from G. H. Lapp, has sold the property to Lloyd Amore of Coshocton, who expects to begin work on the development of a coal mine.

ILLINOIS

Alton—Prolonged drought, only recently broken, enabled the reclamation of abandoned workings in Coal Branch, on the outskirts of Alton. These plants had been abandoned for several years on account of the encroachment of water. During the drought it was discovered that the water had receded, and arrangements have been made to resume operation of several of the pits. When they were abandoned they could not be operated profitably, both on account of the comparatively limited output and the water difficulties, but money can be made out of them now by supplying the local demand. W. T. Davies has a force of men getting pits on the James Wilson property ready for producing. Precautions will be taken against renewed flooding of the workings.

Hillsboro—A report that after Sept. 1 the mines in this vicinity would not be permitted to supply local consumers caused a run on the mines in the closing days of August. Vehicles of every description were pressed into service by anxious consumers, who stood in line for hours at the mines. The mine managers say, however, that they have not yet received orders to withhold coal from local consumers.

IDAHO

Coeur D'Alene—Work has been started by the Oregon Short Line Railway Co. on the construction of a 12-mile branch from its main line to the coal mines of the Brown Bear Coal Co., in Teton County. The branch will run from Driggs to Teton. R. C. Talbot is manager for the coal company.

WASHINGTON

Chehalis—D. W. Proebstel, electrical engineer for the Portland Railway, Light and Power Co., Portland, Ore., is here while superintending the installation of electrical machinery at the plant of the Superior Coal Co. The equipment will consist of an electrical hoist, said to be the largest in the state, an electrical locomotive to haul the coal to the foot of the 1600-ft. entrance slope, and an electrically driven conveyor to the tipple. T. R. Campbell is manager of the mine and states that when the equipment is installed the operation will be producing about 400 tons a day.

Seattle—The school board has accepted the bid of the Hyde Coal Co. at $4 per ton for 1250 tons of steam coal and that of the Roslyn Coal Co. at $3.30 per ton for 1000 tons of mine-run.

Spokane—Preliminary development work is being undertaken by the Colville Valley Coal Co. on its property, which consists of 320 acres at Valley, near this city. The coal vein is contained within sandstone and shales. A shaft 300 ft. deep has been driven on the vein, which is 6 ft. wide, and according to the company geologist contains 10 per cent. moisture, 14 per cent. ash, 37 per cent. volatile combustion and 38 per cent. fixed carbon. Frank Weatherwax, of Valley, is president of the company; A. N. Cantril, secretary-treasurer. The company is considering putting in a 60-ton capacity briquetting plant.

Tacoma—An explosion at the Burnett mine of the Pacific Coast Coal Co. on Aug. 28 cost 12 miners their lives and seriously injured three others, 170 who were at work in the mine escaping unhurt. At this writing the cause of the explosion is undetermined. It is believed that the explosion, which occurred at 4:30 p. m., was due either to gas or a "shot" of dynamite that went wrong. State Mine Inspector Bagley believes that dust was undoubtedly a contributing factor in either case.

Foreign News

Victoria, B. C.—During the first six months of the present year coal production in British Columbia has reached the total of 1,375,230 tons, or 247,922 tons in excess of that produced for the same period of last year. The tonnage produced in the three districts is as follows: Crowsnest Pass, 404,472 tons. Nicola-Princeton, 109,483 tons; Vancouver Island, 861,314 tons.

Personals

J. F. Healy, of Huntington, W. Va., for nearly three years allotment commissioner for the Chespeake & Ohio, has resigned to become manager of the Reliance Coal and Coke Co., of Kentucky, with office at Glomar, near Hazard. Mr. Healy will continue to reside in Huntington.

F. K. Day, chief engineer of the West Virginia division of the Consolidation Coal Co., of Fairmont, W. Va., has been granted a furlough for the duration of the war. He has been appointed assistant production manager for northern West Virginia by James B. Neale, director of production of the Fuel Administration.

W. T. Lucey, of Harrisburg, Penn., has assumed charge of the Birmingham (Ala.) Mine Rescue Station of the United States Bureau of Mines, succeeding W. T. Burgess, who has been superintendent of the station for some time. Mr. Burgess resigned recently to accept the position of superintendent of the Belle Ellen mines of the Bessemer Coal, Iron and Land Co.

Austin Riggs, assistant division engineer of the West Virginia division of the Consolidation Coal Co., of Fairmont, W. Va., has been appointed division engineer, to succeed F. K. Day, who has been furloughed to the United States Fuel Administration,

as mentioned elsewhere in these columns. Mr. Riggs has been in the employ of the Consolidation company for seventeen years. The position of assistant division engineer will not be filled at this time.

Obituary

William Cameron, Secretary of the St. Louis Coal Traffic Bureau, and chairman of the freight committee of the eastbound lines, died a few days ago at Denver, Colo., where he had gone in the hope of benefiting his health. He was stricken in July and spent a month in a sanitarium before going to Denver. The body was brought to St. Louis, Mo., for interment. Mr. Cameron had a wide acquaintance among coal men.

Thirty-Sixth Annual Coal Report of Illinois. Department of Mines and Minerals, 1917. Unillustrated, 302 pp., 6 x 9 inches.

Report of the Department of Mines of Pennsylvania. Part I—Anthracite, 1916. Commonwealth of Pennsylvania. Unillustrated, 900 pp., 6¼ x 9¼ inches.

Report of the Department of Mines of Pennsylvania. Part II—Bituminous, 1916. Commonwealth of Pennsylvania. Unillustrated, 1404 pp., 6¼ x 9¼ inches.

Monthly Statement of Coal Mine Fatalities in the United States, May, 1918. Compiled by Albert H. Fay. Department of the Interior, Bureau of Mines. Unillustrated, 23 pp., 6 x 9 inches.

The Tars Distilled from Bituminous Coal in Hand-Fired Furnaces. By S. H. Katz. Department of the Interior, Bureau of Mines. Technical Paper 195. Illustrated, 17 pp., 6 x 9 inches.

A Convenient Multiple-Unit Calorimeter Installation. By J. D. Davis and E. L. Wallace. Department of the Interior, Bureau of Mines. Technical Paper 91. Illustrated, 47 pp., 6 x 9 inches.

Annual Report on the Mineral Production of Canada During the Calendar Year 1916. John McLeish, B. A., Chief of the Division of Mineral Resources and Statistics. Canada Department of Mines, Mines Branch. Unillustrated, 343 pp., 6¾ x 9¾ inches.

Methane Accumulations from Interrupted Ventilation, with Special Reference to Coal Mines in Illinois and Indiana. By Howard I. Smith and Robert J. Hamon. Department of the Interior, Bureau of Mines. Technical Paper 190. Illustrated, 42 pp., 6 x 9 inches.

Trade Catalogs

Jeffrey 35 B—Shortwall Mining Machine. The Jeffrey Manufacturing Co., Columbus, Ohio. Bulletin 241. Pp. 12; 6 x 9 in.; illustrated. Features the latest type of Jeffrey shortwall coal cutter.

Jeffrey Electric Rotary Coal Drills. The Jeffrey Manufacturing Co., Columbus, Ohio. Bulletin 243. Pp. 12; 6 x 9 in.; illustrated. Describes the A-5 electric rotary drill for drilling in any material which can be penetrated with an auger bit.

Sullivan Straight-Line Air Compressors, Sullivan Machinery Co., Chicago, Ill. Circular 58-W. Pp. 30; 6 x 9 in.; illustrated. Instructions for the installation and operation of classes WA-3 and WA-4 (steam driven) and WG-3 and WG-4 (belt driven) compressors.

The Lincoln Wheel for Mine Cars. Lincoln Steel and Forge Co., St. Louis, Mo. Bulletin 102. Pp. 12; 9 x 11⅞ in.; illustrated. This bulletin is in convenient form for filing and calls attention to the many points which make the Lincoln wheel meet the approval of the operator.

Condensers, Pumps, Cooling Towers, Etc. Wheeler Condenser and Engineering Co., Carteret, N. J. Bulletin 112-A, pp. 32; 8 x 10½ in.; illustrated. Describes condensers and condensing machinery. One page is devoted to the Wheeler feed water heater and two pages to multiple effect evaporators and dryers.

C-H Iron-Clad Solenoids. Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Booklet F. Pp. 4; 8½ x 11 in.; illustrated. Describes solenoids particularly adapted for operating brakes used in connection with crane, elevator and hoist motors. Booklet lists four sizes and gives the stroke, gross pull, dimensions, weights and other interesting data.

Bulletins. Electrical Engineers Equipment Co., Chicago, Ill. Illustrated, 8 x 11 in. The loose-leaf bulletins contained in this binder give a complete description of all the products manufactured by this company. All information and illustrations have been prepared with the idea of making the selection of the proper apparatus as simple as possible for prospective buyers.

Brake for Uphauls for Mines. W. J. Mow, Grass Valley, Cal., 1,274,071, July 30 1918. Filed May 18, 1917. Serial No. 169,555.

Water Back Construction for Furnaces. F. A. Hurlburt, Kansas City, Mo., 1,269,083. June 11, 1918. Filed June 24, 1916. Serial No. 105,725.

Self-Feeding Device for Furnaces. J. H. Turnbull, Edmonton, Alberta, Can., 1,262,876. Apr. 16, 1918. Filed May 16, 1917. Serial No. 169,119.

Mining Machine. E. C. Morgan, assignor to American Morgan Co., Chicago, Ill., 1,271,197. July 2, 1918. Filed May 28, 1904. Serial No. 210,174.

Boiler Furnace. A. C. Mott, Jr., assignor to Abram Cox Stove Co., Philadelphia, Penn., 1,262,229. Apr. 9, 1918. Filed July 10, 1917. Serial No. 179,678.

Chain Grate Stoker. W. W. Holland, J. R. Carringer and W. Bacheldor, Woodriver, Ill., 1,268,845. June 11, 1918. Filed Jan. 12, 1918. Serial No. 211,528.

Roller Bearing Mine Car Wheel. J. L. McDowell, assignor to American Car and Foundry Co., New York, 1,256,149. Feb. 12, 1918. Filed Sept. 5, 1917. Serial No. 189,861.

Forced Draft Furnace Grate. L. H. Simmons, assignor to Simmons Forced Draft Co., Goldsboro, N. C., 1,270,065. June 18, 1918. Filed Jan. 30, 1917. Serial No. 145,442.

Feeding Mechanism for Gas Producers. C. W. Lummis, assignor to Morgan Construction Co., Worcester, Mass., 1,270,962. July 2, 1918. Filed Mar. 10, 1916. Serial No. 83,396.

Roller Bearing Mine Car Wheel. F. Helmick, assignor to Helmick Foundry and Machine Co., Fairmont, W. Va., 1,270,155. June 18, 1918. Filed Apr. 16, 1918. Serial No. 228,934.

Shaking and Dumping Device for Furnace Grates. H. W. Dockray, assignor to Dockray Brass and Iron Co., Zanesville, Ohio, 1,270,126. June 18, 1918. Filed Nov. 17, 1917. Serial No. 202,619.

Industrial News

Barbourville, Ky.—The Trace Branch Coal Co. has increased its capital from $1500 to $5000.

Louisville, Ky.—The Collins Mining Co., of Lackey, has increased its capital from $20,000 to $50,000.

Chicago, Ill.—The Lakewood Engineering Co. has opened new offices in Chicago in the Lumber Exchange Building.

Richmond, Va.—The Bens Run Coal Co. has been incorporated with a capital of $50,000 to develop coal mines at Hyer in Braxton County.

Prestonsburg, Ky.—The Anchor Coal Co. has increased its capital stock from $10,000 to $20,000, to take care of planned improvements to its workings.

Louisville, Ky.—The Walnut Coal Co. has been incorporated with a capital of $3000. The incorporators are W. F. Burwinkle, J. S. Miller and R. E. Godon.

Madisonville, Ky.—The Richland Coal Co. has been incorporated with a capital of $9000. John G. Salmon, Tom Logan and C. M. Logan are the incorporators.

Pineville, Ky.—The Greasy Gap Coal Co. has been incorporated with a capital of $25,000. The incorporators are I. Glickman, Lewis Jones and Morris Euster.

Columbus, Ohio—The S. M. Hudson Coal and Coke Co., of Steubenville, has been incorporated with a capital of $200,000. S. M. Hudson is the principal incorporator.

Indianapolis, Ind.—The Lincoln Coal Co., of Lincoln City, has been incorporated with a capital of $15,000. David Ellison, C. F. Wilson and M. P. Dixon are the incorporators.

Louisville, Ky.—The Farris Coal Co., of East Bernstadt, has been incorporated with a capital of $2000. The incorporators are W. R. Ballou, B. B. Farris and James Farris.

Dover, Del.—The Garfield Coal Co. has been incorporated with a capital of $100,000. The incorporators are John C. Draper, C. L. Rimlinger and F. A. Armstrong, of Wilmington.

Big Chimney, W. Va.—Improvements on a rather extensive scale will be made to the plant of the Empire Coal Co. at this place, just as soon as material and equipment can be secured.

Louisville, Ky.—The Uniontown Coal Co., of Henderson, has been incorporated with a capital of $100,000. The incorporators are C. C. Potter, Dandridge Spotswood and J. H. Turner.

Spokane, Wash.—The Colville Valley Coal Co. has filed articles of incorporation with a capital of $100,000. J. E. Rudersdorf, A. W. Doland and A. N. Cantrell are the incorporators.

Cleveland, Ohio—The Elm Coal Co. has been incorporated with a capital of $1000. E. L. Maag, Frank H. Maag, H. W. Stohlmann, Fred Maag and John H. Reik are the incorporators.

Philippi, W. Va.—The Byrer Coal Co. is preparing to enlarge its capacity by the installation of new equipment, the company also having under construction more houses for miners.

Louisville, Ky.—The Baird Jellico Blue Gem Coal Co., of Gatliff, has been incorporated with a capital of $1000. The incorporators are I. C. Bryant, L. D. Baird and Charlotte Baird.

Oklahoma City, Okla.—The Banner Coal Co., of McAlester, has been incorporated with a capital of $10,000. W. E. Beaty, R. E. Jones, L. C. Cramer, all of McAlester, are the incorporators.

Charleston, W. Va.—The Gauley Mountain Coal Co. has added to its equipment by purchasing two rotary conveyors among other new machinery. R. H. Harris is the manager at this operation.

Louisville, Ky.—The Elkhorn and Jellico Coal Co., of Whitesburg, has been incorporated with a capital of $50,000. M. K. Marlowe, P. E. Marlowe and James Marlowe are the incorporators.

Louisville, Ky.—The Kentucky River Mining Co., of Cannell City, has filed articles of incorporation with a capital of $3600. W. E. Bach, W. L. Day and T. J. Barr are the incorporators.

Tulsa, Okla.—The Gunther City Coal Mining Co., of Tulsa, has been incorporated with a capital of $150,000. The incorporators are S. A. Gaskill, of Claremore, A. C. Gunther and E. A. Vernon, of Tulsa.

Columbus, Ohio—The Packard Coal Mining Co., of Columbus, has been incorporated with a capital of $50,000. The incorporators are M. L. Yuster, Richard Patton, E. E. Fox, W. J. Etchen and C. F. Bookman.

Charleston, W. Va.—With a view to extending operations the Long Branch Coal Co. has trebled its capital stock from $50,000 to $150,000. The operation of this company is at Long Branch, Fayette County.

Canton, Ohio—The Albert Coal Mining Co. has been chartered with a capital of $95,000 to mine coal. The incorporators are John D. Gardner, Charles K. Welch, W. J. Bentram, John O. Cole and A. R. Milner.

Pittsburgh, Penn.—The Charles T. Topping Machinery Co. has merged its interests with the Pittsburgh office of the Lakewood Engineering Co., Cleveland, Ohio, manufacturers of construction plant and industrial haulage.

Charleston, W. Va.—The American Eagle Colliery Co., recently incorporated with a capital of $600,000, is planning for the development of coal properties in this vicinity. L. V. Black and George S. Couch head the company.

Louisville, Ky.—The Central Kentucky Block Coal & Mineral Co., of Hawesville, has filed articles of incorporation with a capital of $200,000. Charles E. McDavitt, Harry Myers and Stanley Allen are the incorporators.

Indianapolis, Ind.—The Elk Run Coal and Mining Co., of Hymera, has been inporated with a capital of $150,000. The incorporators are George E. Elkins, Joseph L. Hampson, Forrest Chenoweth and Lueppo D. Buenting.

Nelsonville, Ohio—The Athens-Hocking Coal Co. has been incorporated with a capital of $35,000 to mine and sell coal. The incorporators are Frank Brown, A. P. Stedem, Rudolph Brown, J. W. Wion and Ira Blackstone.

Cleveland, Ohio—The P. & M. Coal Co. has been incorporated with a capital of $75,000 to mine and sell coal. The incorporators are Philip M. Platten, S. H. Holding, Tracy H. Duncan, May E. Gardner and B. M. Parker.

Salem, Ore.—The Fern Valley Coal Co., of Medford, has been incorporated with a capital of $5000. The incorporators are Leonard Carpenter, Frederick H. Cowles, Alfred S. V. Carpenter, Waldo W. Williard and Lincoln McCormack.

Cincinnati, Ohio—The Lawrence County Coal and Clay Co., of Ironton, has been incorporated with a capital of $10,000. Chester Pendleton, Huldah Brucklacher, A. E. Kerns, Garnet Roberts and Grover C. Mills are the incorporators.

Corinth, W. Va.—The Freeport Coal Co. is planning for extensive improvements at its plant to increase the present capacity. The company recently filed notice of an increase in its capitalization from $25,000 to $100,000, to provide for this work.

Madisonville, Ky.—The Finley Coal Co., capital $10,000, has been chartered at Madisonville to operate coal mines. The incorporators are Thomas E. Finley, Mrs. Finley and Dr. C. B. Johnson, the latter of Earlington, these three holding all of the stock.

Louisville, Ky.—The Union County Mining Co. has been incorporated with a capital of $200,000. Fred Reiss, William Jarvis and R. F. Peters are the incorporators.

Charleston, W. Va.—The Kanawha Collieries Co., which will mine coal in Nicholas County, perfected its organization this week by electing W. G. Conley, president; Edward Gebhart, vice president and H. P. Tompkins treasurer and general manager.

Princeton, Ky.—The Betsey Mining Co., recently incorporated with a capital of $20,000 by J. M. Phillips, and others, plans operations on a 43-acre tract at Crider. The concern will install open mining machinery, including pumps, boiler, compressors, washer, etc.

Charleston, W. Va.—The Cass Hill Coal Co. has been incorporated with a capital of $50,000 to develop coal lands in Cass district, Monongalia County. The incorporators are Bernard J. Lynch, William F. Coal, Carl C. Hetzel, G. Howard Hetzel and Robert L. Stallings.

Charleston, W. Va.—The Big Bottom Coal Co. has been incorporated with a capital of $50,000 to develop coal lands in Malden District, Kanawha County. The incorporators are J. S. Cheyney, H. S. Cheyney, James Raisbeck, M. W. Raisbeck and T. S. Clark.

Birmingham, Ala.—The Phillips Mining Co. has been incorporated with a capital of $75,000 and will conduct mining operations at Sipsey, Walker County, Ala. The new operation is reached by a branch line from the Frisco which serves the Sipsey and Empire mines.

San Francisco, Cal.—A sum approximating $7500 has been collected by State Fuel Administrator Albert E. Schwabacher, from the retail coal dealers of the state for overcharging. This sum will be turned over to the National Red Cross, according to the plans of Mr. Schwabacher.

Clarksburg, W. Va.—The Diamond Fuel Co., of Clarksburg, has been incorporated with a capital of $50,000 to develop a coal area in Simpson district, Harrison County. The incorporators are J. Edgar Long, Carl E. Hornor, Charles B. Johnson, Wayne B. Hornor and Paul E. Reutter.

Charleston, W. Va.—The Ohio Valley Fuel Co. will have a small operation in Brooke County. The headquarters of the company will be at Wellsburg. The company is capitalized at $10,000 with J. K. Wells, Nera Wells, Lillian S. Wells, S. G. Wells and Millard Wells as incorporators.

Birmingham, Ala.—An interesting tabulation has been made by local coal interests showing the increase in production in the state during the past months. The weekly averages of coal production since April are: April, 353,409 tons; May, 371,268 tons, June, 371,214 tons; July, 406,233 tons; and August, 421,631 tons.

Charleston, W. Va.—Coal lands in Malden District of Kanawha County will be developed by the Buffalo-Kanawha Coal Co. of Buffalo, N. Y., which has taken out a West Virginia charter, with an authorized capital of $150,000. The incorporators are George Carson, E. E. Johnston, W. H. Farnsworth, M. E. Preisch and I. S. Given.

Henryetta, Okla.—The Block No. 1 Coal Mining Co. has been organized and charter has been filed with Secretary of State Lyon at Oklahoma City. The company is capitalized at $125,000 and will develop coal lands known as Block No. 1. The incorporators are Barclay Morgan, C. H. Lockhart and James Hepburn, all of Henryetta.

Charleston, W. Va.—A general coal mining, selling and shipping business will be done by the Sewlmont Coal Co., just chartered with an authorized capital of $150,000. This company was chartered by J. W. Graham, E. F. Graham, W. A. Charlton, C. B. Cottle and J. Q. Hutchinson. The company will have its operation in Fayette County.

Frankfort, Ky.—The Court of Appeals has recently handed down a decision of interest to coal interests in this section, in the case of the Lawrence Tierny Coal vs. Smith, guardian. The court holds that a minor's land may be leased for coal or other minerals by an order of the Court, but that such lease becomes void when the minor becomes of age.

Fayetteville, W. Va.—Organized with a capital stock of $300,000, the Sunrall Coal Co. incorporated by some of the leading citizens of Fayette County, will operate coal mines in that county just as soon as all Government requirements can be met. The incorporators are Dr. Gory Hogg, C. B. Hogg, C. W. Dillon, former State Tax Commissioner, J. P. Stevens and E. L. Nuckolls.

Newark, N. J.—A new coal briquet manufacturing plant to cost about $150,000 will be erected by the Burnrite Briquet Co., 142 Broadway, New York, on property at Alpine St. and Avenue A, recently acquired. The initial works will consist of a group of buildings for manufacturing, handling, loading, etc. The Mashek Engineering Co., 90 West St., New York, is engineer for the company.

Philadelphia, Penn.—The Lehigh Coal and Navigation Co. has awarded contracts to the Dodson Realty Co., Bethlehem, Penn., for the erection of a number of new homes for employees at its different properties. Ten double residences and a large boarding house will be constructed at Seek, Schuylkill County; and twelve double residences, each 2½ stories, 30 x 50 ft., will be located at Kaska Williams, Penn.

Birmingham, Ala.—Ammonia naphtha and other coke byproducts will be manufactured at Boyles, near here, by the Birmingham Coke and Byproducts Co. The plant will cost $3,000,000 and manufacture its products for use in the Government nitrate plant at Sheffield, the War Department having contracted for the output of the new plant. The daily consumption of coal will be 1000 tons with an output of 700 tons of coke.

New York, N. Y.—The Quigley Furnace Specialties Company, New York, has secured the contract for a powdered coal plant from the Whitaker Glessner Co., Beech Bottom Works, West Virginia, to furnish four tons of powdered coal fuel per hour to supply 20 furnaces for heating 6-in. shell forgings. This equipment is arranged for large extensions for future applications in other departments in the mills, including boilers.

Dallas, Tex.—Marked development of the coal mines in western Texas is reported as a direct outgrowth of the continued drouth throughout that section which has driven many of the farmers from their homes in search of other employment. Many of these drouth refugees are finding work in the mines in Young and adjoining counties, and a greatly increased coal output is now reported. Numerous new mines are being developed and operations are being carried on on a larger scale than heretofore.

Toledo, Ohio—A slight falling off in tonnage for lake shipment was noted during the week ending Aug. 31 as compared with some former weeks. The falling off is not considered serious, however. The Hocking Valley docks during the week mentioned loaded 180,878 tons as compared with 199,413 tons the previous week, making a total of 2,862,289 tons loaded for the season. The Toledo & Ohio Central docks during the same week loaded 81,000 tons as compared with 90,000 tons the previous week. The total for the season is 1,291,000 tons.

Buffalo, N. Y.—The Buffalo-Kanawha Coal Corporation has been organized here with capital stock of $150,000. The company owns mines in the Campbell Creek valley, near Charleston, W. Va. Six openings have already been made and coal is ready to ship as soon as the railroad spur is finished. The coal goes by barge down the Kanawha River after a short rail haul. Capacity of 500 tons a day is promised in six months. E. G. Johnson is president; G. A. Corson, vice president and manager; O. W. Davenport, secretary, and W. H. Davenport, treasurer, all of Buffalo.

Charleston, W. Va.—The annual meeting of the Kanawha Coal Shippers Association on Aug. 30 was featured by a banquet at the Kanawha Hotel, new officers being elected and the executive committee enlarged. The roster of officers and of the executive committee as now constituted is J. R. Thomas, of the Carbon Fuel Co., chairman; M. H. Tomb, secretary and treasurer. Executive Committee—J. R. Thomas, Quinn Morton, John L. Dickinson, J. C. Blair and F. B. Stewart, the last two being the new members of the committee. Voting to become affiliated with the West Virginia Coal Association, the Kanawha organization selected C. A. Cabell general manager of the Carbon Fuel Co., as a member of the executive committee of the State Association.

Seattle, Wash.—Judgment in the sum of $2,009,242, including $20,000 in attorney's fees, has been awarded by Judge C. M. Easterday at Tacoma, Wash., in favor of W. V. Rinehart, as trustee for Lindeberg, Inc., against the American Coal Co. and the Southwest Coal Co. as the result of action brought to foreclose on a mortgage given by the coal companies to float $1,500,000 bonds. The court has ordered the sale of the mines to satisfy the judgment. The property of the coal companies lies in or near Morristown, Wash. A review of the case shows that the American Coal Co. executed 3000 negotiable mortgage bonds on Mar. 1, 1912, aggregating $1,500,000, and to mature Mar. 1, 1942. The bonds were certified by the Seattle Trust Co., the trustee named, and are now owned by Lindeberg, Inc. The bonds provide for the payment of interest at the rate of 5 per cent. semi-annually, interest coupons being attached. The interest, however, was not paid, resulting in the foreclosure.

MARKET DEPARTMENT

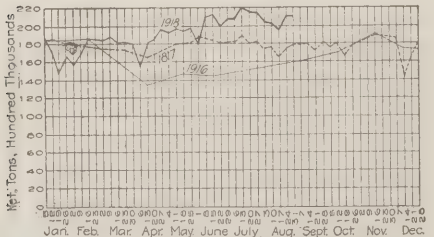
Weekly Review

Production of Bituminous Not Equal to Demands—Whether Mines Will Make Up Deficit During Coal Year Depends on Railroads and Labor—Conservation and Curtailment Watchwords of Fuel Administration—Anthracite Output Breaks Record—Lake Shipments Show Betterment

THOUGH 1,586,000 net tons more of soft coal was produced during the week ended Aug. 31 than was mined during the corresponding week of 1917, yet the output for the last week in August just closed—12,642,000 net tons—was considerably below the mean requirements set by the Fuel Administration as necessary to meet essential needs. Again it must be emphasized that there will not be enough soft coal produced this year to satisfy all demands. Not only are nonwar industries being divorced from their fuel supply, but it is highly problematical if even the so-called war industries will be enabled to keep their fires burning with the intensity necessary to carry on their part of the recently magnified war program. Already more than 13,000,000 net tons behind for the coal year, the soft coal mines must produce at the rate of over 12,000,000 net tons a week for every week until Mar. 31, 1919, if the goal of 628,000,000 net tons of bituminous coal required to meet the country's needs is to be attained.

Are the soft coal mines equal to the task? The answer is both yes and no. Yes, if the railroads live up to the promise made by Mr. McAdoo that the movement of cars to and from the mines will suffer no delay in the future, and the miners labor efficiently for at least eight hours a day, six days a week. No, if Mr. McAdoo's promises of an improved car supply fail to materialize, as has so often proved the case in the past, or the miners lose sight of the larger national interests to further selfish ends by working half-heartedly, or only when the spirit moves them.

With the approach of cool weather also come recollections of the deplorable transportation conditions from which the country suffered last winter. Inadequate motive power, broken down rolling stock, poor track, depleted repairshop forces—why continue the harrowing details? The question is, Are the railroads in shape to meet similar conditions if they should arise this winter? It is like flying in the face of Providence to assume that the coming winter will be less severe than that of last year, as seems to have been done by the Railroad Administration to judge from recent statements emanating from that quarter. True, it is human nature to hope for the best, but at the same time it is the better part of wisdom to prepare for the worst.



Unlike the Railroad Administration, the Fuel Administration deals only with actualities. It is going ahead constructively on the assumption that there will not be coal enough for all. The Fuel Administration is not attempting to fire the furnaces of the country's industries next winter with the empty promises of today. Curtailment and conservation are Dr. Garfield's watchwords, and underlying them both is the thought that war industries must not cease to function for lack of fuel. Toward the accomplishment of this end, fuel experts have been busily engaged in devising practical ways and means by which coal can be saved. For example, by the elimination of wasteful practices in the power plants of the country millions of tons of coal will be conserved. The domestic consumer, too, by means of pamphlets and other mediums, is being taught how to obtain the greatest efficiency from every pound of coal shoveled into the furnace, and sections of the country which had been under the impression that they could burn only certain grades of coal, which had to be shipped to them from distant mines, have been shown that they could burn with equal efficiency coal produced by mines which were at their very doors.

No such gloom as surrounds the bituminous industry is discernible in the anthracite region, though at this writing rumors of a strike in the anthracite field are rife. Undoubtedly a way will be found to settle or adjudicate the questions at issue in the hard coal region, as a let up in the production of anthracite at this time would result in suffering for a large majority of those who live on the Atlantic seaboard. During the week ended Aug. 31 a total of 2,259,715 net tons of hard coal was produced, which is the greatest output recorded during the present calendar year. During the period from April 1 to July 31, the actual distribution of the domestic sizes of anthracite virtually equaled the allotments made to the different states. The total production of hard coal for the coal year to date is estimated at 44,028,000 net tons.

Coal is moving to the lakes, for transshipment to the Northwest, in much better volume than heretofore. Shipments for August were 4,805,049 net tons, which is just under the mark of 4,900,000 net tons set by the Fuel Administration for the month. Thus far this season shipments to the lakes are approximately 1,089,000 net tons behind.

WEEKLY COAL PRODUCTION

The output of bituminous coal in the United States during the week ended Aug. 31 was approximately the same as the week preceding. Estimates place production during this week at 12,642,000 net tons, as against 12,620,000 net tons during the week of Aug. 24 and 11,056,000 net tons during the corresponding week of 1917. The average production per working day for week ended Aug. 31 is estimated at 2,107,000 net tons, an increase over the corresponding week of last year of 14 per cent. and over the average daily requirements for the coal year of 4.7 per cent. The schedule of the Fuel Administration, however, calls

for an increased rate of producing during the six months beginning with April, and production in the first five of these six months has been nearly 13,000,000 tons below this figure. To overcome ths apparent shortage it will be necessary to maintain the average daily rate of production during the seven months remaining in the coal year at 2,037,000 net tons, or 2.9 per cent., in excess of the average daily production in the five months, April to August. In the period beginning with the second week of June to the last week of August, the average daily rate of production has been approximately 2,061,000 net tons, compared with an average daily rate in the period from the first of April to the first of June of 1,864,000 net tons. It is thus evident that only by maintaining production at the level of the last three months through the good weather portion of the coming seven months of the coal year, will the estimated requirements be met. These figures of estimated requirements are based upon 628,000,000 tons for the year, divided between 52 weeks of six working days each, with no allowance for national holidays.

Reports from the carriers for the week of Aug. 31 show increased shipments of bituminous coal from western Pennsylvania, Cumberland-Piedmont and Somerset, Fairmont, Ohio, the district including northeast Kentucky, high-volatile of south West Virginia and smokless fields of West Virginia, the district including Iowa, Texas and Southwest States and from the Rocky Mountain and Pacific Coast States. Material decreases occurred in Tennessee and Kentucky where shipments declined 6.8 per cent. and in Alabama where shipments declined 6.4 per cent. Decreases also occurred in Central Pennsylvania, in Michigan, South West Virginia and the district including Illinois, Indiana and Western Kentucky. Compared with the corresponding week of 1917 all districts show improvement. For the coal year to date all districts with the exception of Michigan report shipments in excess of 1917.

Bituminous coal loaded on vessels at lake ports (including bunker coal) during the week ended Aug. 31, 1918, is estimated at 1,168,583 net tons, an increase over the week preceding of 1.5 per cent. and over the weekly average during July and August of 11.6 per cent.

New England shipments of bituminous coal, during week of Aug. 31, declined approximately 6 per cent. Receipts through the rail gateways declined slightly, while shipments from all harbors, with the exception of Hampton Roads, fell behind the performance during the week of Aug. 24. The current week's shipments, however, both by rail and tidewater, exceeded the weekly average during the coal year to date.

Shipments of bituminous coal from all North Atlantic harbors and Hampton Roads, during the week of Aug. 31, are estimated at 922,545 net tons, approximately 6 per cent. less than the shipments during the week of Aug. 24, but slightly in excess of the weekly average of the coal year to date. Shipments during the week, compared with the week previous, declined from all harbors, New York and Philadelphia falling behind 6 per cent. Baltimore 14 per cent. and Hampton Roads 5 per cent.

Beehive Coke—Production of beehive coke in the United States during the week ended Aug. 31 was estimated at 617,000 net tons as compared with 592,000 net tons during the week of Aug. 24, an increase of slightly over 3 per cent. The daily average during the current week is estimated at 103,000 net tons as against 99,000 during the week preceding. Operators in the Connellsville, Greenburg and Latrobe districts of Pennsylvania report production of beehive coke during the week ended Aug. 31 at 381,977 net tons and an operation of their plants at 75.1 per cent. of full time, as against 74.6 per cent. during the week preceding. Yard labor conditions improved slightly during the week.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended: Aug. 10	Aug. 17	Aug. 24	Aug. 31
Bituminous shipments, 123 roads	217,254	210,431	223,117*	222,814†
Anthracite shipments, 9 roads...	39,280	36,857	40,865	41,281

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

Bradstreet's—Government buying and manufacture on war account make new records, but civilian trade reflects more irregularity, due to a combination of varying crop reports, more acute labor scarcity and increased and still growing difficulty in getting supplies of merchandise and of materials for the manufacture of civilian goods. Over and beyond this, also the new draft legislation, signed at the close of last week, is reported to have had the dual

effect of still further discouraging buying of men's apparel, and in some instances of causing closer scrutiny of credits by wholesalers pending clearer views of the extent to which their customers are likely to be affected by the raising of the draft age.

American Wool and Cotton Reporter—Apportioning of wool on any reasonable basis is likely to be exceedingly difficult. The questionnaire which has been sent out may be intended as a basis for equalizing the supply of raw material which the mills have available; that is, those who have a supply will receive a small apportionment, while those who have no supply will receive a relatively large apportionment. The cotton crop condition of 55.7 per cent. of normal was the feature of the week under review. Some feel that cotton will reach 40c. within a few weeks.

Marshall Field & Co.—In spite of the reductions effected by the price-fixing committee of the War Industries Board in the prices obtained by mills for their product, it becomes increasingly difficult to replace stocks of merchandise at prices prevailing last season either in piece goods or manufactured garments. Mills are looking for a higher basis of price to be announced Oct. 1 and are withholding their product in many cases in anticipation of being allowed a higher level to compensate for the recent rise in the raw cotton market and the increasing difficulty of their labor situation, which is reducing their output to a large extent. Road sales for current delivery were heavier than for the corresponding week in 1917. A few lines are now being offered for spring delivery and the orders indicate that merchants are eager to cover their spring requirements. Current shipments were largely in excess of the same period a year ago. Collections continue good.

The Iron Age—August pig-iron production fell below that of July. It was at a less rate also than the outputs of April, May and June, but was higher than that of any other month since May, 1917. The total was 3,389,585 gross tons, or 109,341 tons a day, against 3,420,988 tons in July, or 110,354 tons a day—a falling off in the daily rate of about 1000 tons. Furnaces in blast Sept. 1 were 372 with capacity estimated at 112,390 tons a day, against 363 furnaces on Aug. 1, with daily capacity of 111,300 tons. Leaders in the industry realize that even the present insufficient rate of production cannot be maintained unless special measures are taken in connection with the new draft. More important still is the maintenance of existing hours and the safeguarding of the industry for the period of the war against such restrictions of output as have commonly accompanied union control. The Lake Superior ore movement in August fell 934,000 tons below that of July, owing to the diversion of vessels from ore to grain.

Atlantic Seaboard

BOSTON

Flow of coal as yet undiminished, although radical reduction is now looked for. Still difficult to unload steamers. Hampton Roads situation causes anxiety and bottoms are in for detention. Byproduct coal again ordered west in heavy volume. Coastwise situation on bituminous is now reversed from what it was last spring. Fuel authorities at work on shutting off coal to plants having on hand more than the permissible stocks. All-rail movement expected therefore to be reduced materially. Expectation that movement to New York piers will be somewhat increased. Awkward situation continues with respect to Washington ruling as to limits for stocks in reserve. Gateways as yet show no falling off in bituminous, but figures will be closely watched the next fortnight. Anthracite screenings tonnage sags. Practically no spot market for the latter. Domestic sizes come forward about on August level. Slight improvement noted in movement of barges.

Bituminous—The second week of September shows no interruption in the flow of coal to New England. Steamers are still arriving from Baltimore and Hampton Roads faster than there is berth room to handle their cargoes promptly. There is congestion at all the railroad berths at Providence, Boston and Portland, and together with a general lack of labor at the wharves the awkward situation reported last week still continues. It is the judgment of the more farsighted in the trade that several of the ships now bringing coal here should be turned into other service temporarily, but naturally there is reluctance on the part of others to take such a responsibility. As far as can be seen now the ships will be needed in another 60 days or so if New England is to be supplied with anything like current requirements. Then, too, the recent taking of three large self-trimming colliers, their tonnage aggregating 17,000 tons, for over-sea service is an indication that the better class boats will be withdrawn from the trade in increasing numbers. The substitutes are slower, take much more time to discharge, and for that reason cannot be figured as a ton for ton replacement.

At Hampton Roads there is real reason for apprehension. At this writing the coal at Newport News and at the Norfolk piers aggregates only 65,000 tons, while there are steamers and other bottoms waiting to the extent of 178,000 tons. In other words, the expected has happened. A considerable volume of steam and byproduct coal has been ordered west and steamers are allowed to bunch at tidewater while someone is busy ordering the coal elsewhere. A lack of coördination is obvious and the trade is beginning to wonder when this will be remedied and New England consumers relieved of paying the bills to the tune of 25c. per ton per day. At Baltimore the outlook is relatively the same. The whole coastwise situation on bituminous is now entirely reversed from what it was last spring. At that time there was a real shortage of boats; today, if it must be said, there is a surplus of boats.

Meanwhile, under directions from Washington, state fuel administrators are working hard to see that coal is distributed equitably. At times, in the congested areas, it is more a question of getting it distributed at all, but the effort is being made to have deliveries withheld from those consumers who have more than seasonable reserves and to see that such coal as comes forward reaches only those whose low reserves justify further receipts. It is all a most difficult situation to administer. Coal pours in from several directions and no system of reporting could be really adequate. Tidewater distribution is easy to control but to divert properly at the gateways is a task beyond any machinery now in operation. It is impossible, under the conditions, to catch even one car in three.

One result of the weekly reports, however, will soon appear in the diminished volume of coal all-rail. So far the September receipts are on a parity with August, the August average having been 725 cars daily, including railway fuel. The District Representatives have now been advised what shipments to curtail and what to increase. The net result will be heavier movement to the New York piers to supply important requirements on Long Island Sound and inland in Connecticut. A better volume to the piers would also enable the Fuel Administration to send coal to ports all the way to Eastport, Maine, which the heavy movement of steamers from Hampton Roads to Boston and Portland has not been able to reach. The next problem will be whether the New York piers will be able to handle all the coal that will be sent in that direction.

Anthracite—The most prominent feature is the extent to which the tonnage of steam sizes has fallen off. The volume of bituminous coming forward has led many consumers to resume their former boiler-room habits, and undeniably the use of screenings has decreased the past month. Today there are practically no requests for barley or silt, and the spot market has all but disappeared. The difficulty of getting these coals forward during the winter has apparently been lost sight of.

As to domestic sizes, the receipts continue about on the August level. The average daily number of cars passing the New England gateways last month was 438, and the first few days of September showed that that level was being maintained.

The improvement in the movement of barges is noticeable, although only slight. The New York piers have thus far shown better results than was expected, although it develops that best results can be had by using both Philadelphia and New York for loading Reading barges. Otherwise the latter would almost certainly fall into delays.

The 30c. advance was effective Sept. 2 on domestic sizes, f.o.b. Philadelphia and New York. It seems to have caused not a ripple of comment, and as yet there have been no increases authorized in retail prices.

NEW YORK

Hard coal situation favorable. Consumers of bituminous well supplied. Little free coal.

Anthracite—In most of its aspects, the anthracite situation continues highly favorable. Production is heavy, and, after all, the fuel problem is more readily solved by a larger output than by the introduction of new methods of distribution and conservation. Official figures show that the high peak of the year was reached in the last week of August, when over 1,800,000 gross tons was shipped out of the hard-coal region. This was the largest weekly output during the present calendar year and was 214,000 tons ahead of the corresponding week of 1917. For the first time this year the average daily production exceeded 300,000 tons for a full week. That this was not due to any abnormal increase in washery output is indicated by the fact that almost precisely two-thirds of the tonnage consisted of domestic sizes, of which pea coal is now counted as one. This is about the average percentage as established by the records of past years.

Of course, the output was kept down last week by the Labor Day interruption, but it is to be noted in this connection that operations were not interfered with to so great an extent as usual, for the number of men who reported for work on Tuesday morning was in striking contrast to the number who, under the old order of things, were accustomed to show up on the day following a holiday.

The same tendency toward keeping the wheels turning with the least possible interruption was observed at this end of the line, for about 25 per cent. of the usual number of cars were dumped over the local piers on Labor Day and about the same number on the preceding Sunday. And with unusual large dumpings for the two or three days following, the week's record was a fairly good one.

The piers in the harbor handled 6713 cars in the week ending Sept. 6 as compared with 7358 cars in the previous week. Locally the hard coal problem has resolved itself, to quite an extent, into the matter of getting more stove and egg coal, particularly stove; of cleaning up the vast number of one- and two-ton orders and of taking care of customers in certain sections of Greater New York where the growth in facilities has not kept pace with recent increase in population. On none of the other domestic or steam sizes is there anything approaching the shortage in stove and egg. Broken coal has been in fairly good supply for some time past and there is no great complaint on the part of most retailers as to the current receipts of chestnut, although the situation varies materially in different parts of the city.

Pea coal is none too plentiful, but a good many consumers who formerly depended on this size have switched to No. 1 buckwheat. The latter size is now in very good supply, although shipments to tidewater are being regulated so as not to crowd the market too hard in view of the fact that its use is now restricted to apartment houses, hotels, office buildings and a few other classes of consumers. The shortage in rice coal has also been overcome except in the case of the highest grades, of which there is seldom enough to meet the demand in full. Barley and No. 4 buckwheat are in oversupply, but railroads have taken steps to see that shipments to the buyers are kept within bounds.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea..... 5.50	6.25		

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—In this immediate section, at least, a great many bituminous consumers are so well supplied that they have little cause for apprehension over the prospects for the near future. The greatest problem in the soft coal trade has to do with meeting increased demands from the steel industry, the Navy and the United States Shipping Board. These requirements involve the use of certain grades of coal, such as West Virginia smokeless and coking coals from western Pennsylvania, which do not figure in the New York market to any great extent.

Of the ordinary steam coals and low grade gas coals there appears to be enough to go around, even though these are being called for in greater volume by industrial consumers whose usual sources of supply are now shipping almost their entire output to the Shipping Board or to the Navy.

The new plan of supervising the storage of soft coal, so as to prevent some consumers piling up huge stocks while others

are unable to make reasonable preparations for the winter, promises to correct the situation which it was designed to relieve. Many consumers,, especially those not on the preference list, have more coal on hand at the present time than they are supposed to have, and in many cases further shipments to such concerns have been ordered discontinued. This has naturally made it easier for other consumers not so well stocked to round out their storage piles, so that by the middle of next month, when transportation troubles may be expected, there will probably be few concerns not reasonably well protected against any temporary interruption to deliveries.

For the last two or three weeks there has been a slight falling off in tidewater shipments of bituminous to New York harbor, which may be accounted for by the diversion of some coal to Baltimore and Philadelphia for transshipment by water to New England. The local piers handled about 1000 cars less of soft coal in August than in July.

In the week ending Sept. 6 the dumpings aggregated 6662 cars as against 6844 cars the week before. The difference is not marked, owing to the fact that operations were carried on at some of the loading ports on Labor Day and on Sunday of last week.

The up-turn in bituminous output recently recorded for the country as a whole, and the announcement that the central Pennsylvania mines turned out a record week's tonnage late in August, seem to confirm the belief that the midsummer decline in production was due to weather conditions interfering with the prompt discharge of cars at points of destination, rather than for any change for the worse on the railroads or as regards labor at the mines.

From the jobber's standpoint things have not changed much, except that tonnage contracted for comes along in better volume as output increases. There is still little coal to be picked up in the open market, the bulk of the shipments continuing to move through regular channels under arrangements entered into months ago.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3 08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite settles down to busy routine. Consumers still anxious. Dealers experience trouble with labor. Local shipments better. Steam coals well taken, with an occasional tendency to weakness. Bituminous car distribution better. Local receipts fair. New distribution plan in effect.

Anthracite—All dealers have plenty of orders on hand and small stocks, and while the coal arrives somewhat slowly yet there seems to be an increasing steadiness and we hear little these days of teams standing idle, as was the case at times during July and August. The consumers, of course, are still anxious to have deliveries made and are keeping after their dealers with little let-up.

The dealers are anxious, naturally, to accumulate some coal in their bins, as ordinarily at this time of year their yards are quite full as contrasted with the present empty state. As a result they continue to harass the shippers, to whom they are prone to exaggerate their troubles. After a careful survey of the situation, and accepting the judgment of those high in the trade, we are more confident than ever that the severe trials of last winter will not be repeated. We are also of the opinion that labor shortage with the retailers will be the cause of more trouble than coal shortage. Dealers who have tried to speed up their deliveries by offering bonuses to their drivers for every ton over a certain number delivered each day, are not so sure that it is a wise policy. It proved satisfactory when the stock of coal on hand warranted overtime and extra effort to deliver. When the stocks dwindled and the same opportunities to make extra pay did not exist, then the yard help became dissatisfied and immediately asked to have their wages raised and this feeling still prevails.

The new price effective the first of the month caused practically no comment. The shippers did not announce the advance by circular and some dealers for a few days actually lost sight of the fact that coal was costing them more.

This week the anthracite distribution committee announced that they had accomplished their plan of giving a heavy advance tonnage to the New England territory and had actually exceeded the tonnage that they had hoped to place there during the summer. While good shipments are understood to be continued in that direction it is the general opinion that from now on this territory will begin to get every week a greater percentage of coal.

The retail men were again called upon the other day to furnish further details of their business to the local administrator, Mr. Lewis persists in being kept informed as to the number of tons of coal ordered, undelivered, in stock, and in transit to every yard in the city. The information is always forthcoming, but the trade with the short help does tire of the detail work involved.

The anthracite committee of the United States Fuel Administration is now sending to the producers and distributors the allotments by cities in the various states. There has been no particular interest aroused here as yet because they have not heard of the required tonnage to Pennsylvania: neither has New York or New Jersey been covered at this writing.

Broken continues to be consigned to the gas companies, public utilities and brass foundries, with little or none for domestic use. In order to see that these industries received the necessary amount of this size the authorities have recently apportioned the tonnage to the different shippers, as this is a size that must be made to order. Egg coal is comparatively free in the city proper and many of the smaller dealers have filled all their orders for it. In the outskirts, where the houses are larger and where most of the city's requirements for that size is consumed, the dealers continue to plead for it. Stove is by all odds in the shortest supply and by far the largest percentage of unfilled business calls for this size. The dealers claim it is still too early to persuade their trade to accept another size as a substitute. Chestnut is the next in proportionate demand, while pea coal is the easiest of the four popular family coals. The first cold snap is likely to change conditions and cause a quick demand for pea coal from the small buyer for small houses. Ordinarily all dealers were anxious for a large stock of pea with which to start the fall season.

Several shippers report a weakening in the steam sizes, noticeably on barley and culm. It is also true that fewer inquiries are coming in not only for these two sizes but on No. 1 buckwheat as well. The increased production of the washeries and dirt banks is having its effect there. Of course the cutting off of No. 1 buckwheat and the changing to bituminous by certain manufacturers is noticeable, especially as none of these sizes are yet in use for domestic heating purposes. There are some who predict that No. 1 buckwheat will be fairly easy before the end of the month, a condition, however, that is not likely to exist far into the season.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—There has been a noticeable change for the better in bituminous lately. In fact during the last ten days the car supply has been running close to 70 per cent. of the present capacity of the mines. Many shippers, however, report labor conditions more acute than ever, as the men have a tendency to float around from one mine to another with the varying car supply.

With the entire production in the hands of the distribution committee these men are making the most of the production at hand. They have now arranged that all war industries shall have a 30-day supply, while those on non-war work have been put on a 15-day basis. As a consequence of this there is quite an accumulation of stocks all around this territory. While the local market in this way is being fairly well taken care of, it is understood that extra efforts are being made to take care of out-of-the-way places in New England. With the changed aspect in distribution many of the very largest plants who succeeded in getting from a 60- to 90-day supply are somewhat held back and they are skirmishing around to find means to continue the rate of stocking which they have enjoyed all summer. One plan is to send representatives into the region, which has been done to an increasing extent of late.

BALTIMORE

Bituminous situation continues fairly easy, but about one-third of the local tonnage continues to come in box-cars. Much coal of unsatisfactory grade. Hard coal men still lack tonnage. Apportionment for Maryland points announced.

Bituminous—Handlers of bituminous and officials connected with the local fuel administration report a fair tonnage now moving here. More than 1000 tons a day average for local use is now coming through. The heavy movement of coal in box-cars, which means both a greater initial cost and an extra cost for unloading, is an element of concern to consumers. This is the more pronounced as a considerable part of the coal coming in box-cars, as well as some of the fuel reaching here in open-top cars, is of most unsatisfactory grade. Baltimore has been particularly hard hit in the matter of good coal supply for industries outside of the war-industry and Government class, because of the fact that of the fuel left in this zone the Government has taken practically all the highest grade for its own use and has eaten heavily even into secondary coals. A considerable part of the coal reaching here outside of the tidewater pool on outside the capes movement is to the account of the Maryland Fuel Administrator and is being distributed by him to the most needy consumers through the purchasing agents, who file claims for coal.

Anthracite—Hard coal dealers here still lack the tonnage now being urgently demanded by consumers, many of whom have had orders in since April and May and have not as yet received even part of their expected tonnage. The fuel administrator is now compiling the August figures of tonnage received and distributed, and of orders still unfilled. At the outset of August there remained 322,725 tons of unfilled orders on the books of dealers. For April, May, June and July there was a total of 232,218 tons received here. The entire city allotment was definitely announced this week as 713,318 tons. This means that less than one-third of the city allotment was received here in the first four months of the coal year. As the allotment was fully 10 per cent. under the estimates of extra coal needed to meet war-industry demand and shortage in yards here at the outset of spring, it can be seen that the situation is far from assuring. The allotment announced for other Maryland points was as follows: Arlington, 17,244 tons; Annapolis, 15,000; Hagerstown, 14,585; Frederick, 11,601; Walbrook, 9671; Notre Dame, 7958; Chevy Chase, 6807; Cambridge, 6378; Catonsville, 6849; Bethesda, 6198; Easton, 6014; Havre-de-Grace, 6000; Towson, 5997; Chestertown, 5601; and Salisbury, 4936 tons.

Lake Markets

PITTSBURGH

Important cases of stocking coal discovered. Lake shipments behind. More allocations.

Investigations indicate that there has been more stocking of coal by consumers than was generally realized, but the stocking has not been uniform by any means, some consumers having nothing at all. The official ban upon stocking Pittsburgh district coal until after lake shipments are ended is as rigid as ever, and would be more rigid if the authorities had means for making it so. Production has increased slightly, except for the backset given by Labor Day, which was rather generally celebrated. The miners did not celebrate the day after as much as formerly, however. Lake shipments are decidedly behind schedule and are not picking up. The situation will probably make it necessary to continue shipments beyond Oct. 15, by which time it had been hoped the movement would be concluded. The period in which line consumers can stock up for the winter will be correspondingly reduced.

Allocations of coal are more frequent, and shipments are cut off now and then to consumers not recognized as essential, or who have stocks upon which they can draw readily. Brokers are doing scarcely anything. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to be charged consumers by regular brokers.

TORONTO

Dealers overtaking delayed deliveries. Price of anthracite advanced. Possibility of curtailed allotments for Canada. Plenty of soft coal, but consumers must do delivery.

Coal is coming forward fairly well, and dealers are gradually overtaking orders in arrears. New orders are generally refused. The price of anthracite has been advanced 50c. per ton by most dealers owing to increased cost at the mines and additional freight charges, though some are filling orders on hand at the former price. The possibility of curtailed allotment for Canada is causing some anxiety, as it is feared that there may be a diversion of anthracite shipments to supply the New England States. The city authorities are considering the issue of an order stopping deliveries of hard coal to those consumers already partly supplied until those having none are supplied. Soft coal is readily obtainable by those who can provide for its delivery.

Quotations for best grades per short ton are as follows: Retail anthracite, egg, stove, nut and grate, $11 to $11.50; pea, $10 to $10.50; bituminous steam, $9.25; slack, $8.25; domestic lump, $10.50; cannel, $13, wholesale f. o. b. cars at destination, three quarter lump $7; slack, $5.82.

BUFFALO

Bituminous rather quiet. Canadian trade not active. Supply not coming this way heavily. Anthracite local prices higher. Lake shipments fair.

Bituminous—Jobbers are finding it about as hard as ever to get a supply, especially since so much of the Pittsburgh coal has to go to the lakes. When that movement drops off this district ought to be better supplied. It is always that way in early fall, but when there is a real surplus the consumers are willing to wait. The fuel administration is now cutting off the local consumers who have a large amount stored up, but promising more when the supply runs down.

Bituminous prices have not been changed lately, being $4.65 for thin-vein Allegheny Valley, all sizes, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine run and slack, $5.65 for smithing and smokeless, and $6.10 for cannel, all per net ton, f.o.b. Buffalo. Most shippers prefer to sell at mine prices.

Anthracite—The demand is quite as active as formerly, but the supply does not increase, so the local distribution has fallen considerably below the former average. The fuel authorities say that the amount allotted to the city and county is sufficient and that the plan is to keep long-distance shipments up more closely than such as can be made with little additional expense in cold weather. An advance of local prices was made on the first of the month, the amount being 30 cents a ton on all sizes but grate and buckwheat, which are unchanged. The wholesale price to retailers is $7 for grate, $6.90 for egg, $7.20 for stove and chestnut, $5.75 for pea and $5.75 for buckwheat. The retail price to the curb is $1.85 more, with 50 cents additional to the man who houses it.

The shipments by lake appear to have been cut down by the holiday, being for the week 91,044 net tons, of which 44,100 tons cleared for Duluth-Superior, 14,344 tons for Milwaukee, 9600 tons for Sheboygan, 8600 tons for Marquette, 7700 tons for Fort William, 3200 tons for Green Bay and 3200 tons for Hancock.

CLEVELAND

Hopes that the closing of the lake season would make additional supplies of bituminous available in this district have been shattered by the semi-confidential information that the urgent coal demands of the Allies will compel the diversion of large tonnages to Buffalo and Pittsburgh. Ohio mines, however, are to be relieved of practically all of their railroad fuel, coal to come east from Illinois and Indiana for that purpose. Lake shipments in August set a new high record, but with Labor Day, labor seems to have ended its spurt and has proved more unsteady than at any time so far this season.

Bituminous—According to semi-confidential reports in circulation among operators here the Allies, particularly Italy, have made unprecedented demands upon the United States for coal. As a result, so the report has it, the lake season may arbitrarily be ended Nov. 15, or a large tonnage that ordinarily would proceed to the Northwest in late November and early December be held in the lower lake regions to supply domestic and industrial consumers. The lake season at an end, Ohio coal is to move east to Buffalo and Pittsburgh, and western Pennsylvania coal forwarded to tidewater. In order to make this movement as large as possible it is said that Ohio mines are to be relieved of the necessity of providing any railroad fuel at all, and already some operators are said to have received notice to forward their railroad fuel to the lakes, in anticipation of an eastward movement from Illinois and Indiana mines. This turn of affairs has not made operators feel any more optimistic concerning an adequate local supply this winter. Railroad fuel is quite an item with Ohio operators, since every New York-Chicago line crosses the state. The labor situation at mines in the No. 8 district of southern Ohio this week has been the worst of the season, due to the Labor Day hangover. At one mine employing a few over 500 men 91 were absent the day following the holiday. The reduced production, however, is said to be less than would seem probable, inasmuch as car supply has gone back to its steady gait. No industrials are getting any bituminous until operators are satisfied that their stocks do not exceed the Fuel Administration's maximum limits. Retail dealers are not getting one quarter, if that much, of the tonnage they could dispose of. The detailed report of the Pittsburgh Vein Operators' Association of Ohio on the car supply in August shows the average shortage for the month to have been 21.98 per cent. The best car supply was on Aug. 5, when it was only 8.18 per cent. short, and the worst on Aug. 21, when the shortage was 39.24 per cent.

Lake Trade—The Ore and Coal Exchange, Cleveland, which is conducting the pool of Great Lakes tonnage this year, reports that in August the lake fleet loaded 4,805,049 tons of bituminous, exclusive of bunker fuel. This is a record. In September, 1917, the fleet loaded 4,699,000 tons, the record up to August's performance. Since August was a 4,900,000-ton month on the Federal Fuel Administration's schedule, the season up to Sept. 1 is approximately 1,089,000 tons behind. Receipts at lower lake docks this week have been remarkably good, despite the Labor Day cessation at the mines and the attendant difficulty in getting back to the schedule. Tonnage is available plentifully so far this week, though in the latter part of last week the congestion at the ore docks held considerable back.

DETROIT

Shortage of domestic coal continues a harassing factor of Detroit trade. Anthracite supply is not improved. Lake trade is stronger.

Bituminous—Domestic coal users in Detroit received a sharp reminder of unfilled coal bins this week with a sudden drop in temperature and cold rain. Despite a slight increase in the proportion of domestic sizes coming into Detroit, the bituminous received is still chiefly mine-run stock, which is not suitable for satisfactory consumption in hot air furnaces and baseburners. Domestic lump and prepared sizes are not so plentiful as should be the case to provide for requirements of the many homes which will be unable to obtain anthracite.

In the effort to increase the supply for domestic use, manufacturing plants are instructed to obtain their coal supply from Illinois and Indiana mines. Quite a number of steam coal users, some of whom have had unsatisfactory experience with coal from those fields, are objecting to the substitution of what they regard as inferior stock for the West Virginia coal they have been accustomed to receive. Some have expressed a willingness, it is said, to close their plants rather than use coal which they assert would injure their furnaces.

Anthracite—Householders who are dependent on baseburners and who have been unable to place orders with retailers are making application to the fuel administration this week, through a clerical force in the Board of Commerce. Each home is permitted to order 3 tons, and the opportunity for placing orders will be terminated on Sept. 10. More than 5000 applications were received the first two days. Owners of hot air furnaces are to get no anthracite until those using baseburners are supplied. Meantime the movement of anthracite into Detroit is extremely light.

Lake Trade—Coal is moving over the lake routes in better volume than heretofore. August shipments were 4,805,049 tons, just under the mark of 4,900,000 tons set by the fuel administration for the month.

COLUMBUS

Special efforts still being made to supply the Northwest with fuel. As a result limited quantities are apportioned to the domestic and steam trade.

The Federal Fuel Administration is making every effort to supply the upper lake region with fuel before the close of navigation. Coupled with this movement is a demand from Michigan which is taking much of the available tonnage. Some coal is apportioned to the domestic and steam trades, but there is a shortage, especially in the former. Generally speaking, the tone of the trade is good.

Lake trade is moving along smoothly as far as vessel transportation is concerned. But shortage of cars and lack of motor power are reducing the output in practically every producing field of the state. Consequently some concern is expressed over the fuel situation in the Northwest. The movement of tonnage from the docks to interior points in the upper lake region is good and there is no congestion as in former years. Lake prices are still firm at Government levels.

Domestic trade is active, although limited receipts are holding up deliveries to householders. Retailers who had surplus stocks are in a position to take care of their retail trade. Some coal is arriving from mines which do not have lake shipping licenses. Pocahontas is now entirely out of the Columbus market and there is little anthracite to be had. The bulk of retail coal is supplied from Hocking Valley and West Virginia. Retail prices are firm at former levels, which takes into account the recent reduction of 5c. in most Ohio districts. A survey of the state shows that a larger amount of domestic coal has been stored than in any previous year.

Steam business is strong and the demand is firm. There is a considerable amount of screenings finding its way into the local trade, as many mines in the Hocking Valley are shipping prepared sizes to the lakes. The recent ruling curtailing storage of steam plants has produced a wider distribution of the available tonnage. Schools and public institutions are now fairly well supplied.

CINCINNATI

Increasing anxiety on the part of manufacturers to secure fuel features the market, but contracts depend upon Government's view as to whether operation is essential. Deliveries are good.

The coming of the first fall month has brought home to numerous manufacturers the fact that winter is just ahead, and their anxiety to secure an assurance of an adequate fuel supply, as well as for regular power consumption, is keener than ever. There has at no time been any cessation in the inquiry for industrial fuel, but of late this has assumed a more insistent note, due to the development in a number of cases that the Government was still to be shown that the industry in question was to be considered as essential. Several delegations of business men have gone to Washington to attend a series of conferences on this matter, and they hope to be able to secure definite classification of their several industries as essential, with orders to the Fuel Administration to give them listing that will entitle them to a regular supply of fuel. It has become self-evident that many manufacturing concerns will have to go on short fuel rations or none at all, and it follows that the available coal will go to those rated as indispensable. The volume of fuel going forward is large, but figures below the amount required to meet all demands. The Labor Day holiday, while in some instances dispensed with or only partly observed, none the less cut into production as usual, and while the following day's let-up was not expected to be as bad as formerly, on account of the prohibition laws prevailing, especially in West Virginia, the loss is felt. Domestic consumers are already well taken care of, although dealers are still after coal for current delivery.

LOUISVILLE

Better supplies of eastern Kentucky received. Stocking demand good on this grade. Western Kentucky stocking slowing down for present. Cold weather expected to bring late rush. Steam demand fair.

A better movement of coal has been experienced from the eastern Kentucky field during the past few days, although most of this coal is straight mine-run, the producers not screening under the present heavy demand from the lake region. Mine-run is taking care of the steam consumption, but is not producing the much needed lump for domestic stocking. Retail demand for eastern Kentucky lump is heavy, with dealers holding considerable orders for such coal provided they receive it and can make delivery.

At the present time domestic stocking on western Kentucky grades has slumped somewhat, and the dealers are well up on deliveries and managing to take care of

all inquiries. Production in both fields is fair considering the labor situation. Cars are in better supply than they have been for some time past, and shipments as a whole are standing up well.

Jobbers have been handling as much western Kentucky coal as they needed, but have been having trouble in securing eastern Kentucky grades, and some of the producers have been buying up the output of small mines to take care of their demand. Some of the jobbers have been handling small supplies of Indiana coal during the past few days.

BIRMINGHAM

Pressure for steam coal has eased off some, though the demand is still greater than the supply. Domestic trade strong, dealers having many unfilled orders on file. Production for past week will approximate 430,000 net tons in Alabama. Slackers continue to throttle the output.

Reports in trade circles indicate a little slackening of the pressure for steam coal, though ample business is offered and in hand to more than absorb the production. Otherwise there is no change of a material nature in local market conditions. There is no indication of any let-up in the demand for domestic coal, each succeeding month from Apr. 1 showing a substantial gain in coal deliveries by dealers over the preceding month. Receipts are inadequate to meet the abnormal demand at this season, and the yards are kept cleaned up.

Production at the mines in Jefferson County on Labor Day was fairly good. Reports from the Cahaba field indicate about a half normal output, while many mines in Walker County were idle the entire day, no men reporting for duty. Mines on the Southern Ry. suffered some from an inadequate car supply at times during the past week. Operations on other lines were not materially affected by car shortage.

Coke

CONNELLSVILLE

Operators trying to make better coke. In three months beehive coke production decreases much more than byproduct increases.

Efforts are being made to bring about steadier operation of coke ovens and more careful selection of coke, so that the poor coke some furnaces have been complaining of will be eliminated.

Production of pig iron in August was at a rate about 1 per cent. lower than the July rate, but this is attributed to high humidity of the atmosphere rather than coke conditions. Shortages of coke and cases of poor quality have been fairly regular, not distinguishing one month from another particularly. On the whole, however, coke supplies lately have not been altogether so good as three or four months ago. This fact is receiving the careful attention of the Fuel Administration and representations were made to the Railroad Administration some time ago.

The best coke production of the year, taking the country as a whole, fell in the four weeks ended May 18, when production averaged per week 683,000 tons of beehive and 481,000 tons of byproduct, making a total of 1,164,000 tons. In the four weeks ended Aug. 24 production averaged 589,000 tons of beehive and 535,000 tons of byproduct, a total of 1,124,000 tons. Thus there was a decrease in the total of 40,000 tons a week.

A more startling fact is that the production of beehive coke actually decreased by 94,000 tons, and the decrease of only 40,000 tons in the total was caused by the byproduct output increasing 54,000 tons. As new byproduct ovens were being completed in the past few months fears were entertained that they might draw so much coal from beehive fields as to decrease the output of beehive coke, but the development has been very much worse than that. The Connellsville region has practically a clear record in this matter, however, as while its beehive coke output may have decreased a trifle, it has been shipping much more raw coal than formerly.

The market is without incident, furnace coke being allocated before there is opportunity to offer it in the open market. Foundry coke continues to be offered rather freely, giving foundries an opportunity to stock. Set prices control furnace and foundry coke, at $6 and $7 respectively, crushed, over 3-in., being limited to $7.30. Carefully prepared material from old dumps, over 3 in., is bringing $6.75 for the best grades, for distribution to domestic consumers.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Aug. 31 at 338,250 tons, an increase of 545 tons over the week previous.

Buffalo—The situation is not materially changed. All furnaces in this territory are active, but they are so dependent on a scant supply of coke that their operations are in a sense curtailed by it. The byproduct ovens here are run at full capacity and they supply most of the needs of the district, so that the beehive districts are drawn on only in a moderate way. All breeze coke placed on the market is eagerly taken by jobbers, who as a rule sell it to regular customers at a moderate price. The iron-ore movement by lake continues heavy, receipts for the week being 337,400 gross tons.

Middle Western

MILWAUKEE

Hocking coal advanced in price to meet increased freight rates. Lake receipts of bituminous coal heavy. Conservation measures advanced.

Milwaukee coal dealers have been directed to advance Hocking coal 38c. per ton, beginning with Sept. 1, because of increased freight rates. Screened Hocking now sells at $7.93; pile run at $6.93 and lump at $6.68. A charge of 50c per ton is added when coal is carried in to bins. There have been no changes in prices of other grades of coal.

The month of August went over the top in regard to receipts of bituminous coal, and beat the record of any previous month. Cargo receipts of coal since May 1, when the docks were practically bare, were as follows:

	Anthracite Tons	Bituminous Tons
May	85,700	389,547
June	53,947	434,094
July	106,037	554,711
August	119,293	768,060
Total	364,977	2,146,412

September's record, including the first four days, foots up 3300 tons of hard and 82,656 tons of soft coal.

State Fuel Administrator Fitzgerald says Milwaukee is in no danger of a shortage of coal if proper economy is practiced. Householders are being instructed in furnace firing and an expert is supervising the conduct of power plants. The intent is to grant more coal to plants which are efficiently managed than to those where carelessness prevails. Essential war industries will be provided with a ninety day supply of coal. Nonessentials will have to take their chances with the fuel administrator.

The lightless order has been extended from two nights per week to four, beginning with the first week in September. Milwaukee country clubs will have to close their houses the coming winter, as they will not be allowed coal for heating after Dec. 1, and it is possible that surplus stocks in bins at these resorts will be taken over by the fuel administrator. Wood will be permitted, however, if it is not received by rail. At present summer cottagers on Wisconsin lakes are denied the use of anthracite for cooking purposes. Wood or soft coal only are permitted.

Some coal dealers find it difficult to compete for business in the present state of hide-bound regulation and have resorted to the practice of mixing poor coal with a better grade. The fuel administration office has given notice that any dealer found guilty of this kind of fraud will be denied the right to purchase coal.

ST. LOUIS

A quiet and slow market, with no demand from any source. No domestic business developing. Cars continue short on some roads and transportation shows slight improvement. Steam business quiet and a surplus of coal is on the market.

The situation is extremely easy in St. Louis. There is no demand for domestic coal other than that for Carterville, of which the supply still continues short. Steam business is unusually quiet. The steam plants do not seem to feel that they should store much coal ahead, and they are not storing any. Even the large public utility plants are not storing coal to the extent that the Fuel Administration desires, and up to the present the Terminal R. R. has no storage coal on the west side of the river. The Terminal was the cause of much trouble last winter, as it confiscated coal going to dealers and essential plants on account of its failure to store a sufficient supply, and it is not profiting by last winter's experience.

Business from the country is extremely quiet. There is a little domestic coal moving, but not in the volume that might be expected. In the Williamson and Franklin County field car shortage still continues somewhat severe, but transportation has proved better in the past week. Labor shortage is the cause of many mines making a poor showing.

A large tonnage of this coal still continues to go for railroad purposes and a small portion goes to the St. Louis market. In some sections in Missouri steam plants are using this coal that should use Standard or Mt. Olive, but lack of regulation permits this, and the same is true generally of steam plants in Illinois and Arkansas. Somewhat similar conditions obtain in the Duquoin field.

The Standard mines to a great extent have a surplus of steam sizes and in the past week No. 2 nut became heavy.

For two or three days there has been plenty of 2-in. lump coal. As a matter of fact, there has been more than the market could absorb, while 6-in. lump and 3 x 6 egg are in good demand at the Government maximum. Two-inch lump went down to $2.40, screenings are around $1.50, and mine-run is from $2.15 to $2.25. Car supply in a general way is somewhat better and transportation shows improvement.

The Standard field situation looks better. The railroad tonnage is good, and were it not for this the Standard mines would be idle on account of having no place to market their product. There are no eastern coals coming in and a light tonnage of Arkansas.

The prevailing market price per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....
No. 3 nut	2.55@2.70	2.55@2.70	.....
No. 4 nut	2.55@2.70	2.55@2.70	.....
No. 5 nut	2.05@2.20	2.05@2.20	.....
2-in. scrgs	2.05@2.20	2.05@2.20	1.25@1.50
3-in. lump	.....	.....	2.25@2.40
2-in. lump	.....	.....	2.25@2.40
Steam egg	.....	.....	2.25@2.40
Mine run	2.35@2.50	2.35@2.50	1.85@2.00
Washed:			
No. 1	2.75@2.90	2.75@2.90	.....
No. 2	2.75@2.90	2.75@2.90	.....
No. 3	2.55@2.75	2.55@2.75	.....
No. 4	2.55@2.75	2.55@2.75	.....
No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

General Statistics

ANTHRACITE OUTPUT FOR FOUR MONTHS

Figures showing the distribution of anthracite during the four months Apr. 1 to July 31 reveal that each of the New England States received tonnage in excess of its allotment, while the Middle Atlantic States, with the exception of Virginia, ran behind. In all cases, however, the departure from schedule, based on the 1916 distribution, was relatively slight and was accounted for in the main by the carrying out of the Fuel Administration's policy of favoring far-away sections in the early part of the coal year and making up the deficit in nearby states by heavier shipments later on.

Details are shown in the following tabulation:

State	Due on Allotment Apr. 1-July 31 Tons	Distribution Made Apr. 1-July 31 Tons
Maine	220,000	244,363
New Hampshire	125,000	141,022
Vermont	110,000	135,642
Massachusetts	1,896,332	2,102,466
Rhode Island	266,768	268,778
Connecticut	825,568	914,235
	3,443,668	3,806,506
New York	5,285,100	5,046,306
New Jersey	1,820,260	1,746,141
Pennsylvania	2,686,568	2,635,827
Delaware	81,952	74,450
Maryland	342,440	341,368
District of Columbia	221,932	219,429
Virginia	34,132	54,776
	10,472,384	10,118,297
Nine Central and Northwestern States	2,002,313	1,780,681
Canada	1,200,668	1,251,942

COAL AGE

Volume 14 New York, September 19, 1918 *Number* 12

John and the Ton of Rock

ON a certain payday in March John James paid $36.50 to a representative of "The Fatherless Children of France, Branch of the American Society for Relief of French War Orphans." This amount, he had been told, would keep a fatherless French child one year. In due time John received a letter from France, which his French neighbor translated as follows:

Dear American:

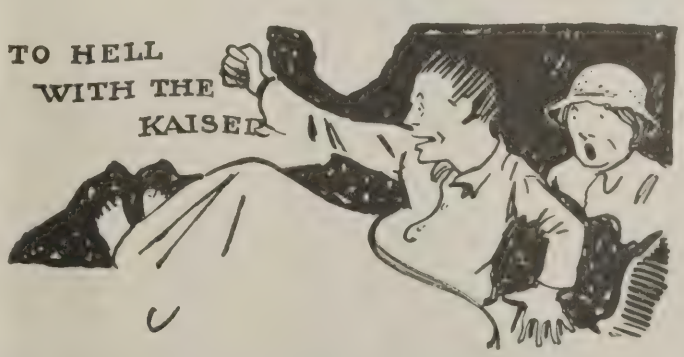
My mother and I salute you. My father was killed in battle. They say he had to make a defense on one of the days when there was not enough ammunition, so he did not have a chance, but he was very brave. My mother works every day as a laborer, as there are not enough men now to do the work that must be done. She is not strong, so has a hard time of it; but she says the Americans are so patriotic and will change all of these things soon. I will pray that you may help us and that we may thank you as we should.

MARIE.

That night John had a dream.

During the day he had loaded something like 300 pounds of rock into every car of coal that he sent to the top. Since the demand for coal had become so acute dockage rules were like scraps of paper and there were few who paid much attention to them. Seven cars of coal John loaded that day, and the rock in these cars amounted to about one ton.

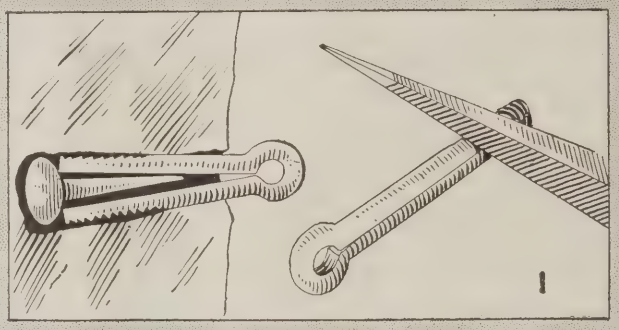
In the dream it was **exactly** one ton of rock, and floating above it was a large banner calling attention to the fact that here was a ton of rock. On the other side of the banner was the legend, "Hoch the Kaiser, whom we serve." As John looked at the banner, first one side was visible and then the other—the reference to rock on one side, the legend about the Kaiser on the other.



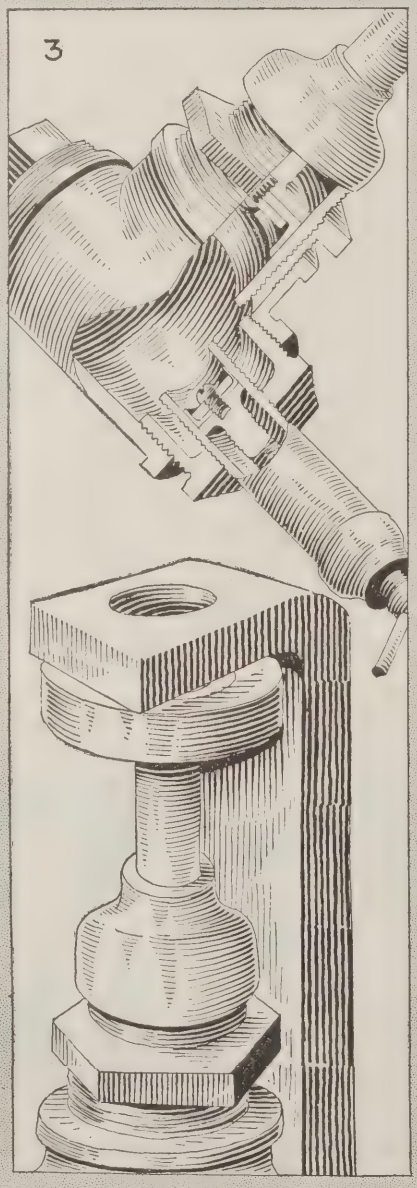
That Kaiser stuff didn't appeal to John, even in a dream. He made a lunge at the banner, but the mass of rock blocked him.

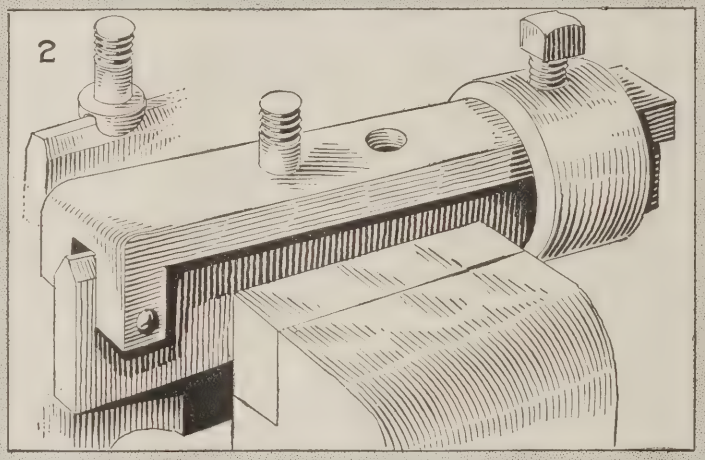
"You put me here," said the ton of rock. "I was in your power then, now I'm out of your power. Half of me will get into a railroad locomotive tomorrow, and because of me the fireman will lose his steam; his train will be delayed three hours. Think what that means to friend Kaiser, with freight congested as it is now and not enough men to handle it. All of your women will soon be at work. The other half of me will be sent to a coke oven to be turned into blast-furnace coke. My, but that blast furnace will cut up when that coke gets dumped into it! Furnaces can't melt iron with rock. Maybe friend Kaiser won't like that, also; the iron from that furnace goes to a steel works and then into ammunition."

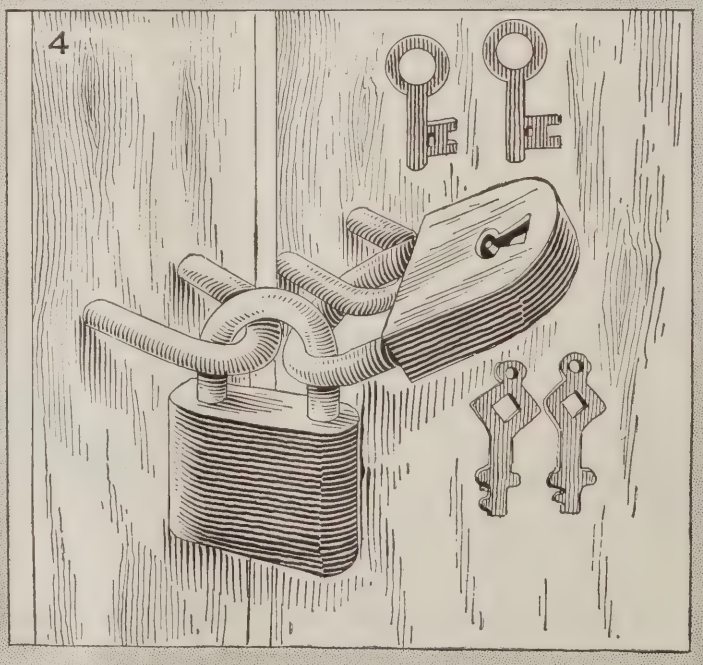
With that the pile of rock seemed to melt away, and in its place stood only the banner; but the wording on the banner had changed. Now it ran: "You Americans are so patriotic."



Just then John frightened his sleeping wife almost out of her senses by springing up in bed, yelling frantically, "To Hell with the Kaiser and all who serve him."

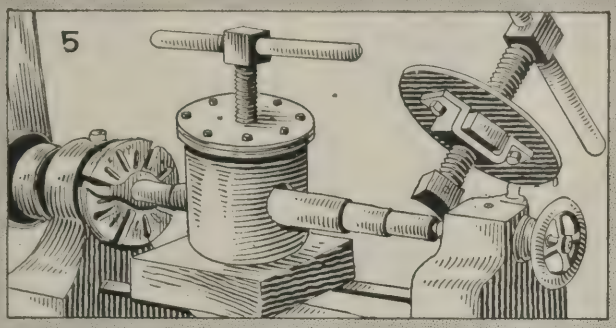


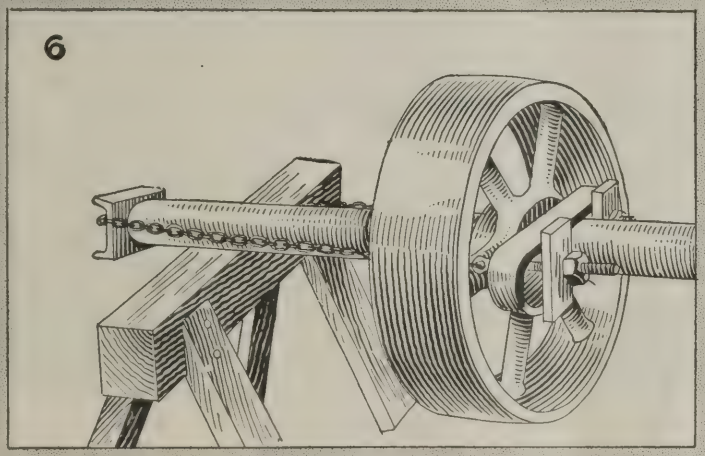


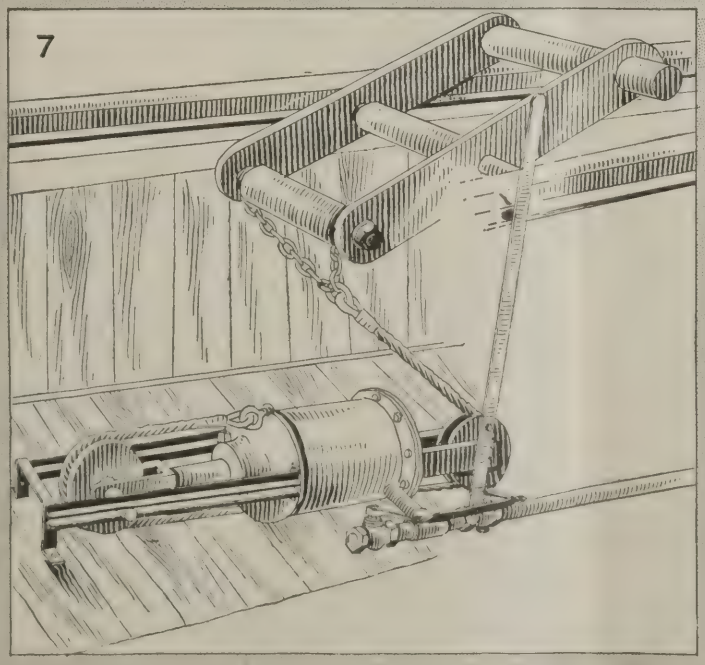


IDEAS AND SUGGESTIONS

1. Cotter pin and nail make fine expansion bolt.
2. Holds machine screws tight without marring.
3. Small hydraulic press.
4. Four men have access to locker by this arrangement.







KINKS FOR USE AROUND THE MINE

5. Axle straightening device.
6. Simplifies removal of pulley.
7. Car hoist made of pipe fittings.
8. The cylinder and piston.

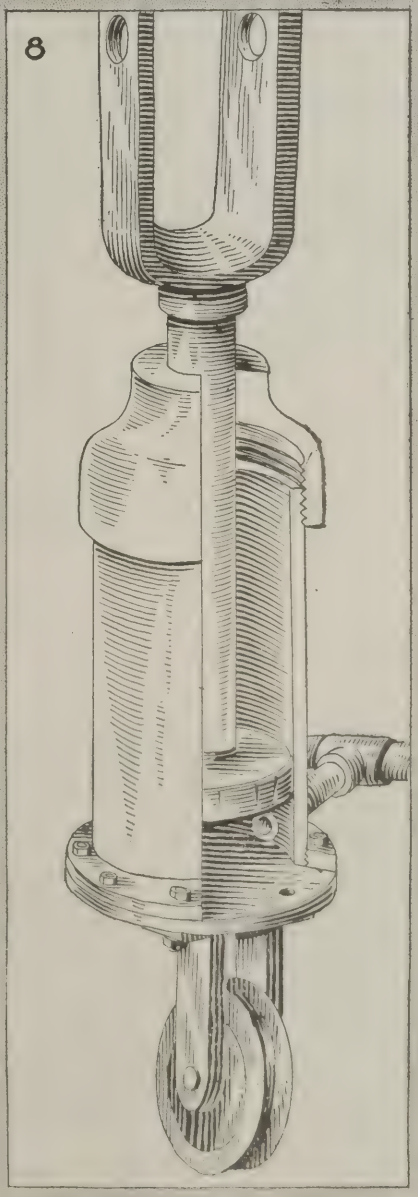


FIG. 1. UNION MINE OF THE LA SALLE COUNTY CARBON COAL CO. IN ILLINOIS

Machine Mining at La Salle, Illinois

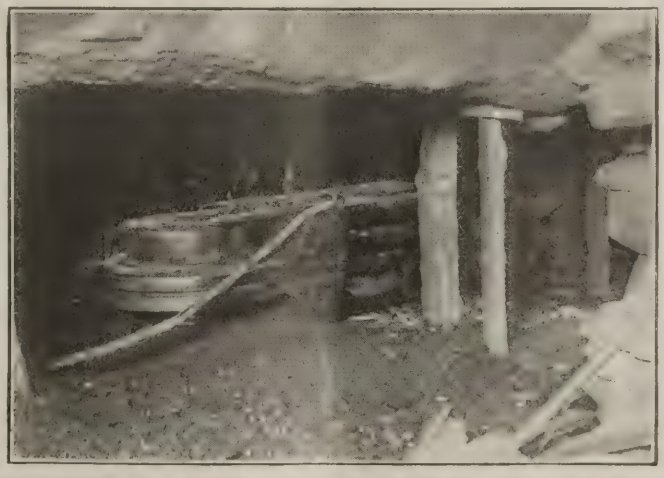
By GEORGE W. HARRIS
Editorial Staff "Coal Age"

INDIVIDUAL preference in mining should not be challenged any more than a person's choice of political parties or any other matter about which people differ. Some men prefer to work in a three or four-foot seam, longwall mine rather than in an eight to ten-foot room-and-pillar mine. They become accustomed to the longwall top doing the hard work of breaking down the coal for them and appreciate the good, clear air always sweeping along the working face. Many times longwall men leave their jobs only to return to them again in a short time. If the arduous task of undercutting the coal is done by machinery, then the work of mining is largely reduced to loading the coal into cars, taking care of the top at the face and building pack walls on the part of the longwall miner, or "loader," as he then is called.

One of the best-known longwall regions in the country is in the northern part of Illinois, and here this method of mining reaches its greatest development in Bureau and La Salle counties. It is of historical interest to note in this connection that the first mention of coal in the country which afterward became the United States was in the Illinois River territory. At the end of June, 1917, there were only 14 longwall commercial shipping mines in the first inspection district of Illinois, and their tonnage was only about 2⅓ per cent. of the total produced by the state.

Nevertheless, there are some important mines in this section, and among these are the four plants of the La Salle County Carbon Coal Co. These four plants produced over half a million tons of coal in the year ended June 30, 1917, out of a county production of 885,774 tons. The La Salle company uses Sullivan "Ironclad" longwall mining machines at two of its plants—those which have reached the greatest development. A description of the La Salle plant of this company, together with notes about longwall mining, appeared in the Aug. 8 issue of *Coal Age*.

An illustration showing the Union plant of the La Salle County Carbon Coal Co. is given in Fig. 1. This mine was opened in 1874 and is in Peru, at the west end of the town of La Salle. The newer construction at this



plant is plainly evident in the masonry engine house, the boiler-house stacks and the steel concrete fan. The wooden tipple is probably a survival of the day of timber structures. One of the latest plants of this company, its No. 5 mine, has a fine steel tipple.

At the Union, as well as the La Salle mine, undercutting is done by Sullivan longwall machines, which are shown at work in the mine in Figs. 2, 3 and 4. The seam here averages about 40 in. in height and the undercut is made in the coal. Longwall machine mining is of comparatively recent development in the United States, and it has been stated by one thoroughly acquainted with coal-mining conditions in Illinois that machines will lengthen the life of the longwall field. A few years ago it seemed as if the thin coal field would have a limited life on account of the cost of mining. The introduction of machinery has turned the scale on many other occasions in mining.

Longwall mining machines are made less than 18 in. in height and of a width permitting them to pass inside props set 30 in. from the face. Years ago the chain had three cutter positions; today it has nine in certain types. These longwall machines require no guide rails or props to hold them up to the working face, and they exert no side pressure on roof props, thus eliminating the danger of falling props due to side pressure of the machines. The anchor jack ahead of the machine is usually sufficient support for the chain which constitutes the feed system while the machine is at work. Figs. 3 and 4 show a machine working under bad top. In Fig. 2 the top seems to have held up at least long enough for the cut to have been made. These illustrations represent the working face at the end of a room or haulageway. In Figs. 3 and 4 the top rock either broke flush with the coal or it was in such shattered condition that it was taken down as a matter of safety. At the right side of Fig. 3 the top seems to be so loose that it might fall at any minute. The chain-feed system of handling longwall machines at times constitutes an element of safety for the machine runner. Thus, in Fig. 3, it may be possible for the machine to proceed by itself, to travel without attention from the runner for a time, or until that portion where the roof is exceptionally broken is passed. The runner may follow it after it has passed the danger point or meet it at the next opening. Also, it is stated that the narrowness and solid construction of the cutter bar make it possible to readily free the bar when jammed by falling coal due to roof pressure. Occasionally the top drops down in a solid mass at the face and it may be necessary to dig out a way back of the fall to allow the mining machine to get by.

The scheme of permitting the machine to proceed unattended would be effective only where there would be no interruption to the steady running of the machine. In the mines of northern Illinois sulphur balls and bands are found in the No. 2 seam and destruction of bits occurs at times when sulphur is encountered. At other times a machine runs along steadily for some distance without the bits having to be changed.

A number of details of machine operation and methods of mining are apparent in Figs. 2, 3 and 4. In Fig. 3 the machine is shown sumping under at a room or haulageway. The cutter bar is partly under the coal; and the method of cutting under to begin work is indicated. In Fig. 4 the machine is emerging from behind the gob and pack wall into view at a room; the runner is at his post at the operating end of the machine, holding the power lever in his right hand. He should keep the machine in the right position relative to the seam, blocking it up with loose coal or rock when necessary on account of uneven bottom. The positions of the feed chain and power cable relative to the machine while in operation are quite clearly indicated.

FIGS 2, 3 AND 4. SULLIVAN IRONCLAD LONGWALL MINING MACHINE AT THE WORKING FACE IN UNION MINE

Fig. 2—Machine under fair top. Fig. 3—Machine sumping under. Fig. 4—Forward or operating end of machine with runner at his post.

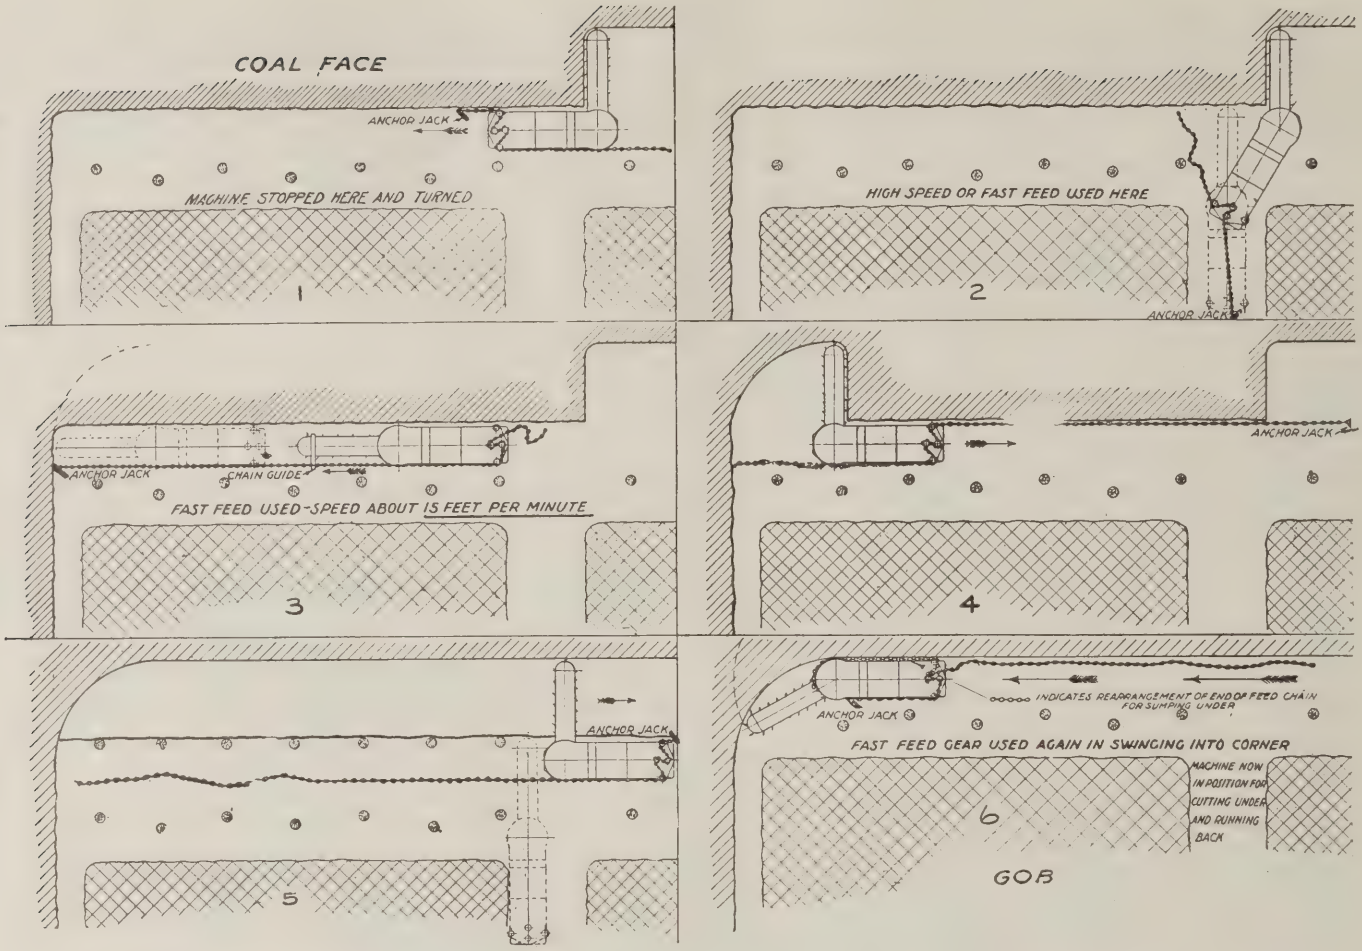


FIG. 5. VARIOUS POSITIONS OF A LONGWALL MINING MACHINE UNDERCUTTING A CORNER IN A MINE

In Fig. 5 is shown one of several methods of undercutting a corner with a longwall mining machine. The cutter bar is arranged so that it can swing through an arc of 190 deg. It may be sumped or cut under the coal with the cutter bar in line with the body of the machine. Under its own power and by manipulation of the feed chain and regular feed, the cutter bar can be swung around into various positions, some of which are shown in Fig. 5. When cutting in either direction the main part or body of the machine travels in advance of the cutter bar. The controlling levers are operated from the front end of the machine, as shown in Fig. 4. The runner also largely controls the movement of the cutter bar, giving it a slight inclination either above or below the horizontal position by blocking up or removing loose material from under the main body of the machine.

Longwall mining has been employed for many years in Great Britain and on the continent, but it has never attained wide popularity in the United States on any extensive scale. It has been confined to a comparatively few localized districts in this country, but its use is likely to be extended as its applicability to the mining of thin seams becomes better known and miners get more accustomed to longwall methods. Longwall mining machines were introduced into Great Britain a number of years ago, and this system of undercutting coal has made rapid advances in British mines. But it is only recently that machine mining has gained much of a foothold in longwall workings in the United States. For many years there has been a determined effort on the part of operators to produce a greater percentage of the larger sizes of coal and reduce the amount of screenings attendant upon both mining and preparation. This incentive and the increasing tendency to utilize machinery about the mines at every possible vantage point indicates a further extension of undercutting machines in longwall work.

For the excellent illustrations accompanying this article *Coal Age* is indebted to the courtesy of the Sullivan Machinery Co., of Chicago, Ill., and to Adam Currie, the superintendent of the La Salle County Carbon Coal Co., through whose assistance the photographs were taken.

Distillation at low temperatures favors the formation of light hydrocarbons of the paraffin series which contain more hydrogen and less carbon than the hydrocarbons of the aromatic group, which are distilled at high temperature. The hydrocarbons of the paraffin series are more stable at high temperatures and on account of their higher hydrogen content are more apt to burn completely without depositing soot than the compounds containing more carbon. It requires one molecule of oxygen to burn completely one atom of carbon, whereas one molecule of oxygen burns completely four atoms of hydrogen. Thus of two compounds having the same number of atoms in a molecule, the one having more hydrogen requires less oxygen for its combustion, and therefore, in the same concentration of oxygen will burn more readily.

What Is the Matter with the Miner?

By A. H. STOW
Pocahontas, Va.

SYNOPSIS—*Why does not the miner load more coal? The average coal digger will produce enough coal ordinarily to enable him to live in his accustomed style, but little more. If the haulage can be so planned that no loader is compelled to wait for cars, he can perform his self-apportioned stint in a short time and may even be induced to raise his standard of a day's work.*

THE question on everyone's lips, the burning question of the hour, is "What is the matter with the miner?" He is certainly paid enough, it is unquestionably his patriotic duty to work, and yet neither of these considerations appears to incite him to mine out more coal. Nevertheless, a simple and natural explanation for this attitude occurs to one familiar with the entire situation. The miner, by dint of industry, could unquestionably double, or nearly double, his earnings of a year ago. Yet were he to double his wages, life, to the average miner, would not be materially brightened thereby, strange as this may seem to the factory worker of the large cities or to the public in general.

In the larger cities, the pleasure that one can get out of life is largely measured by the amount of money that he can get to spend. This, in the average mining camp, is anything but true. The pleasures in the average mining camp are almost too entirely negligible to be worth enumeration. To anyone familiar with the miner's work and with the conditions under which he labors, it is entirely clear that the miner gets about as much pleasure out of a holiday with his friends or with his family, as the case may be, as it is possible for him to get under the circumstances.

Miner Is Actuated by Selfish Motives

From a patriotic standpoint, the miner has not an inch of ground to stand on, so to speak, for not putting his shoulder to the wheel in this critical period. But in the districts remote from the larger cities, which include practically all the mining camps, the people have not awakened to the realization of the seriousness of the situation. Naturally, under these circumstances, the miner is largely actuated by purely selfish motives.

There have been wonderful strides made recently in improving the living conditions around the mines. Within the last few years the improvements in dwellings and in the mining camps generally, owing to the keen competition to secure labor, has been almost startling; and yet, necessarily, the camps are in small isolated communities that do not admit of as large a variety of amusements as the larger cities.

The improvements in the mines have also been equally marked. The mule has been largely superseded by the latest and most carefully designed haulage locomotives. Attempts have also been made, with some degree of success, to improve the mine cars. Speaking generally, the improvements seem almost amazing to one familiar with the conditions that prevailed a few years ago. More, of course, can be done along the lines indicated, and the betterments made by the larger and more progressive companies will no doubt become more general.

However, there is one essential factor that does not appear to have received the attention that it demands or deserves—and a chain is no stronger than its weakest link. The factor referred to is secondary mine haulage. It is not to be inferred that secondary mine haulage is of itself more important than other problems; it is merely that the question of secondary mine haulage today has not received the same amount of attention as other important matters. Naturally, therefore, secondary mine haulage has not shown progress.

Advantages of Secondary Mine Haulage

Until comparatively recently, labor has been in excess of the demand. When this condition prevails, the minimum cost of secondary mine haulage is attained when a sufficiently large number of miners are on any given secondary haul, so that the mule driver or the motorman can always find a loaded car ready almost anywhere. This necessarily means that the miner spends a considerable time waiting for cars instead of being at work. Under the conditions in which the miner lives, it is the number of hours he has to spend underground rather than the actual amount of work done in those hours that he considers a day's work.

With a smaller number of miners on any given secondary mine haul than would be good practice with an excess of labor, the mule driver or motorman occasionally has to wait on the miner to load cars. This results in a somewhat uneconomical secondary haulage cost, and yet it reduces the number of hours that are necessary for the miner in that particular section to stay underground in order to load a given number of cars. Under present conditions this is an important item.

Under normal conditions the increased cost of the secondary mine haulage just referred to can largely be obviated; first, by an ample supply of mine cars, and second, by ample storage space for cars at the gathering parting. Under present conditions it is impossible to make substantial improvements of this kind.

Reducing the average number of miners on the secondary haulage means increasing the number of gathering units, and to add to the number of gathering motors at this time is a serious proposition. For a group of five mines, however, putting one on a mule-haulage basis would give one extra gathering locomotive for the remaining four of the mines—that is, assuming this mine previously had four gathering motors.

Were all mines to make exactly the same improvements along the lines indicated, the result would probably be the same as has accrued from a uniform increase in wages to everyone. The improvements suggested in actual practice are anything but simple and require intelligent handling in order to get results.

Suppose, for example, one mine among a group can materially reduce the amount of time necessary for the

miner to stay underground in order to load the average number of cars requisite for reasonable, comfortable living. When this has been demonstrated to the entire satisfaction of the miners of that mine, the management has a grip on the employees that can be used to material advantage if handled intelligently.

Let us suppose that, at the mine under consideration, a miner can load eight cars in the same time that is required to load five at adjacent mines. The chances are that for the reasons previously given the miner would prefer to load only the five cars, assuming, of course, that it requires only the five cars to afford him the comfort and pleasures in living that he has been accustomed to. However, it is also probable that rather than lose his place at the mine where he can load coal quickly, he will be willing to load six or seven cars.

Unquestionably the improvements suggested mean an increased cost of operation, insofar as the secondary mine haulage in itself is concerned. On the other hand, if the production of a given mine could be augmented through the increased average loading per man, the total average mining costs would be reduced automatically.

Liquid Oxygen Explosives

The Germans have devoted considerable attention to the use of liquid air for blasting purposes, and the Springluft Gesellschaft s.b.H. possesses plants capable of supplying 22 lb. of rectified liquid oxygen per hour, at a net cost of less than one penny per pound. The liquid oxygen is stored in a modified dewar flask, usually of brass or thin steel, the jacket space being filled with charcoal, which absorbs any small amount of gas escaping through the pores of the metal. In utilizing the liquid oxygen for blasting, lampblack has been found the most satisfactory combustible material. Cartridge cases of cardboard are filled with the lampblack, and then immersed for some time in a tank containing the liquid oxygen, so that they become thoroughly impregnated just before use. They are usually fired by a small primer, preferably ignited by electricity. Oxyliquite is stated to be efficient for mining work on account of its *brisant* qualities, but is less suitable for quarry work. It is considered safer than the explosives generally used, since the cartridge is only explosive for 10 minutes ater saturation with oxygen.

Coal will win the War

THE COAL ARMY

Written expressly for COAL AGE
by BERTON BRALEY

The Trapper

I'm only a kid at a swingin' door
  Who's lettin' the coal cars through;
But I guess I'm helpin' to win the war.
I'm doin' my best—an' I can't do more;
  I'm right on the job, are you?

The Pumpman

I keep my pumps a-runnin' an' drive the water out
  So men can do their duty, from collar to the sump;
I'm helpin' lick the Germans, there isn't any doubt,
  By stickin' like a soldier, a soldier at the pump.

The Shaftman

I'm one of the shaft division, who's keepin' the cables fit
  An' watchin' the plates an' timbers, an' seein' that things is right;
For doin' my daily labor is part of my soldier's bit,
  I'm one of the coal mine army, that's helpin' to win the fight;
By lookin' the long shaft over, an' tendin' to its repair
  I'm backin' the boys in khaki who're riskin' it "over there."

The Hoisting Engineer

Hand upon the lever, eye upon the drum,
  Snatchin' up the loaded cars, droppin' empties back,
That's the job they pay me for, makin' cages hum,
  Helpin' put the Kaiser an' his army on the bum!
Coal to make munitions that'll hit the Hun a crack,
  That's the stuff I'm bringin' up, hoistin' from the mine,
Hand upon the lever, eye upon the drum,
  Backin' up the soldiers in the fightin' line!

In the Breaker

Seem's like we're nearer to the front, we boys,
  Than other guys who work around the coal.
You see the breaker makes a lot of noise
  Rumblin' like cannons where the battles roll.
So we kin think we're soldiers in the war
  Fightin' against the dirt an' waste an' slate.
Yes, that's the duty that we're put here for,
  An' we can help by tendin' to it, straight!

The Miner

I'm a sapper, diggin' deep to get the coal,
I'm a first or second cousin to the mole,
  An' my job is to attack
  All the coal seams, rich an' black
An' to make old Mother Nature pay her toll;
So I arms myself with powder-stick an' drill,
An' I works with all my cunning an' my skill,
  For we've got to win, it's clear,
  An' a miner, over here,
Has to do his share in lickin' Kaiser Bill!

Do your share in lickin' Kaiser Bill

Rewinding and Testing Direct-Current Locomotive Armatures

By FRANK HUSKINSON
Lafayette, Colo.

THE average mine electrician is familiar with the rewinding and testing of direct-current armatures, but at the same time I believe that practical men are at all times ready and willing to read a description of the methods and "stunts" employed by the other fellow. It has always been my policy to pass information along, and I feel confident that this short article will not only be welcomed, but that it is needed to clear up mental cobwebs and prevent the rust from accumulating.

A familiar scene is shown in Fig. 1. This is a W-H No. 58 locomotive armature ready for rewinding. In Fig. 2 the same armature is shown partly rewound. Take a glance at old "Long Tom," Fig. 3. This is a Goodman 10-ton locomotive armature, partly rewound, one of the oldtimers. In the foreground of Fig. 4 we have a Crocker-Wheeler 7½-hp. pump motor armature, ready for rewinding, while in the background may be seen a Jeffrey and a Goodman locomotive armature stripped of all coils.

The windings used in direct-current armatures may be divided into two classes—multiple or lap winding, and series, two-circuit or wave windings. The series, two-circuit or wave winding is the kind that will generally be found employed on mine-locomotive armatures, and this type is found in use on nearly all direct-current armatures intended for service in and around coal mining plants.

The characteristic shape of the coils for lap-wound armatures is shown in Fig. 5, while those for wave-wound armatures is shown in Fig. 6. The open-slot type of armature is used almost exclusively in direct-current armatures. The mold-wound coils, which can be used with open slots only, have many electrical and

FIG. 2. ARMATURE SHOWN IN FIG. 1, PARTLY REWOUND

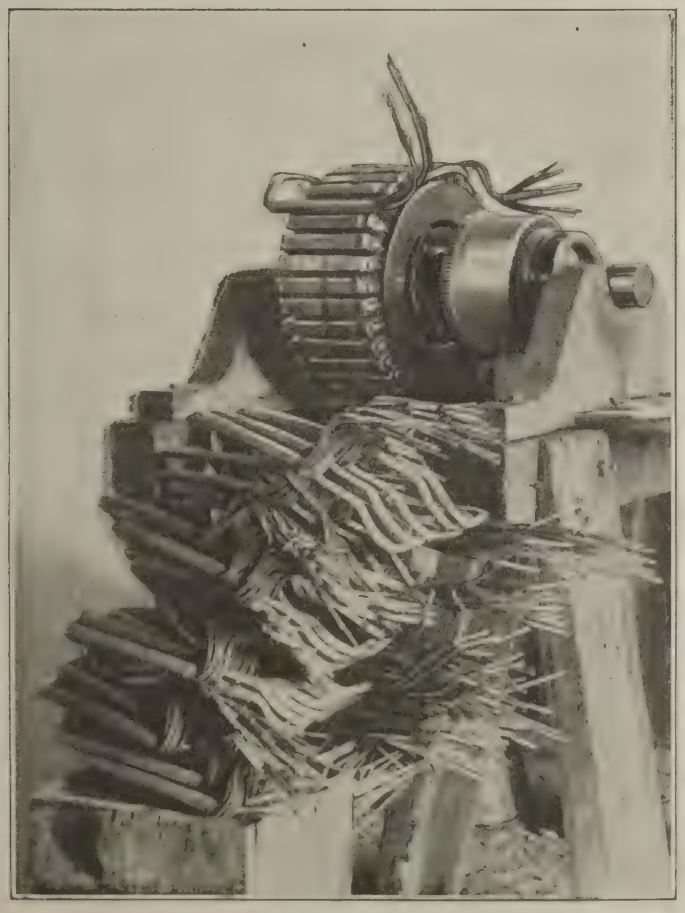

FIG. 1. LOCOMOTIVE ARMATURE READY FOR REWINDING

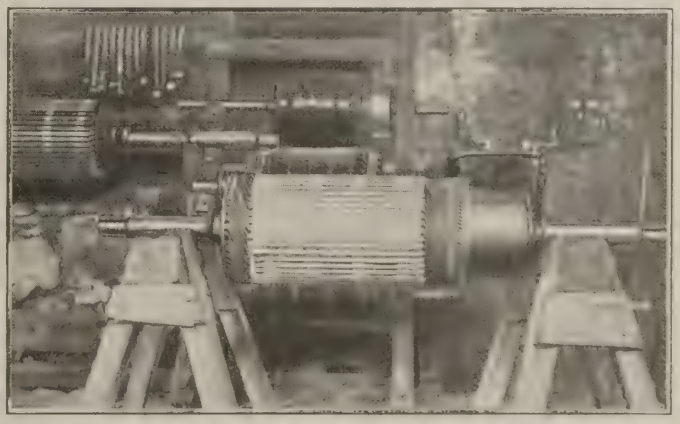

FIG. 3. OLD LOCOMOTIVE ARMATURE PARTLY REWOUND

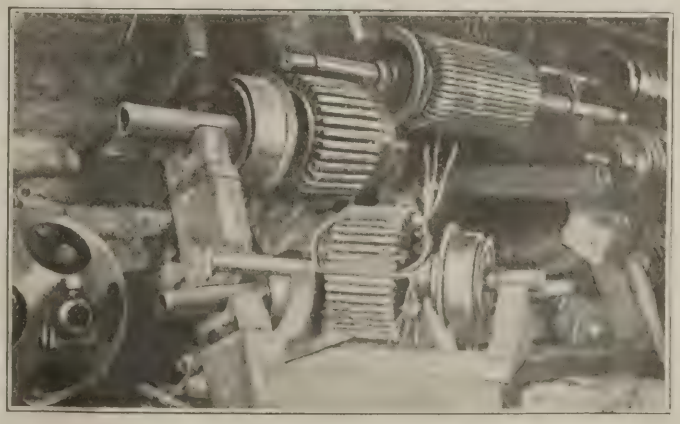

FIG. 4. PUMP AND LOCOMOTIVE ARMATURES

mechanical advantages over the other types, and the open slot has come into common use.

The form of coil generally employed is the diamond coil. This is frequently made in one of the shapes shown in Figs. 7, 8 and 9. In the one-piece series diamond coil, Fig. 7, the leads at the end of the straight parts are either strap- or wire-wound. Fig. 8 shows a

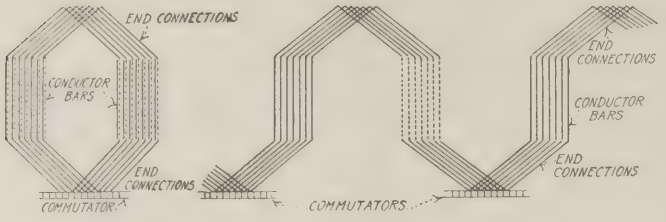

FIG. 5 FIG. 6

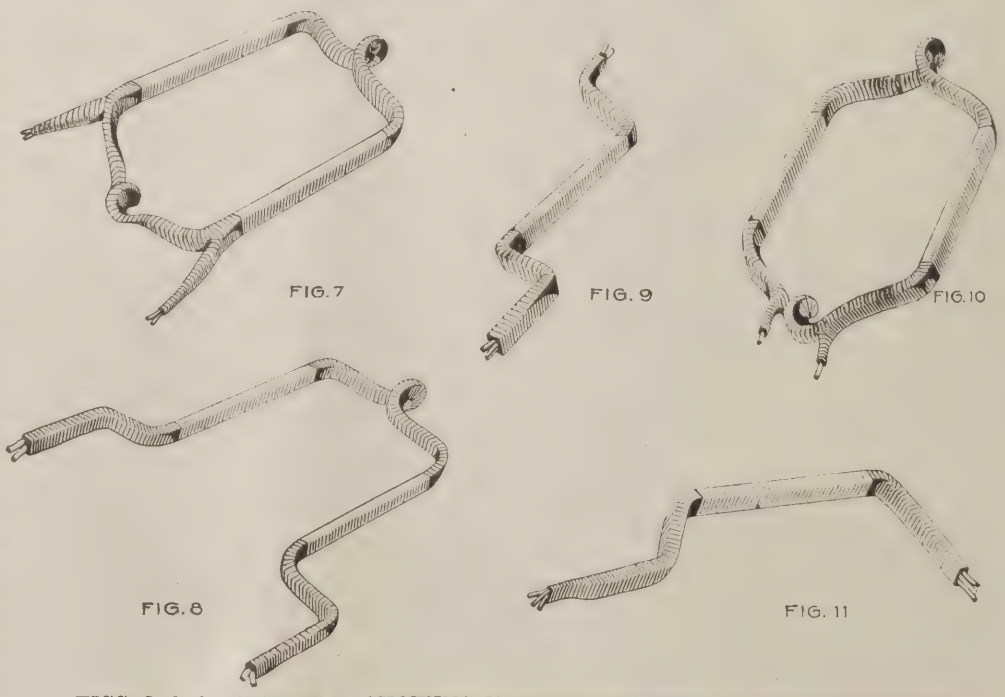
FIGS. 5 AND 6. CHARACTERISTIC SHAPE OF LAP AND WAVE-WOUND COILS

one-piece series diamond coil with leads at the ends of the straight parts. Fig. 9 shows a two-piece series diamond coil, Fig. 10 a one-piece multiple diamond coil with leads at the point of the diamond, and Fig. 11 a two-piece multiple diamond coil.

The diamond coils, when completely insulated before they are inserted in the armature, can be used in open slots only. Their great advantage is the easy and simple manner in which they can be manufactured, especially in large quantities, which makes them well adapted for standard machines.



Since all the coils used on the one type of machine are of the same size and shape, only one winding mold over which to form them is necessary. Moreover, the number of spare parts which must be kept on hand for repairs is reduced, and repairs can be made easily and in a minimum of time.

From the electrical point of view, the diamond type of winding possesses the advantage of being absolutely symmetrical. Hence there is no tendency for the unbalancing of voltages due to the differences of self-induction, and in closed windings there is no tendency to produce internal circulating currents. Pitch, or spread of coils, is illustrated in Fig. 12, which shows a single drum-wound coil in a multipolar field. The sides of the coil A and B should be separated by about the same angle C as the angle D between adjacent poles. The angle C is often referred to as the pitch or spread of the coils, or winding pitch. The angle D is called the angular pitch of the poles. The spread of the coils may differ a little from the angular pole pitch without affecting the action of the machine, but if the difference is large there is liable to be sparking at the brushes. The single-series winding is the principal type in use. In the series type of winding, sometimes called wave winding, the coils are connected to segments removed from one another by approximately the angle of two poles. On a single-series armature the number of coils and commutator bars must always be such that a series of $\frac{P}{2}$ coils connected to bars equidistant from each other will encircle the armature and terminate in a bar adjacent to the one from which the series started. That is, $N = \frac{P}{2} \times Y \pm 1$, in which N is the number of commutator bars or coils, P is the number of poles and Y is a number called the pitch of the connections, or the connecting pitch, it being the number of bars passed over between the terminals of a coil.

In most cases the connecting pitch of an armature is + (plus) 1, commonly called "one over." The advantage of connecting one over is that sometimes in repairing an armature all of the leads are removed from the commutator and it happens that several are broken off close to the commutator. The leads can be reconnected — (minus) 1, or "one under." By this method the broken leads that would have been too short to connect to the commutator one over, will probably reach when connecting one under. The only difference that the change in reconnecting from the one over to the one under will make in any armature is the direction of rotation. That is, changing the armature connections from one over to one under, also changes the direction of rotation in that armature; but as this is a simple matter to adjust at the motor or controller, it will not make any difference.

On four-pole motors the pitch of the coils, or the winding pitch, is usually a little less than one-fourth the number of slots. The throw of the leads must be such that the brushes will rest on bars connected to face conductors in the neutral region.

In the rewinding of any armature the only practical and safe method is the following: The core is cleaned, all slots are filed out, and all sharp corners and edges are removed. The commutator is cleaned and all slots for the leads are cleaned out and tinned. The mica

FIGS. 7, 8, 9, 10 AND 11. SHOWING VARIOUS SHAPES OF ARMATURE COILS

rings on both back and front of the commutator are cleaned and given a coat of shellac varnish, after which a cord band is wound on them. This band is then given a couple of coats of shellac varnish. The commutator is given a thorough test for grounded and shorted bars, with a lamp and test terminals in series. After all the "bugs" are removed from the commutator, all parts of the core that need it should be insulated and painted.

Next find the proper pitch of the coils and the connecting pitch of the leads. For example, assume a four-pole machine, with 35 armature slots and 105 commutator bars, $N = \frac{P}{2} \times Y \pm 1$. In this instance $\frac{4 \times 105}{2} = 52\frac{1}{2}$, called in this case 53, $53 + 1 = 54$, which gives the connecting pitch of 1 and 54; that is, one lead of the coil connects to bar 1 and the other end of this coil connects to bar 54. The next coil leads connect into bar 54, then connect to bar 107, recounting the bars 1 and 2, see Fig. 13. This is called

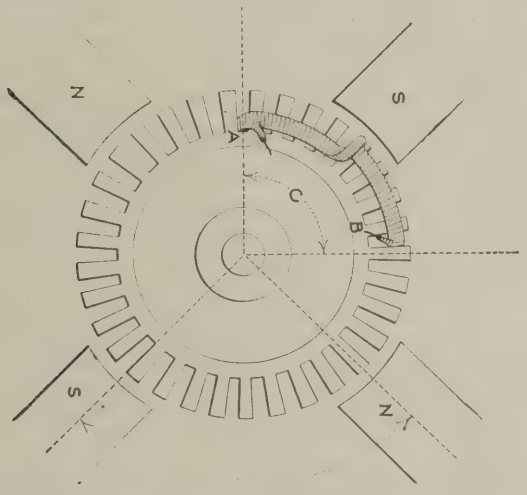


FIG. 12. ONE COIL IN A MULTIPOLAR FIELD

one over, or plus. The connections can also be made as shown in Fig. 14. This is called one under, or minus.

After determining upon the proper slot pitch of the coils and the connecting pitch proceed to put in all of the coils, using the proper amount of insulation in the slots and between the parts of the coils, etc., and keeping them shaped properly. As each coil is placed in the slots the bottom leads are connected to the commutator. The proper slot pitch for the armature in the example chosen—that is, with 35 armature slots—will be 9. This means that the top part of the coil will go into slot 1, while the bottom part will go into slot 9.

After all the coils are in place, and all of the bottom leads are in the commutator slots, tie a wire around the commutator so as to short-circuit, or connect all the commutator bars together, and then make a test for grounds. Remove this short-circuiting wire and cut off all surplus from the leads that are connected to the commutator; separate all of the top leads, and make a test for rotation as follows: Place one terminal of the lamp-test set on a commutator bar, marking this bar, then with the other test terminal touch the top leads until the proper coil is found—that is, until a coil lead is found that the lamp will light up on. Still leaving the test terminal on the same bar, touch the leads on each side of the one where the lamp lights up. Getting no light from these leads indicates that the lead that the lamp lights up on is O. K.

If the lamp lights up on more than the one lead at a time, it indicates that the leads are either crossed or shorted together, or else the commutator bars are shorted together. Make this test all the way around

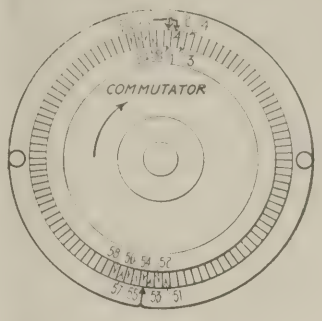

FIG. 13

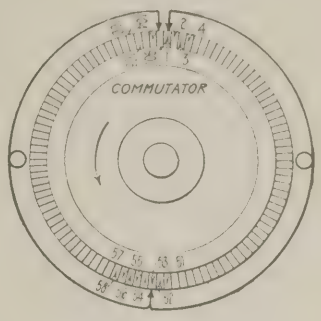

FIG. 14

FIGS. 13 AND 14. ONE OVER AND ONE UNDER WINDINGS

the commutator by moving the test terminal one commutator bar at a time, and then touching the top leads with the other test terminal until the lamp lights up. The top leads should test out in rotation. As the leads are tested separate them and lay them out in rotation as they are to go in the commutator.

Next insulate the bottom leads and find the proper connection for the top leads. Then proceed to put in the top leads all the way around the commutator. When all the leads are in place make another test for grounds. In making this second test for grounding it is not necessary to tie a wire around the commutator as the coils are all interconnected now. Finding the armature clear of grounds, make a test for circuit by touching the test terminals of the lamp test set, on the commutator. The lamp should light up no matter to what parts of the commutator the test terminals are touched. Finding everything all right, the next step is to solder all leads in the commutator and shape all coils to place, then give a coat of thin shellac varnish or other insulating paint. Next insulate and put the band wires on, taking care that the tension on the band wire is steady and fairly tight. The proper tension to use in

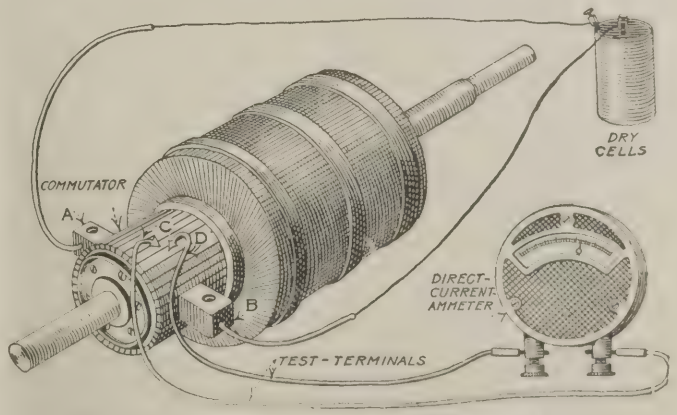

FIG. 15. HOMEMADE TEST SET IN OPERATION

banding an armature is a matter of judgment on the part of the winder, since this depends on the size of the armature and size and kind of band wire, also the speed and the service at which the motor is to be used. Solder the bands and give the clips a little extra solder;

then true up the commutator by putting the armature in a lathe and taking a cut or two off the commutator. Next proceed to make the following tests: Test for ground, then successively make a bar-to-bar test for open circuits, short circuits, poor connections and reversed leads.

A reliable and satisfactory test set that can be made at any mine and used in making the bar-to-bar test is shown in Fig. 15. It is constructed as follows: Take a common switchboard or portable ammeter, direct-current type, and leave out the shunt. Connect two test terminals as shown at *C* and *D;* connect about four dry cells in series to the points *A* and *B*. On the commutator of some armatures it is necessary to move these points closer together than is shown in the diagram, in order to get a reading on the ammeter. This can be found only by test. Take the two test terminals *C* and *D*, and touch adjacent commutator bars. If the

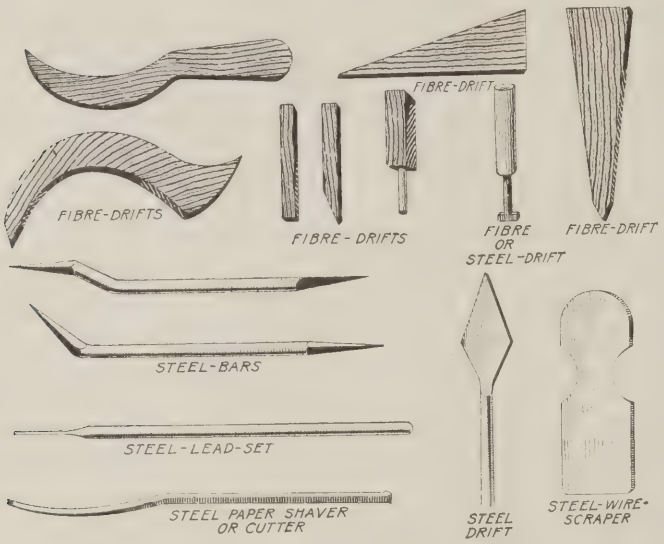

FIG. 16. A FEW ARMATURE REWINDING TOOLS

coils are all right the ammeter will read approximately the same on every two bars between *A* and *B*. After testing all bars between the points *A* and *B* move the points *A* and *B* around a little and test again until all of the commutator bars have been tested in this manner.

If a coil or a commutator bar is shorted the reading on the ammeter will be practically zero. If the coil is open-circuited there will be no reading on the ammeter until the open is bridged by the test terminals, when there will be a very high reading, throwing the ammeter needle violently across the dial. If the coil is reversed—that is, if the leads are crossed—the reading on the ammeter will be reversed. If the coil is poorly soldered or connected to the commutator bars the reading on the ammeter will be high. A little practice will enable anyone to make rapid and thorough tests with a test set like the one just described.

In the rewinding of any armature the success of the winder depends greatly upon the methods employed. In rewinding an armature it is advisable to be careful, neat and particular from the start to the finish. Never get in a rush and start to slap the coils or connections in any old way, as this does not pay. Do not strike a coil with a hammer; always use a piece of fiber between the coil and the hammer. A rawhide hammer is useful in rewinding, as the blows from such a hammer will not damage the coils. In tapping the coils into place and into the slots always use a fiber drift of the proper size and shape. In Fig. 16 are shown a few of the common armature-rewinding drifts and tools.

All armatures after rewinding should be tested for balance. The armature is mounted on two exactly horizontal knife-edges. If it shows a tendency to rotate, it is out of balance. Weights are applied wherever needed to correct unbalancing.

Legal Department

FORFEITURE OF LEASES FOR NONPAYMENTS.—Before a court will decree forfeiture of a mining lease because of failure of the lessee to make stipulated payments, it must appear that the lessor, not only has an equitable right to forfeiture, but also that he cannot obtain adequate redress by means of suit to recover the payments due. (Indiana Appellate Court, Rembarger vs. Losch, 118 Northeastern Reporter, 831.)

NEGLIGENCE AS TO UNEXPLODED CHARGES.—If an unexploded charge of dynamite was negligently left in a mine entry wall, and the operator's foreman negligently permitted plaintiff, a miner, to work at the place, drilling a hole nearby, and injury resulted to plaintiff, the assignment of plaintiff to work at that point constituted actionable negligence, entitling him to recover. (Oklahoma Supreme Court, Corrigan vs. Oklahoma Coal Co., 171 Pacific Reporter, 47.)

INJURY TO UNINVITED PERSONS.—The fact that defendant company gratuitously furnished one of its engines and flat cars, used exclusively in coal-mining operations, to convey the remains of two of its miners, who had been killed at work, and their friends and relatives to the cemetery where interment was made, did not render the company liable for accidental injury to plaintiff, who boarded the car without invitation and rode on the return trip and who fell to the ground while one of defendant's representatives was assisting the persons on the car to alight by means of a plank placed from the ground to the car; there being no proof of any wanton or positive negligence on the part of the company or its employees. (Kentucky Court of Appeals, Laxton vs. Wisconsin Steel Co., 201 Southwestern Reporter, 15.)

WHEN AN OPERATOR MUST AFFIRMATIVELY DISPROVE NEGLIGENCE.—The general rule of law that when an employee sues to recover damages the burden rests on him to affirmatively establish negligence for which defendant employer was legally responsible is modified in Iowa by the drastic provision of the Workmen's Compensation Act: "In actions by an employee against an employer for personal injury sustained, arising out of and in the course of the employment, where the employer has selected to reject the provisions of this act, it shall be presumed that the injury to the employee was the direct result and growing out of the negligence of the employer; and that such negligence was the proximate cause of the injury; and in such cases the burden of proof shall rest upon the employer to rebut the presumption of negligence." Applying this provision in the case of Mitchell vs. Phillips Mining Co., 165 Northwestern Reporter, 108, the Iowa Supreme Court holds that plaintiff having proved that a miner sustained fatal injury through a fall of slate from defendant's mine roof, while the miner was performing duties of his employment, and that defendant had rejected the provisions of the Workmen's Compensation Act, the proof was sufficient to sustain recovery against defendant, in the absence of affirmative proof by defendant of its freedom from negligence.

A Uniform Cost Sheet

SYNOPSIS—*Each operator presumably has filled out Federal Trade Commission blanks, reporting on the monthly coal cost, income and coal tonnage for the current year. He is supposed to be familiar with the details of this task. Nevertheless, there has been some uncertainty as to just what is required in this report. The Winding Gulf Operators' Association considered it worth while to have a committee, made up of members from its organization, thoroughly investigate the whole matter. The report of the committee on the uniform cost sheet, with instructions as to its use, is most timely and the suggestions made should be of interest to operators generally. A full discussion of this matter might influence new rulings which are expected to be made for the year 1919.*

"COAL is costing too much. I noticed by our cost sheet this morning that it was 11c. higher last month than the preceding month, and we will have to locate the items which caused this and do better." This statement was made by the general manager of a large coal company to his superintendents of mining and preparation. It suggests one successful method of management. When the total cost seems excessive, a careful analysis of all the items entering into the mining and preparation of coal would often enable a manager to put his finger on the trouble at once without going out of his office.

Another equally successful manager might get at the matter in an entirely different way. If the cost of placing coal on cars was too high, he would depend on locating the trouble out on the ground. It is difficult to find this manager in his office. He spends his time out around the breaker or tipple, down in the mines and at every point about his plant where men are at work, where supplies are being used, noting the efficiency or failure of methods. Both men emphasize the importance of attention to details. One man reads his cost sheet, the other depends more on personal observation.

Question of Costs Now Receiving Attention

Today most of the large coal companies and the more progressive operations have more or less elaborate cost sheets in which all the items entering into expense and receipts accounts are carefully distributed. During the last year or so great attention has been given to costs all over the United States. This is due in many cases to the impetus given the matter by the Washington authorities. In this connection a report of a committee of the Winding Gulf Coal Operators' Association of West Virginia is most interesting. The members of this association are operating in the southern part of Raleigh County, West Virginia, on lines of the Virginian and the Chesapeake & Ohio railroads. The committee in question, after a thorough investigation reported on the uniform cost sheet of the Federal Trade Commission with instructions as to its use; a local interpretation is given to some features of the standard cost sheet for the guidance of the association's members in filling out the required monthly report. However, the operators in the field in question are progressive and their opinions should be of interest to coal men not only in other sections but also in other states.

This report notes that the United States Fuel Administrator has stated officially that the question of the selling price of coal is one that is open to constant review; that cost engineers are continually examining the cost sheets in all the coal districts in the country. The Winding Gulf committee finds that one of the most important questions in the coal-mining business today is to see that the proper charges are made against the cost of coal. It is of special importance that each individual operator returns as fair and accurate a cost report as practicable, in view of possible future adjustment of the selling price of coal.

Note is made that the basis upon which the selling price is fixed is entirely upon cost. Since this report was published the Fuel Administration has ruled that a bonus of 20c. a ton may be added to the Government price in the case of operators who use special means for eliminating inpurities. Later a further effort to insure the loading of clean coal was made in an order enforcing operators who failed to comply in this respect to either clean the coal or accept 50c. a ton less than the Government price. The committee earnestly recommended that a uniform system of coal cost accounting be seriously considered by each individual operator with a view of standardizing all accounts. It would greatly facilitate the work of the Federal Trade Commission and the Fuel Administration if all operators acted on this suggestion.

Scope of the Standard Cost Sheet

The 1918 standard cost sheet seeks first of all to arrive at the total mining cost, which is divided into labor and supplies. Labor is subdivided as follows: (a) Mining; (b) yardage; (c) haulage; (d) tipple; (e) removing stripped coal; (f) power; (g) washery; (h) other operating labor; (i) maintenance and repairs—(1) structures, (2) equipment; (j) superintendence and engineering. In its report the Winding Gulf committee disregards the items (e) removing stripped coal and (g) washery, as these accounts do not enter into the costs of the Winding Gulf operations.

Each of the subdivisions has a further subdivision. Supplies are subdivided as follows: (a) Mine timbers; (b) feed and other stable supplies; (c) power house fuel; (d) power purchased; (e) water purchased; (f) washery supplies, including water; (g) other operating supplies; (h) maintenance and repairs—(1) structures, (2) equipment. The items (e) water purchased and (f) washery supplies are disregarded in the Winding Gulf report and an additional account, "explosives used," is specified. In connection with the item (b) feed and other stable supplies, note is made that operators should inventory their stable account at the end of each month and close the account for the month. The labor at the stable should be charged under the head of "haulage." The feed used should be charged to "feed and other stable supplies." A stable account should be opened at

the beginning of each month, charging it with the inventory of the previous month.

The Winding Gulf report states that the gross cost of labor and supplies is now complete. To obtain the total operating cost several other items should receive consideration. Among these items is the profit or loss on the powder house; to obtain this the inventory of the magazine should be taken at the end of each month. The magazine account should be opened on the first of each month, charging it with the stock on hand. The gross returns from smithing should go into this operating account as well as the gross returns from the power house and the substation. The net debit or credit balance for mine checks, unclaimed wages and any other accounts in the mining business should be considered, and the total debit or credit either added or deducted to obtain the total operating cost.

Under fixed charges and general expense are included (a) royalty, (b) depletion and (c) depreciation. Royalty is arrived at on leased lands according to the terms of the leases. As to depletion, the Winding Gulf committee states that some confusion exists as to the correct interpretation of the matter. The committee advises those who purchased property prior to Mar. 1, 1913, to deplete on the value en bloc as of Mar. 1, 1913. If purchased after that time deplete on the original cost, on the assumption that this position will be sustained by the courts.

In regard to depreciation the committee states that the question of depreciation on mining property is one about which no two people hold the same view. This is a most interesting and important matter; after diligent research and much investigation the following was recommended by the committee: All structures which are directly engaged in the mining of coal should be listed at their original cost under this head; all equipment used directly in the mining of coal should be listed at original cost and be placed under this head; all development of mines in question, including the sinking of shafts and slopes, the driving of tunnels through faults over 50 ft. in length (other development work of like character should be included) should be listed and be placed under the head of development. These three items together with a fourth—(d) miscellaneous income—are all taken into account in the cost of coal. Under this last item are included outside investments not included in the first three classes.

After the structures account has been opened up the following depreciation is recommended:

	Per Cent.		Per Cent.
Wooden tipples, complete	8	Churches and schools	4
Steel tipples, complete	5	Squire's office and jail	4
Wooden power house (building)	7	Sand houses	4
Stone or brick power house	5	Postoffice building	4
Machine shop—wood	8	Substation—wood	7
Machine shop—stone or brick	5	Substation—stone or brick	5
Supply house—wood	8	Humidifier building—wood	7
Supply house — stone or brick	5	Humidifier building—stone or brick	5
Blacksmith shop—wood	8	Powder house — concrete, stone or brick	10
Blacksmith shop—stone or brick	5	Wash house—wood	10
Stable building—wood	8	Wash house—stone or brick	5
Stable building — stone or brick	5	Fireproof vaults	4
		Freight stations	10
		All other small buildings	10

After the mine development account is opened up, depreciate as follows:

	Per Cent.		Per Cent.
Clearing property	5	Diamond drill holes	5
Creek changes	5	Tram roads	20
Wagon roads	5	Mine development	10
Slopes and shafts	5		

After the equipment account is opened up depreciate as follows:

	Per Cent.		Per Cent.
Dynamos and engines	8	Mine wagons (cars)—steel	17
Boilers	11	Mine locomotives	10
Pumps, heaters and other power house equipment	8	Mining machinery	20
Header lines	8	Electric drills	20
Fans	5	Stable equipment	25
Water tanks	7	Patent mine doors	20
Railway sidings and approaches	7	Copper wire	7
Humidifiers	12½	Supply house fixtures	10
Telephone lines	10	Post office equipment and fixtures	7
Saw mills	10	Fire equipment	20
Hoists	7	Air compressors	8
Incline drums and larries	10	Good roads machinery	10
Incline ropes	33⅓	Shop fixtures and machinery	7
Cage ropes	50	Stationary motors	7
Hoist engines	7	Watchmen's clocks	10
Mine telephones	20	Pipe lines in mines	33⅓
Mine pumps	20	Barber shop fixtures and barber shop	10
Steel rail	10		
Mine wagons (cars)—wood	20		

In connection with the miscellaneous building and fixtures account, depreciate as follows:

	Per Cent.		Per Cent.
Theater building	6	Store and office buildings —stone or brick	5
Theater building fixtures and poolroom	20	Furniture and fixtures in same	10
Store and office buildings —wood	6	Tenement houses	6
		Club house furniture	15

It is assumed in charging up the various depreciation items against coal that the revenue derived from this source will constitute a working capital and not be distributed as dividends. It is further assumed that the depreciation percentages given are for one year and that this fact is taken into account in making out monthly reports.

Before arriving at the total mining cost of coal, there are a number of other charges which should receive consideration. Among these are deferred charges, incuding unrecoverable royalty, which will have to be figured out in individual cases. Further, the executive committee of the National Coal Association advises that an account be opened up under the head of special maintenance, to which should be charged coal at the rate of 5c. per ton to take care of the abnormal cost in the present mine equipment. In other words, to charge to this account those parts of the cost of material and equipment which are above normal prices and which are used in capital accounts only. Then gradually work off, through this 5c. per ton per month, the abnormal cost of material and supplies going into capital accounts.

The Winding Gulf committee also would open up a contingent account to take care of explosives and other damages beyond human control. After due investigation and advice the committee feels that special maintenance and contingent accounts should be included, notwithstanding the fact that they have not been allowed by the Federal Trade Commission.

It is advised that all state excise and corporation taxes, county taxes, United States Government stock taxes, and, in fact, all taxes except United States income and excess profit taxes should be charged and prorated to the different departments to which they belong. The suggestion is made that the previous year's taxes along these lines be taken and then apportioned one-twelfth of that amount each month and charge it up to the proper departments. Set this amount off as a reserve for these taxes and the last month in the year reconcile this account with the amount actually paid.

Similarly with insurance. The premiums on all fire insurance that properly belong to the mining property directly engaged in the mining of coal should be charged

to the cost of coal. Thus the insurance on the store building and stocks should be charged against the rent account; fire insurance on other subsidiary lines of business, not directly engaged in the mining of coal, should be charged to the proper account. It is further advised that the entire amount of premium paid for explosion and use and occupancy insurance be charged against coal under the head of general insurance. It is suggested that the total cost of all this be figured out from the policies for one year and then one-twelfth of the total amount be charged each month.

All officers' salaries and office expenses, with some possible exceptions (in West Virginia—the scrip clerk), should be charged against coal. If there is a shipping clerk or clerks of any kind who spend their time at the mines, their time should be included in the two items, officers' salaries and office expenses. All legal expenses except those expenses incurred for personal injury accounts or legal expenses incurred in acquiring new property should be charged against coal under the item legal expenses. The total operating cost and the total fixed charges and general expenses are now available; adding these costs, charges and expenses together gives the total mining cost of coal.

The committee now turns to coal tonnage. This should include the tonnage furnished employees, or sold at the mines, power house, and shipments—rail or otherwise. This tonnage is to be taken from the returns from sales agents for the coal shipped and the accounting of the company's force at the mine for coal used and coal delivered at the tipple. Following the tonnage, as to quantity, is a space for recording the cash returns for coal sales. This account is made up from the returns from sales agents together with the accounts kept at the mines for coal used and coal furnished.

Under coal inventories are spaces for an inventory at the first of the month, at the end of the month, and increase or decrease, as the case may be. Under production tonnage are included total sales derived from detailed tonnage accounts. If coal has been purchased it should be deducted from total sales. The inventory should be added in event of increase or deducted in case of decrease. The final result is the production tonnage for the month and represents the coal dumped over the tipple. It is the divisor to be used to divide the total mining cost previously obtained.

As to selling cost—this includes (a) commissions, (b) advertising, (c) salesmen's salaries and expenses, (d) officers' salaries and expenses, (e) clerical salaries and office expenses, (f) uncollectible accounts and (g) miscellaneous. There are two columns under selling cost—amount for the current month and the amount Jan. 1 to and including the current month. The committee did not instruct definitely under this head, as many of the operators have contracts with selling agents who remit net at the mines so much per ton. To such operators this fact should be thus stated on the return. Many operators sell their own coal, have pooled their interests with others, or have special arrangements with selling agents. Those operators who make a return on selling cost should include the tonnage returns by the sales agents and the coal sold at the tipple. Coal used in a power house should not be considered, as it carries no cost for selling.

Under income statement, the Federal Trade Commission endeavors to arrive at the real money a company has received. Little comment seems to be necessary up to the point where the profit from coal is noted. Under miscellaneous income the Winding Gulf committee states that the operators should show the profit or loss each month from their dwellings. Dwellings should be credited for rent collected and charged with ordinary repairs, with their proportion of the insurance, taxes and depreciation. Also the stores and any other part of an operator's business indirectly engaged in the mining of coal should be so handled. As the Winding Gulf fields at this time have no private transportation lines or coke ovens, these features are not touched upon. However, net receipts from any other profits, as well as proper depreciation charges, should be included in miscellaneous income. Under deductions from income are noted (a) taxes (income and excess profits) and (b) interest. The committee considers that these items are more or less in the nature of an estimate; a reserve should be set aside each month on a company's books. When the annual income and excess profit tax is paid, the amount should be charged to the tax account and the cash account be credited. Similarly with the interest.

In connection with charges to fixed assets, the committee reports that if a company has spent any money on its property in the way of betterments that these amounts should be included.

Under general information the comment is made that the Federal Trade Commission has advised that the word "semi-bituminous" be used in answer to the kind of coal. Further, that for the field in question that "New River" be used in the column marked field; and that "Beckley" be used for number or name of seam—or "Sewell" or "Pocahontas," as the case may be.

The Winding Gulf committee concludes with the statement that it "has labored patiently with reference to this whole question and respectfully submits this report with the understanding that, in its opinion, it is the best advice and information that can be furnished at present on this matter. The whole question of coal cost accounting, as laid down by the Federal Trade Commission, as outlined in the foregoing, is good only for the year 1918. No doubt as we progress further along in this matter, new ideas and rulings will be made for the year 1919."

The report is submitted to E. E. White, president of the Winding Gulf Operators' Association, and is signed by E. B. Wray, D. C. Wade, F. K. Bowles, C. R. Stahl, R. F. Roth and George Wolfe, chairman. W. G. Caperton is the treasurer and J. H. Hatcher secretary of this association.

The conversion of the volatile matter of bituminous coal into liquid fuel seems to be even more promising than its conversion into gas. By the application of proper processes it seems possible to reduce a large part of the volatile matter of liquid, of which an appreciable percentage can be obtained in the form of light oils suitable for motor fuel. Benzol has been obtained at byproduct plants for many years without any special effort to produce it. There is no doubt that with well-developed methods the yield of benzol and similar oils could be greatly increased.—*Bureau of Mines Bulletin No. 135.*

Determination of the Proper Size of Storage-Battery Locomotive

By DEVER C. ASHMEAD
Tarrytown, N. Y.

SYNOPSIS — *Two important considerations govern the selection of a storage-battery locomotive—drawbar pull and battery capacity. The maximum drawbar pull is easily determined. The battery capacity depends upon the amount of actual work to be performed between chargings and necessarily involves considerable calculation of loads, grades, speeds, etc. These calculations are here explained.*

ALTHOUGH storage-battery locomotives have been used in a few mines for as long as eight or nine years, only within the last two or three years have they come into general use. Many operators do not yet understand them sufficiently to be able to decide on the proper size, and therefore have to rely entirely on the advice of the salesman who is selling these machines.

This is satisfactory in most cases, since the salesman is usually well versed in his own business. He is likely to make mistakes, however, which may be costly. A few instances have occurred (when competition has been severe) where a salesman has cut down the size of the battery in order to reduce the price so that he might get the order. Fortunately this rarely happens, as it is unusual for a salesman to sacrifice quality in order to make a sale.

The prospective purchaser of a locomotive should at all times be in a position to check the statements of a salesman or manufacturer and satisfy himself that the locomotive in question will do the work required of it. This knowledge I have endeavored to embody in this article, which is based on an experience gained in the installation and observation of more than 50 storage-battery locomotives.

Proper Size Is Important

After the operator has decided on the use of storage-battery locomotives, and has come to the conclusion that they can be used successfully in his mine, the next thing to determine is the proper size necessary to do the work. A locomotive that is not large enough will not do the required work, while one that is too large means a waste of power and money.

The first fact to know about a locomotive is the relation of its weight to its drawbar pull. This varies in the different types of locomotives; in other words, all locomotives will not have the same maximum drawbar pull for the same weight, but all such machines of the same weight, type and construction will have the same drawbar pull. At the present time there are seven different types of locomotives on the market. Table I enumerates the various varieties, with the relation between the drawbar pull and weight of the machine expressed in percentage of the weight of the locomotive. This relation is shown for both starting and running and is based on dry, clean sanded rails.

TABLE I. RELATION OF DRAWBAR PULL TO WEIGHT OF LOCOMOTIVE

Type	Total No. of Wheels	No. of Motors	No. of Driving Wheels	No. of Trucks	No. of Drivers on Each Truck	Type of Wheel	Percentage of Drawbar Pull to Weight: Running	Percentage of Drawbar Pull to Weight: Starting
1.....	4	1	4	1	4	C.C.I.	20	25
2.....	4	2	4	1	4	C.C.I.	20	25
3.....	4	2	4	1	4	S.	25	33⅓
4.....	8	2	4	2	2	C.C.I.	17½	20
5.....	8	2	4	2	2	S.	20	25
6.....	8	2	8	2	4	C.C.I.	25	30
7.....	8	2	8	2	4	S.	30	35

C.C.I. = Chilled cast iron. S = Steel.

Knowing the different types of locomotives, and the one that is preferred, it is easy to determine the percentage of the drawbar pull to the weight of the locomotive from Table I.

In order to ascertain the proper size of driving motor it is necessary to know the grades on which the locomotive will operate and what load it will have to handle over them. The grades can be determined from track levels, or if the locomotive is to be used in a part of the mine in which there has been no work done, it may be advisable to take part of the mine where the conditions are about what are expected and assume that these grades will be actually encountered.

The maximum load is easily determined. This depends on how many cars will be handled per trip on a heading and what each holds.

Friction May Vary Considerably

The next point to consider is the amount of friction that the locomotive will have to overcome in order to move the train. This friction may vary from 10 to 40 lb. per ton of train weight. The friction depends entirely on the track conditions and the type and condition of the rolling stock. If the rail is heavy, the track well ballasted and in good alignment, the curves elevated and not too sharp, and the cars have well oiled roller bearings, the friction may be as low as 20 lb. per ton or even less for the train, and the locomotive may have a friction as low as 10 lb. per ton. If the rail is light, track poorly ballasted and crooked, curves flat and sharp and the cars have plain bearings, the friction may be as high as 40 lb. per ton of train weight. The prospective purchaser of a storage-battery locomotive must determine what condition his track is in and about what friction the locomotive will have to overcome. This friction can only be estimated.

The maximum load in tons that locomotives of various sizes can handle on various grades with different amounts of friction is shown in Table II. Knowing the maximum load that will have to be handled over the worst grade, and having estimated the amount of rolling friction per ton, the proper size of locomotive can be determined readily. The table is self-explanatory.

Having fixed on the size of the locomotive, the next step, which is probably the most important, is to determine the size of the battery to supply sufficient power to do the required work. Fig. 1 gives the drawbar pull necessary to move any load up to 220,000 lb. up any grade not exceeding 12 per cent., and with different amounts of rolling friction. Knowing the different grades that the locomotive will operate on and the load that it will have to handle up these grades, the drawbar pull necessary to move this load can be obtained for each and every grade.

Fig. 2 gives the watt-hours that will have to be drawn from the battery in order to furnish sufficient power to produce any necessary drawbar pull up to 7000 lb., and for any distance up to 5000 feet.

Therefore, knowing the drawbar pull from Fig. 1, and the length of the grade that this pull will be used on, from Fig. 2, the watt-hour consumption can be found. It will be noticed that there is no allowance made for negative grades or those in favor of the load, as with few exceptions there will be practically no drawbar pull required here. When a small drawbar pull is necessary the minus grade can be assumed to be level and the drawbar pull assumed as that for level track.

The next quantity to be determined is the time that the motor will require to make a round trip. It is necessary to have this information in order to determine the number of trips per day, so that the number of times the locomotive passes over a certain grade will be known.

Knowing the times the lomocotive will pass over the various grades, the next step is to multiply the watt-hours for each grade by the number of times the locomotive traverses it. The total will represent the number of watt-hours that the battery will have to produce in order to do the work required.

Having determined the watt-hour capacity of the battery, the next step is to decide on the type of accumulator and the size of the individual cell. In this, much will depend on the preferences of the individual oper-

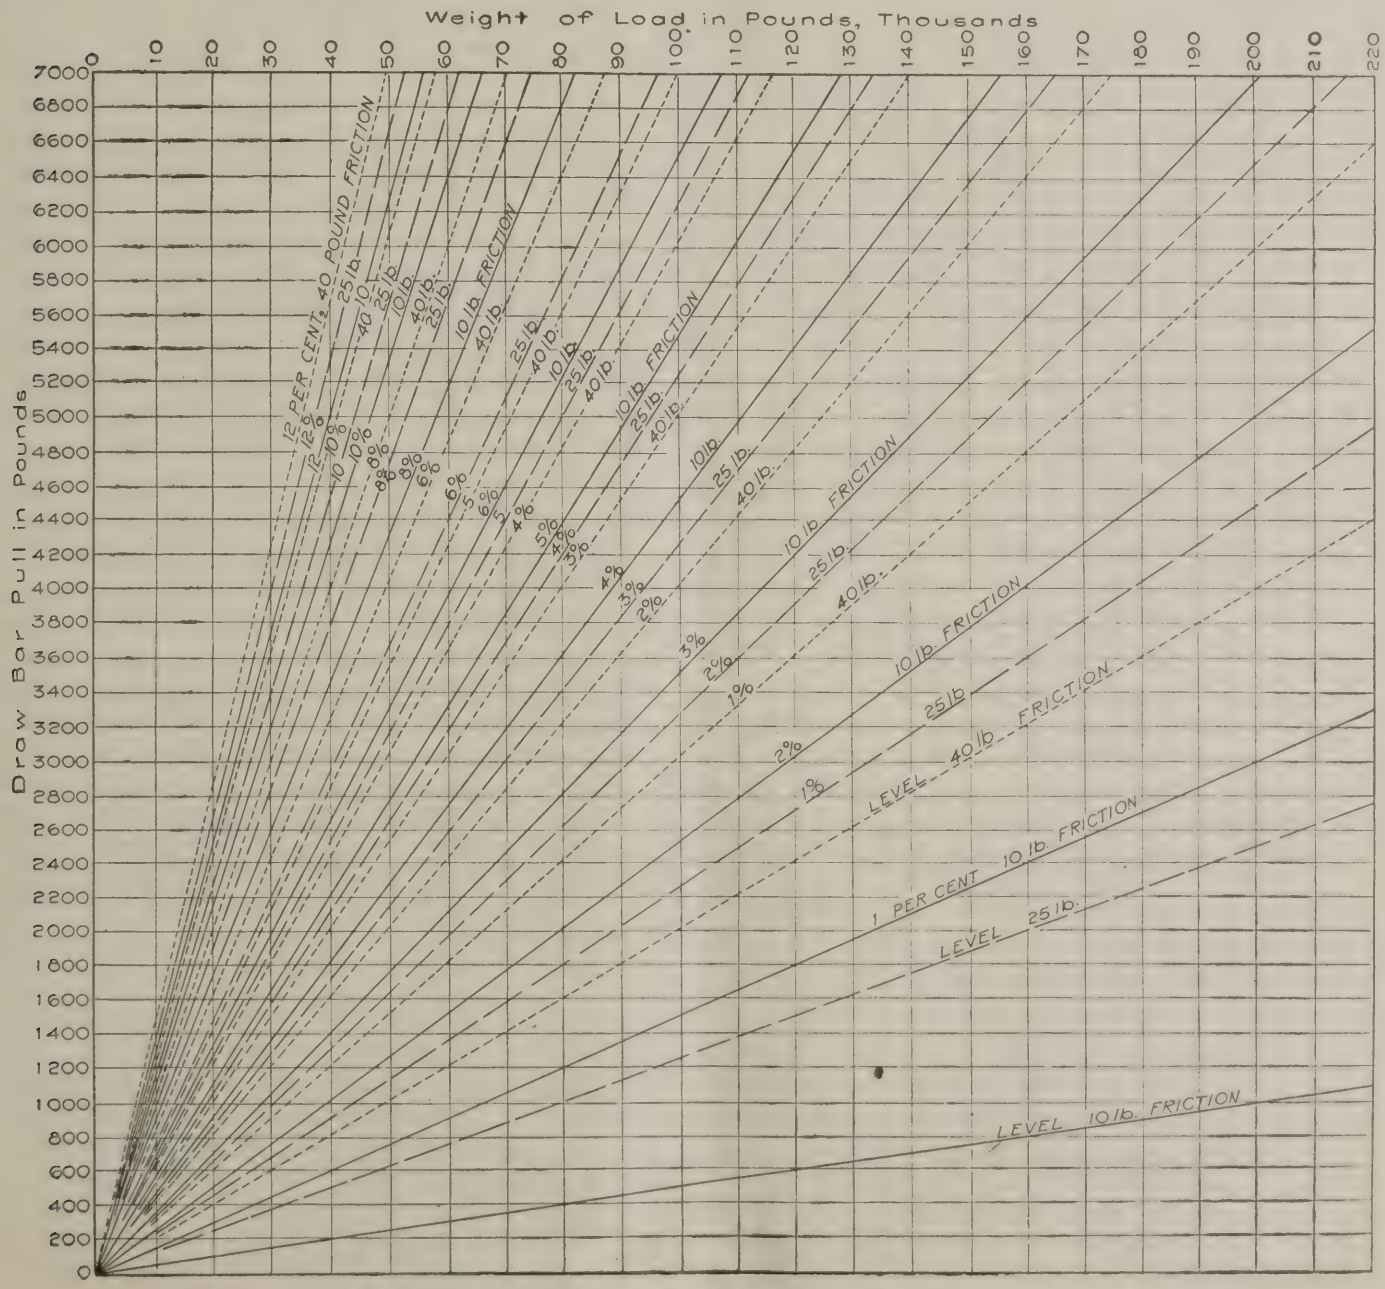

FIG. 1. DRAWBAR PULL FOR VARIOUS LOADS, GRADES AND COEFFICIENTS OF FRICTION

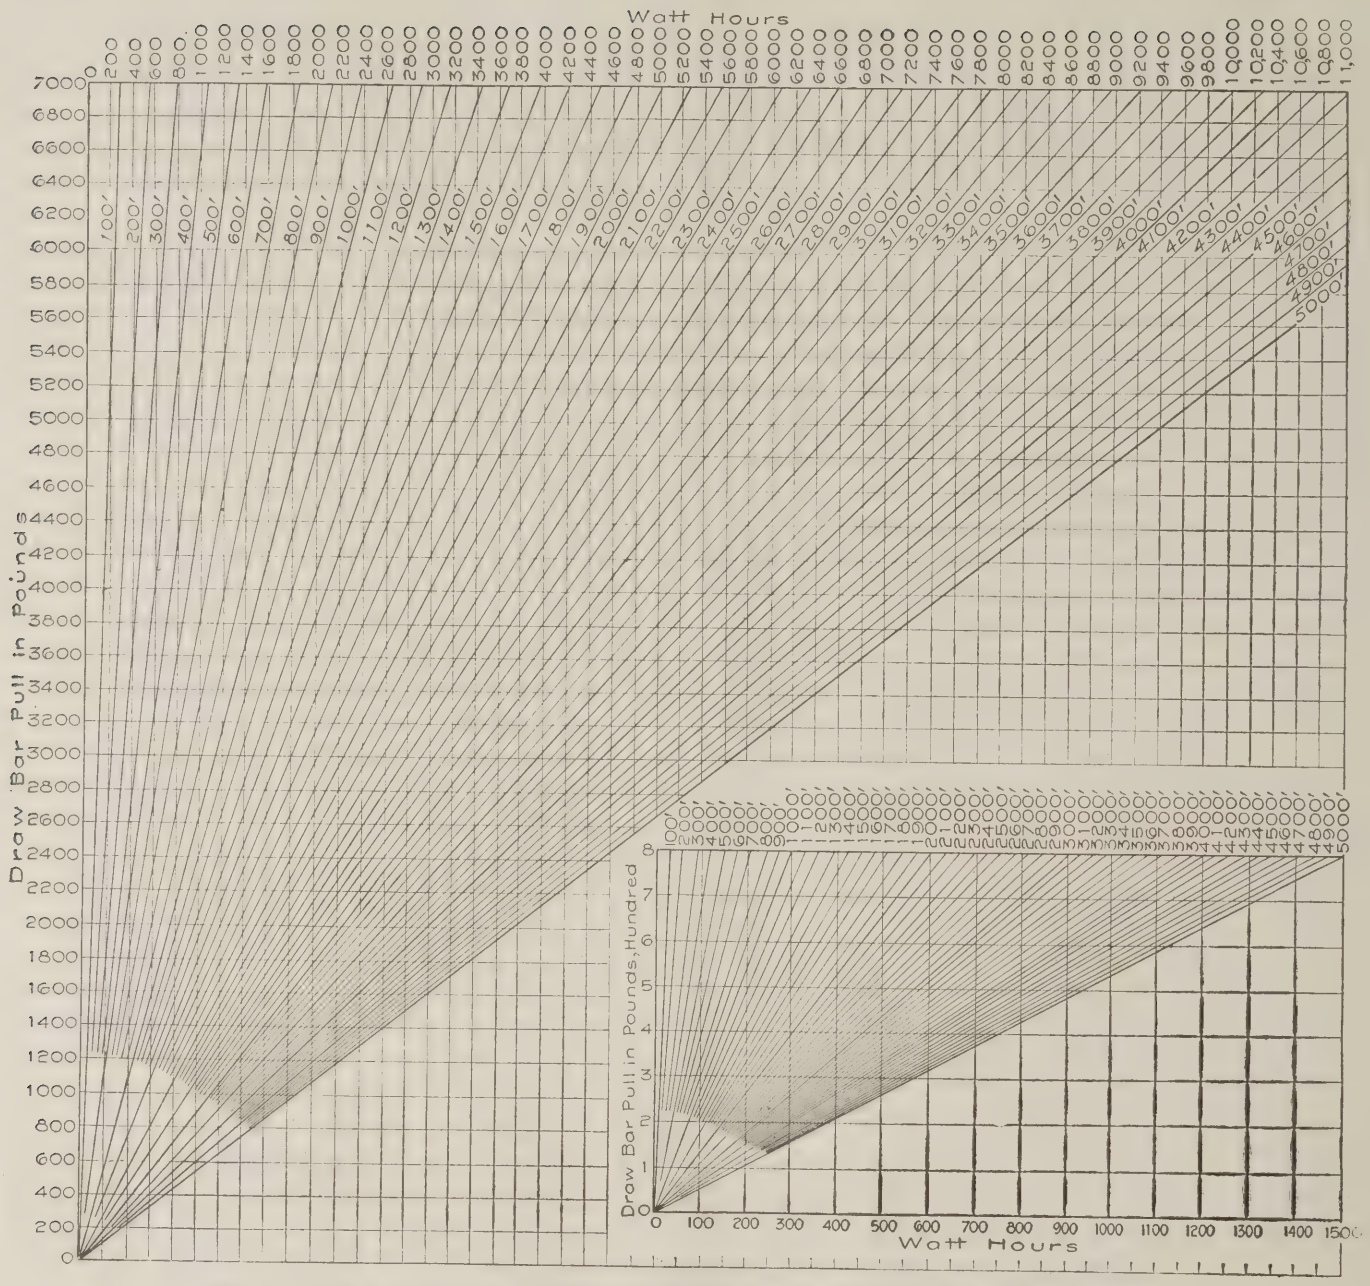

FIG. 2. THE WATT-HOUR CONSUMPTION FOR DRAWBAR PULLS AND DISTANCES

ator and on the information given him by the manufacturer. After the type of the cell has been determined, the only step necessary to settle the number of cells is to divide the total watt-hour capacity by the amperage of one cell and this quotient by the voltage of one cell. The result will be the number of cells required.

It will be noticed that no allowance has been made for any loss of power in the motor itself. The motors used in storage-battery locomotives of course are not 100 per cent. efficient, and there is also a loss between the battery and the motor and some loss within the battery itself. It is not necessary to consider these losses for two reasons. In the first place in the charging of the battery the ammeter is so arranged that a 20 per cent. overcharge is put into the battery, thus taking care of the battery loss. Secondly, the manufacturers always underrate their batteries about 25 per cent. Thus if the manufacturer's rating is used when calculating the size of the battery, this 25 per cent. will compensate any further losses. The friction losses in the locomotive are taken care of in the calculation for the drawbar pull.

The following is a calculation of the size of a locomotive and its battery, to operate over certain grades and do a certain amount of work. Let it be assumed that the locomotive will be used for gathering, and that the total distance from the sidetrack to the last room is 2500 ft. The mine cars weigh empty 2000 lb. and hold a load of 3 tons.

The track from stations 0 to 100 on the cross-entry is level, from stations 100 to 400 it has a 2 per cent. grade against the loads; from stations 400 to 600 it has a grade of 1½ per cent. in favor of the loads; from stations 600 to 1000 it has a grade of 2½ per cent. against the loads. On the butt entry from stations 0 to 300 the track has a grade of 4 per cent. in favor of the loads; from stations 300 to 500 it has a grade of 2 per cent. against the loads; from stations 500 to 700 the grade is 5 per cent. in favor of the loads; from stations 700 to 1050 the grade is 6 per cent. against the loads, and

between stations 1050 and 1500 the grade is 4 per cent. against the loads.

The rooms are 300 ft. long and are driven 1 per cent. in favor of the loads. Twenty-four men are working in a butt entry, 12 on each side, and each two men have three rooms.

The first step to determine is how long it will take the locomotive to make a round trip and how many trips it can make in a day of 9 hours under the maximum haulage conditions, which are encountered when rooms at the head of the entry are driven up 150 ft. and when the first rooms that the men are working in are practically finished. Therefore the average length of the rooms that the locomotive will have to traverse is about 225 ft. As 12 men will be working in pairs on each side of the butt entry, the locomotive will take six

TABLE III. CALCULATION OF TIME REQUIRED TO MAKE ROUND TRIP

	Minutes	Seconds
Couple motor to trip of 6 empties	1	30
Running time, sta. 0 to 100 at 4 miles per hour		17

Total running time				31 min. 39 sec.

cars to a trip. Table III shows how to calculate the time required by the locomotive to make the round trip.

The track condition will be considered to be medium and the rolling friction to be 30 lb. per ton of train weight. It will be noticed that on a part of the 6 per cent. grade the heaviest load will be hauled—that is, six loaded cars weighing 48,000 lb. It will be assumed that the purchaser will prefer a locomotive of the two-motor, double-truck type with the drive on all four wheels of each truck, and that it will have steel wheels. By referring to Table I it will be found that this type of machine has a ratio of 30 per cent. between the drawbar pull and the weight.

Referring to Table II, under the column for a 6 per cent. grade and 30 lb. of friction per ton, the nearest figure to the maximum of 24-ton load is found to show an 8-ton locomotive with a tractive effort equal to 30 per cent. of its weight. Such a locomotive, therefore, will handle the load over the given grade and is of the proper type.

Having determined the weight of locomotive necessary, the next step is to find the size of the battery required to furnish the power. First the amount of power required on each grade will have to be determined. In order to learn this the drawbar pull on each grade has to be found. Then knowing the length of the grade, the watt-hour consumption can be obtained from Fig. 2. The best way is to tabulate the figures obtained as shown in Table IV.

The total number of watts required to make a round trip is thus equal to the sum of the watt-hours thus shown, or 1929.

TABLE IV. METHOD OF TABULATING DATA

Station	Distance Ft.	Load, Lb.	Grade, Per Cent.	Drawbar Pull, Lb.		Watt-hours
1470–1335	135	L 16,000 / T 8,000	4	720 / 440	1,160	58
1335–2200	135	L 16,000 / T 16,000	4	720 / 880	1,600	80
1200–1065	135	L 16,000 / T 24,000	4	720 / 1,320	2,040	100
1065–1050	15	L 16,000 / T 32,000	4	720 / 1,760	2,480	14
1050–930	120	L 16,000 / T 32,000	6	1,040 / 2,240	3,280	148
9930–795	135	L 16,000 / T 40,000	6	1,040 / 3,000	4,040	210
795–700	95	L 16,000 / T 48,000	6	1,040 / 3,600	4,640	170
700–500	200	L 16,000 / T 48,000	5			
500–300	200	L 16,000 / T 48,000	2	400 / 1,680	2,080	158
300–000	300	L 16,000 / T 48,000	4			
1000–600	400	L 16,000 / T 48,000	2½	480 / 2,000	2,480	376
600–400	200	L 16,000 / T 48,000	1½			
400–100	300	L 16,000 / T 48,000	2	400 / 1,680	2,080	237
100–000	100	L 16,000 / T 48,000	Level	80 / 720	800	30
000–100	100	L 16,000 / T 12,000	Level	80 / 180	260	11
100–400	300	L 16,000 / T 12,000				
400–600	200	L 16,000 / T 12,000	1½	320 / 420	740	53
600–1000	40	L 16,000 / T 12,000	2½			
000–300	300	L 16,000 / T 12,000	4	720 / 660	1,380	156
300–500	200	L 16,000 / T 48,000	2			
500–700	200	L 16,000 / T 12,000	5	880 / 780	1,660	128

The remainder of the grades for the empty cars are in their favor.

As the motor has to go in the rooms 12 times to make up a trip and distribute the empties, we get:

Distance, Ft.	Grade, Per Cent	Load, Lb.	Drawbar Pull, Lb.		Watt-hours
225	1	L 16,000 / T 2,000	240 / 50	290	23
225	Level	L 16,000 / T 8,000	80 / 120	220	19
					42×12

Equals 504 total watt-hours

This gives a grand total of 2433 watt-hours for a complete round trip, and as the locomotive will make 17 round trips in 9 hr., the battery will have to furnish 41,361 watt-hours. It may be safely assumed that the cells will be of 500 ampere-hour and the voltage of the battery will be 82. Allowing 2.2 volts per cell, the total number of cells required will be 38. As this number is not convenient for the locomotive manufacturers, they will probably use either 42 or 44 cells. This number will obviously give a capacity and voltage slightly above bare requirements, which is not objectionable.

Minecdotes

On Center and Backfired

The new motorman was expressing his opinion of his locomotive. He said it reminded him of both a steam engine and a flivver.

"How do you figure that out?" asked "Curly," our oldest motorman.

"Well," said the new man, "the darn thing got on center this morning, and when I went to push it off it backfired and knocked me down. Now, then, if that is not like a steam engine and a flivver, what is?"

"On center and backfired? What you trying to give us"?

"I'm not trying to give you anything. I mean just what I said. It happened over at the South, where those boards are alongside the rails. I was coming out of there real slow, with no cars on, and the fire was flashing something fierce from the wheels and the rails. The locomotive acted just like the spark was missing in some of the cylinders. We were coming along in jerks, and then it stopped dead. I tried to start it several times, but nothing doing. I concluded the darn thing was on center. I put the controller lever on the first point, got off, and started to shove on the thing so as to move it off center. The blame thing must have backfired, for it knocked me a winding. It sure hit me a good one, and I saw all kinds of fireworks. It certainly hit me some wallop."

"Oh, so that is what you call on center," said the others after they had had a good laugh. "Why Simple Simon had nothing on you. What your trouble was, was that the locomotive wheels had so much dirt and sand between them and the rails that they were practically insulated from the return. When you put the controller on the first point you simply charged the whole works, the same as the trolley line. Then you got off to push on the machine and probably put your foot against the rail and your hands on the locomotive. Sure thing you saw fireworks and thought a mule had kicked you! Better be more careful next time, as you are liable to get on center and the backfire will knock you out for keeps. We have all had the same experience at one time or another, and experience is a wonderful teacher. Even if it is at times a little rough on a fellow, it generally leaves an impression that is not soon forgotten."

More Profitable for Whom?

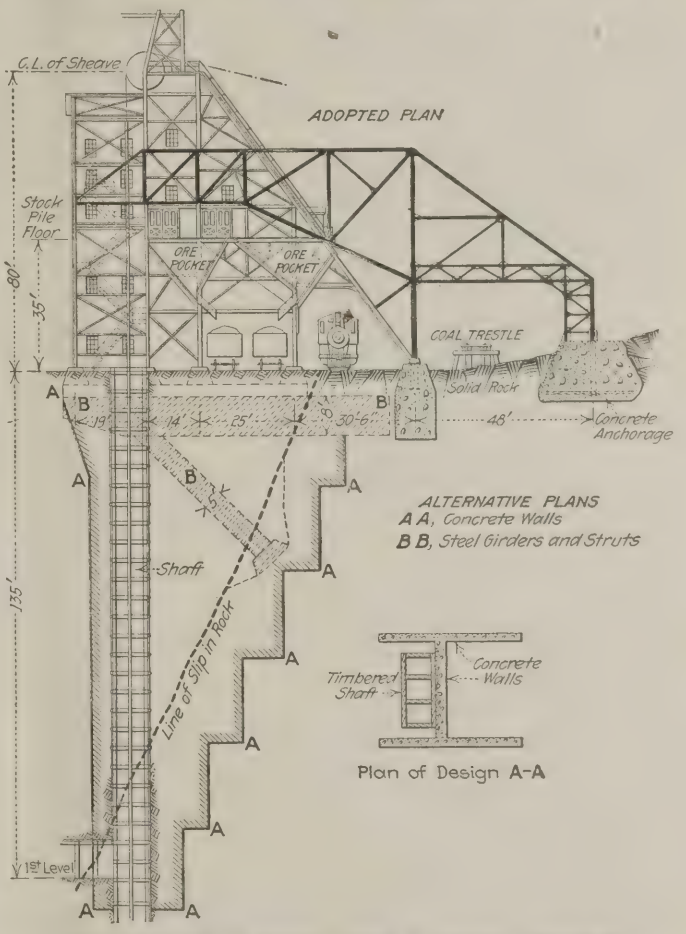
Steel Cantilevers Support Headframe

SUPPORTING the headframe over a mine shaft by cantilever trusses was the expedient resorted to at the "A" shaft of the Pioneer mine of the Oliver Iron Mining Co. at Ely, Minn., because of unstable ground.

This shaft was sunk in the early '90s, and was then equipped with a timber-frame shafthouse. It had been impossible to explore the ground in advance to such an extent as to determine thoroughly the nature of the underlying rock, but no change of alignment was experienced until 1900, when a slip in the formation was noticed about 135 ft. below the collar of the shaft. The depth at that time was 1110 ft. The alignment was maintained without difficulty, however, by trimming the timbers and occasionally replacing a shaft set.

A steel headframe was built in 1909, up to which time the settlement at the surface had not been serious. In this structure the rear columns were placed 70 ft. from the shaft and were supported on independent concrete piers founded in good solid ground. The front columns and ore-pocket columns were supported on a concrete base, 50 x 65 ft. and 3 ft. thick, reinforced at top and bottom with steel rods, so that when settlement occurred the entire front portion would move uniformly, thus causing no undue stress in the steel members.

The bases of the rear columns were provided with a hinged joint. The bases of the front columns and ore-pocket columns were fitted with brackets so that jack-screws could be placed under these to raise the columns and thus take up any settlement of the ground. From 1909 to 1912 the settlement due to the slip in the shaft amounted to 9 in., which was taken up by jacking the front columns of the shaft at different times and putting blocking under the bases.



Movement of the ground became much more serious in 1912, and it was apparently unsafe to continue mining operations near the shaft without making provision to support the shafthouse. Consideration was given to three different methods for supporting the shafthouse and pockets.

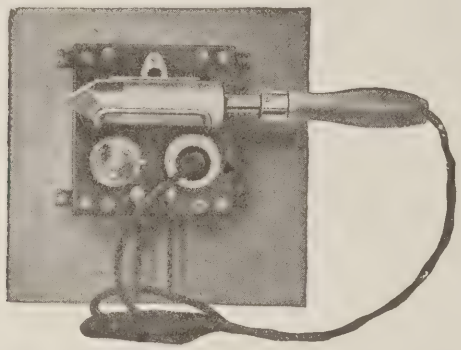
The first plan was to excavate the entire portion between the line of slip and the shaft and construct a vertical concrete wall with two wings, all founded on solid rock. This would extend from the first level in the shaft, 135 ft. below the collar, to the under side of the reinforced-concrete base supporting the front portion of the shafthouse, as shown by dotted lines *A*—*A* in the drawing. The wall would carry the entire load of the foundations, tracks, cars, front portion of shafthouse and ore in shipping pockets, and would support the rear portion of the mine shaft from first level to surface.

The second plan was to excavate beneath the reinforced-concrete base and place two horizontal steel girders under it, as shown by dotted lines *B*—*B*. The rear ends of the girders would be anchored on good ground back of the slip, and the ends over the shaft would be supported by structural steel struts or columns placed at an angle of 45 deg. and seated on solid rock.

The third plan, which was adopted, was to construct a steel cantilever support, having its footings on permanent ground back of the slip. This carries the portion of the shafthouse above the stockpile trestle, which consists of skip dumps and headsheaves. All main columns of the shafthouse were disconnected at splices at the stockpile floor elevation, except the rear batter-brace columns, which have a firm footing. The cantilever support thus maintains the headsheaves and skip dumps in permanent position, and the front part of the shafthouse, including the stockpile floor and shipping pockets, now cut loose from the upper portion, will be kept in position by jacking up and blocking the column bases as may be required by ground settlement.

Adoption of this plan was based upon the fact that its first cost was the lowest, and that this structure was above ground, where it could be erected readily and inspected easily. As the rear columns of the cantilever support are on solid rock and have an uplift, the pier excavation was made in the shape of a prismoid and the concrete was poured without the use of forms. The concrete pier was made large enough for its weight to balance the uplift due to the weight of the shafthouse portion; the bond of the prismoid in the solid rock is an additional safety factor.

HEADFRAME IS HUNG FROM A GIANT BRACKET



As the mine shaft is constructed of timber sets and is considerably larger than the skips and cages, there is sufficient room for lining the timber guides without retimbering or enlarging the shaft. The cantilever support has now been in service for practically five years, and has kept the upper part of the shafthouse in accurate alignment. The lower portion has settled two feet, which has been taken care of by jacking up and blocking the front column.—*Engineering News-Record.*

NEW APPARATUS AND EQUIPMENT

Automatic Rack for Electric Soldering Irons

Electric soldering irons that are allowed to lie on a bench or other convenient place when temporarily not in use gather dirt and become a hazard. Often the tip will be overheated, necessitating refiling; the heating unit may burn out; the hot iron may set fire to the bench or other material. If the current is turned "off," the iron cools down to such a degree that considerable delay is caused when the tool is again wanted.

To overcome these objectionable features the Cutler-Hammer Manufacturing Co., of Milwaukee and New

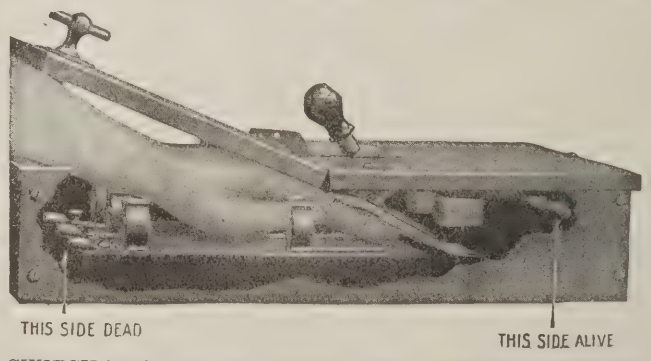
PANEL FOR MOUNTING ON WALL, SHOWING METHOD OF SUPPORTING SOLDERING IRON

York, has recently developed an automatic soldering-iron rack and control panel which decreases the amount of current taken by the iron when it is placed on the rack. This keeps the iron from overheating, prevents burnouts and saves current. Furthermore, it encourages orderliness by providing a convenient connection point and support for the iron.

The rack consists of a small slate panel arranged for wall mounting and carrying a support for the iron which acts on the principle of the telephone receiver hook. When the iron rests on the support, or hook, it bears it down and resistance, which is mounted on the back of the panel, is inserted in circuit with the iron. The current is reduced and the temperature held at a safe value, but ready for service and full current as soon as the iron is lifted from the hook.

Taking the weight from the hook disconnects the resistance from the soldering-iron circuit and allows full current to flow. Below the hook, on the same panel, a push-button snap switch is mounted together with a "standard" receptacle, to which the plug of the soldering-iron cord is connected. This little panel, therefore, is a complete switchboard which may be mounted on the wall or machine within reach of the workman. When not in use, and at night, the switch is snapped "off," which completely opens the circuit to the iron.

These automatic racks are designed for use with Cutler-Hammer soldering irons, but they are so constructed that they may be used just as well with other similar types of soldering irons.



Auto-Lock Safety Switch

In many mines, steel mills, factories and similar industries where most of the workmen have little knowledge of electricity it is desirable to use switches having no live parts exposed or accessible in the ordinary operation of the switches or when replacing fuses.

This is fully accomplished in the Krantz auto-lock switch, marketed by the Westinghouse Electric and Manufacturing Co., which is intended for use on main circuits or wherever an ordinary knife-switch is applied. The switching parts and fuses are inclosed in a steel box, the cover of which is in two parts, one being screwed on to form a permanent covering for that end of the box containing the switch, and the other part being hinged so as to swing back and permit the renewal of fuses, which are located in this portion of the box.

An ingenious latching mechanism makes it impossible to open the cover without first throwing the switch to the "off" position and rendering all fuses and other accessible parts dead. Thus fuses may be replaced at any time with absolute safety. As long as the door of the case is open, the switch contacts cannot be closed.

By using a padlock, the switch handle can be locked in the "off" position, making it impossible for any-

SWITCH MUST BE PLACED IN "OFF" POSITION BEFORE COVER CAN BE OPENED

one to close the switch, except the person holding the key to the padlock. By using another padlock, the cover may be locked shut, so that the fuses cannot be tampered with. Either of these padlocks can be used independently of the other, so that the switch cover can be locked shut with the switch either "on" or "off," or the switch can be locked in the "off" position with the cover either locked or open.

Electrical contact is made by means of a laminated-spring copper brush, double-ended with auxiliary arcing contacts at each end. The outer leaves of the brush are bronze to provide additional spring pressure.

The stationary contacts are of hard-drawn copper and are mounted on slate bases, one of which in the fused end carries one of the fuse clips while the other

forms the terminal block for the incoming line and is mounted under the stationary portion of the cover.

The operating mechanism, of the toggle type, is galvanized steel and is attached to the under side of the stationary end of the cover. This mechanism can easily be removed for inspection by taking out several screws.

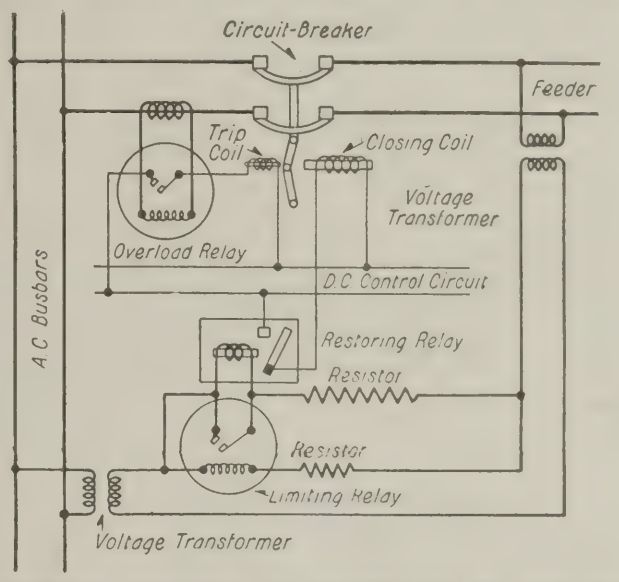
In closing, the pressure between the contacts causes the laminations of the brush to spread apart, giving it a wiping or self-cleaning action. The double-ended brushes provide a double break, dividing the arc between the two ends, each of which is provided with a separate arcing tip.

In the closed position the switch is held in positive contact by throwing a toggle over the center point. A spring provides a quick-break for opening, the mechanism being independent of the operating handle.

These switches are supplied for 250-, 500- and 600-volt circuits, for either alternating- or direct-current service, and in capacities up to 2000 amperes.

The safety features of this switch have been recognized by the American Museum of Safety, which has awarded it a gold medal and special mention.

Service-Restoring Relay System



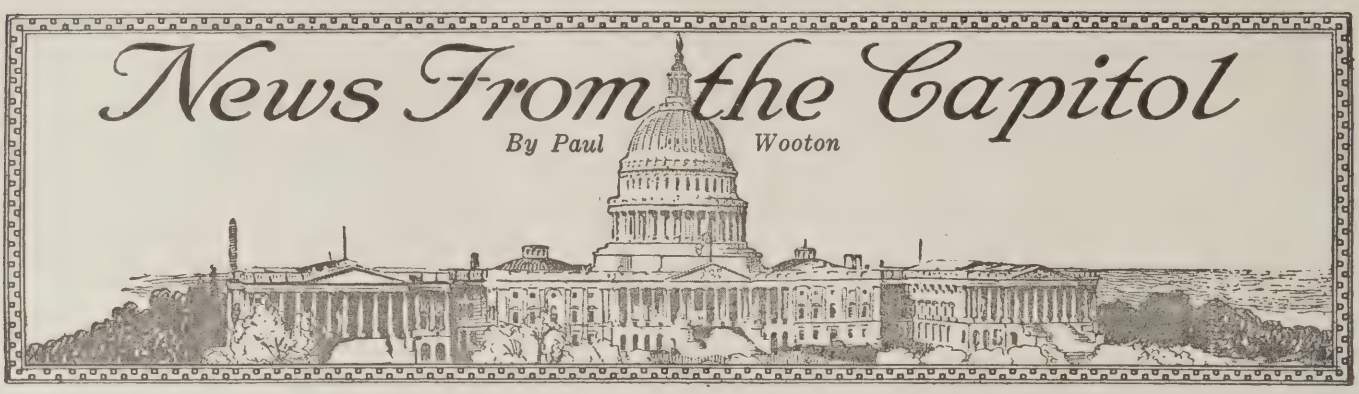
A new service-restoring relay system has been tried out for a number of months on the lines of several central station companies of considerable size, and the reports received have been satisfactory. The system minimizes interruptions caused by transient short circuits, which clear themselves as soon as the circuit breaker has been opened, thus permitting the feeders to be immediately put back into service. If the circuit breaker is reclosed automatically within a second after the transient trouble has occurred, the service will be restored in time to prevent induction motors from stalling.

The Westinghouse service-restoring relay system has been developed to perform this operation within the shortest possible time and thus reduce all disturbances to a minimum. This greatly improves the lighting service. Should a permanent defect occur, the system will allow the breaker to remain open until the defect is cleared.

A schematic diagram of connections is shown in the accompanying illustration. Any type of overload relay may be employed to trip the circuit breaker. A voltage transformer on the feeder line outside the circuit breaker is connected so that its potential opposes that of another voltage transformer connected to the busbars. The restoring relay, which is similar to a magnet switch, is connected in series with these two voltage transformers. Before a short circuit occurs, both voltage transformers are subjected to the same condition so that no current will flow through the restoring relay; but when a short circuit develops and the circuit breaker has been opened by the overload relay, current will be forced by the busbar transformer into the feeder transformer through the restoring relay. The restoring relay will then close its contacts, which in turn will close the circuit breaker.

In case of a permanent defect on the feeder line, the restoring relay would continue to open and close the circuit breaker indefinitely. To prevent this, a limiting relay, similar to the Westinghouse type CV overvoltage relay, but equipped with weaker spring and heavier damping magnets so that its action is sluggish, is connected in such a manner that while the circuit breaker is open it is subjected to the same difference of potential that is operating the restoring relay. Every time the circuit breaker opens, the limiting-relay contacts begin to close and, due to the heavy damping, they do not return to the starting point immediately after the circuit breaker is closed. After the circuit breaker has opened and closed a predetermined number of times, this relay closes its contacts, thus short-circuiting the restoring relay and preventing further operation.

When this system is installed at substations having no attendant, it is often found advisable to have an indicating device that will show when the service has been



SCHEMATIC DIAGRAM OF CONNECTIONS OF SERVICE-RESTORING RELAY SYSTEM

momentarily interrupted. For this purpose, a graphic ammeter is placed in the direct-current control circuit of the circuit breaker. This will indicate whenever the breaker has been closed by automatic means.

A special control switch is used, which contains one dragging contact so arranged that when the circuit breaker is tripped manually the switch automatically opens the circuit between the two voltage transformers.

The service-restoring relay outfit is a valuable addition to the protective equipment of all central stations, and should be especially useful now. This relay decreases power interruptions and thus economizes the time of switchboard and other station attendants, or in some cases releases some of them for other duties.

Hydrocarbons are decomposed or cracked by heat. Carbon and hydrogen are the ultimate products when cracking is carried to the end. The decomposition is a complicated process, the exact mechanism of which is not known, but it is governed by the laws of physical chemistry. Equilibrium conditions determine the extent to which cracking occurs, and the values of the equilibrium constant depend, among other factors, upon the temperature and pressure. High temperature favors cracking because most of the reactions take place with absorption of heat.—*Bureau of Mines Bulletin No. 135.*

Operators Contradict McAdoo

Issue has been taken with Director General McAdoo as a result of some of his statements on the supply of cars for coal mines, made in his report to the President. Among those challenging the purport of his report is the National Coal Association. Mr. McAdoo's entire statement as to the coal movement reads as follows:

Just at present strenuous efforts are being made to speed up the movement of coal so as to preclude the recurrence of the distressing experience of last year. In both the production and transportation of coal 1917 was a record year. Including bituminous, lignite and anthracite the production was 650,000,000 tons. Of this some 11,563,056 cars, containing about 558,000,000 tons, were transported by the railways. The balance was either consumed or converted into coke at the mines or near by. During the bad weather in January, 1918, when the railroads were practically at a standstill, there was a reduction of 79,131 in the number of cars of coal loaded and moved as compared with the year 1917. Notwithstanding the continued bad weather in February, 1918, the railroads got on their feet and increased over February, 1918, 31,250 carloads of coal. In March the increase was 46,613; in April, 73,408; in May, 84,998; in June, 88,840; and for the first four weeks of July, 113,198 cars. It will be seen, therefore, that for the last six months the increase in coal carried by the railways has been 437,976 cars of coal—equal to about 21,998,800 tons.

One of the great advantages of governmental control is that the transportation facilities of the country can be concentrated upon the quick performance of an urgent duty. The energies of the Railroad Administration are now being largely devoted to moving the coal mined as rapidly as the Fuel Administration can deliver it.

Of late cars have frequently been supplied to the coal mines more rapidly than they have been able to load them and it is probable that adequate transportation for the fuel requirements of the Nation will be available provided the coal production during the warm weather can be maintained at a point that will fully employ the cars requisitioned. The country has been led to believe that coal production is limited entirely by transportation and that any shortage is due to the railroads. This is erroneous. The maintenance of an adequate coal supply depends in the first instance upon production which in turn is restricted by shortages of labor and other causes aside from transportation.

The situation, as viewed by the National Coal Association, is very different. Its statement is as follows:

So far as the car supply for bituminous caol loading is concerned, Mr. McAdoo apparently has not been informed fully as to all the facts in the case. It is true that in certain sections of the country the supply of empty cars furnished bituminous coal mines has shown marked improvement during the summer months; and the industry as a whole also has enjoyed an increased car supply. This supply, however, is by no means adequate when the whole industry is considered, as the government's own figures show.

These figures, made public by the United States Geological Survey, which keeps a careful record of coal production and the causes curtailing such production, show that during the latest week covered by returns from producing fields, that of Aug. 24, car shortage cut production no less than 1,530,000 tons of bituminous coal. In four fields alone—Southern Ohio; Somerset County, Pennsylvania; Fairmont, W. Va., and the high volatile fields of southern West Virginia—the bituminous coal mines lost 750,000 tons during the week because the railroads failed to furnish cars to load this tonnage. Director General McAdoo certainly did not have these fields in mind when he reported that "cars have frequently been supplied to the mines more rapidly than they have been able to load them."

One coal-producing company in West Virginia, whose output of byproduct coal is made into coke and in that form is used in the production of steel, lost 100,000 tons during the month of August because cars were not furnished to load and haul this tonnage. This loss was directly reflected in the curtailment of steel intended for ships at a time when the output of steel plants was being reduced because of their inability to obtain sufficient fuel. Another company in the gas coal fields of western Pennsylvania ran part time and lost 170,000 tons production of coal because of the inadequate car supply.

Shortage of railroad cars at the bituminous coal mines of the country has curtailed production not less than 82,000,000 tons since Jan. 1 last, and stands as the dominating factor of all causes of curtailment. Much of this huge production lost to the country because the railroads did not furnish the coal mines sufficient cars occurred during the months of January, February and March, when the railroads were recovering from the worst congestion in their history and from the effects of unprecedented storms, but not all.

Car shortage cut bituminous coal production 1,934,000 tons during the week ending Aug. 17; 1,559,000 tons during the week ending Aug. 10; and 1,145,000 tons during the week ending Aug. 3. These figures do not support a claim that the coal mines are receiving more cars than they can load, even recently.

The production of bitumnious coal from Jan. 1 to Aug. 24 inclusive, totaled 384,000,000 tons. The mines that produced this coal were capable of producing 522,000,000 tons under full time output. The total production lost from all causes was therefore 138,000,000 tons—far more than enough to afford a guarantee against a fuel shortage. Here are the reasons why this 138,000,000 tons were lost:

Because of car shortage, 82,000,000 tons; because of labor shortage and strikes, 22,750,000 tons; because of mechanical disabilities and unavoidable shutdowns at the mines, 19,750,000 tons; because of no market (chiefly in southwestern states) 4,000,000 tons; all other causes, 9,500,000 tons.

It will thus be seen that car shortage, the dominant factor curtailing bituminous coal production during the year, was responsible for approximately 60 per cent. of the total production lost from all causes.

These figures are not guesswork. They are the government's own figures, as published by the Geological Survey. They show conclusively just what did limit coal production.

Operators Advised to Obtain Deferred Classification for Employees

The War Department has provided the necessary machinery for the protection of essential industries such as mining from the indiscriminate operation of the draft, and depends upon the companies and individuals to protect their industries by taking special care to see that skilled labor which cannot be replaced receives the proper industrial deferred classification. Mining organizations producing necessary war minerals should consider it a patriotic duty to attend actively to this matter at once and to take up with their local boards the classification in the draft which their keymen should receive, Van H. Manning, director of the Bureau of Mines, declares.

The Army desires to have every man who can be replaced put into a classification where he will be ready to carry a gun as soon as called for, but does not wish to take men who would be more useful for war purposes where they are. Should those engaged in the conduct of essential war mines not carry out this duty promptly, the War Department may naturally hesitate to furlough back men from the army in cases where the companies have neglected to ask for the proper deferred classification for their men as provided for under the selective draft regulations.

Machinery has also been created whereby in some instances the keymen in essential industries who have failed for any reason to receive industrial deferred classification may still be returned to their work by the Adjutant General of the Army after their arrival at camp. Under this arrangement, the different departments and bureaus representing certain industries may designate a certifying officer, who may recommend to the Adjutant General that the soldier in question be granted an indefinite furlough without pay and ordered to report to the industry where his services are needed.

Chief Coke Inspector Appointed

R. C. Glazier, of Johnstown, Penn., has been appointed chief coke inspector for the Fuel Administration. It is the intention to centralize the work being done for the improvement in the quality of coke. Mr. Glazier will also concern himself with the matter of conservation of fuel and increase of production.

Coke Company To Make Large Refund

The Fuel Administration's statement concerning the $80,000 refund which it has required the Consolidated Coke Co., of Pittsburgh, Penn., to make, is as follows:

A refund of a sum approximating $80,000 was arranged Sept. 7 by the United States Fuel Administration between the Consolidated Coke Co., of Pittsburgh, as party of the first part, and the Steel Company of Canada, of Hamilton, Ontario, and the Thomas Iron Co., of Hokendauqua, Penn., as parties of the second part. The refund came as the outcome of the delivery of inferior coke to the two companies of the second part.

The Consolidated Coke Co. had contracts providing for the delivery of coke made from washed coal to the blast furnaces of the other two companies. Last November the Consolidated Coke Co. washery broke down and shortly thereafter burned, rendering the producers unable to ship coke of the quality contracted. Also, in order to secure maximum output, the coke company had installed coke-drawing machines which enabled them to maintain the regular output of coke, but, as appeared, reacted unfavorably on the quality of coke produced.

It was clearly evident to the Fuel Administration that both the iron companies had been seriously damaged, not only by increased fuel consumption but also had been unable to meet the requirements for metal of their respective governments.

The Consolidated Coke Co. agreed to pay to each of the other companies a sum amounting to $1 per ton for each ton of coke shipped to them from June 1 to Aug. 15. Also it agreed to rebuild its washery at the earliest possible date.

The sum involved, while large, in no way represents the loss sustained by the furnace companies and, of course, the national loss due to the curtailed tonnage of iron and steel cannot be calculated in dollars and cents. It is the belief of the Administration that the exercise of its power to maintain the standard of quality of coke, by control of prices, will result in more vigorous efforts on the part of all coke producers to use their properties to the utmost extent to aid in the effective prosecution of the war.

Work-or-Fight Order Has No Application in Coal Mining Industry

The "work-or-fight" order does not apply to any employee of a coal-mining company, General Crowder, the Provost Marshal General, has informed the National Coal Association. Where local boards notify clerks or any other employee of a coal-producing company that they must seek other work, the fact is to be communicated at once to the Provost Marshal General.

Criticized for Attitude on New Mines

Considerable criticism is being aimed at J. G. Jones, of the Fuel Administration, and his committee charged with the licensing of new mines. It is contended by some that the few permits which are being granted are threatening the future coal supply. Mr. Jones admits that a change of policy may be necessary if the war should be greatly prolonged, but for the present he is fully determined to allow no new mines to open which will influence production in mines that are already producing.

With the steel situation in its present shape, Mr. Jones declares that no machinery can be spared for mines not in a position to use the equipment for immediate production. There are, of course, some permits being granted where exceptional conditions make large production possible in the near future.

In those sections of the country where the railroads are not congested, and where idle machinery, in many cases, can be rigged up to do the work, the same stringency is not being exercised as is the case in the coal fields of the East and of the Middle West.

The cost of handling cars of coal diverted from their original destinations to relieve an emergency may be added to the regular freight charges, the Fuel Administration has ruled.

A service flag containing 50 stars was hoisted over the Fuel Administration building at noon Sept. 6. Dr. Garfield, who has two sons in the service, delivered a brief address to nearly 1000 of the employees of the administration.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

We reproduce in the panel on this page the remarks of P. B. Noyes, director of the Bureau of Conservation, of the United States Fuel Administration. Against it and almost around it we write the answer of the anthracite mine workers. Apparently they are willing to accept the awful sacrifice of life and limb of which Mr. Noyes speaks. We shall face the foe partly armed, partly munitioned, and merely because a wage readjustment is sought by the anthracite mine workers, an adjustment that is in violation of their pledge given only at the close of last year. Though they had a contract at that time a readjustment was made in their wages, yet now they are striking again, despite the fact that their arguments are being considered by the Department of Labor and the Fuel Administration.

WE CANNOT fill Pershing's orders in full because the United States cannot make sufficient steel this winter. A shortage in steel results almost entirely from lack of coal. Keep this in mind and then look forward to the events of the coming spring. We shall have the drive. We shall succeed in it, but some time in February or March, or whenever the time has come, General Pershing will sit down with a pencil in hand and will figure up the exact deficit in the filling of his orders for munitions. With military formulas now well recognized, he will figure in place of those munitions how many extra men must be put into the battle to be killed. This is no fanciful statement. It is now possible to treat, in any aggressive movement, the question of munitions or of casualties as interchangeable quantities. So many thousand American youths must be thrown into the hopper for every thousand tons of munitions which are short.—P. B. Noyes, Conservation Division, United States Fuel Administration, addressing engineers at Cincinnati, Ohio.

Are the mine workers of the anthracite region willing to take on themselves the blood of the slain by striking at this time in violation of their pledge? It seems as if they are. On Sept. 8 four collieries of the Delaware & Hudson Co. in the Wyoming valley were closed down by a strike of motor runners, drivers and doortenders, and at two others the same classes of men were, at that date, threatening to go on strike. The four mines when operating employ 1500 men, the other two employ 1000 more, so 2500 men will be involved if the strike spreads.

The motor runners want an advance of 15c. per hour; they now receive 35c. The drivers get 24c. and want 35c., while the doortenders, who are paid 12c., are now asking 24c.

The miners at one of the Panther Valley operations have gone on strike for an increase while the men in the Hazleton region are pressing for extra pay for overtime and have inserted paid advertisements in the local papers telling the men at certain mines to be careful not to do Sunday work. The union is counseling patience and the fulfilling of contracts, but the men are wrath with the union, and condemn it more heartily than they do their employers.

The strike for free transportation at the Sandy Run colliery of M. S. Kemmerco and Co. still continues. When the men struck the company announced a shutdown for repairs. This is probably not altogether a move of strategy. It may merely show that the company, anxious to make repairs, thinks the present time favorable. The mine has had some severe squeezes in recent years, and repairs are possibly quite necessary. The men, though dispossessed, are not idle. The labor scouts of the companies operating in the neighborhood quickly lighted on these men and they are busily mining coal in nearby workings.

The northern Pennsylvania coal fields in the neighborhood of Blossburg, Tioga County, are still busily at work though few, if any, sections of Pennsylvania have mined bituminous coal longer than Blossburg and the vicinity. The Blossburg employees of the Morris Run Coal Mining Co. and O'Donnell Brothers Co. have asked that a work train be run from Blossburg to the plants of these companies.

The mountaineers of West Virginia and Kentucky are justifying the motto of the first state—"Montani semper liberi" (the hill country people are always free), by strenuous efforts to aid America in her struggle for liberty and justice. They have the most intense kind of patriotism. E. E. White, president of the E. E. White Coal Co., which operates in the hill country surrounding the Virginian Ry., pays a high compliment to the miners of his district and to the patriotic attitude of the people in general. He has been appointed production manager in the New River and Winding Gulf fields and seems to find great pleasure in the work, owing to the support given the movement by the workmen everywhere. White is not the kind of man to go round with a grievance. He sees the big things, publishes them, and big things spring up by the spreading of the seed.

Some people plant blame and discouragement and wonder that their row grows such spindling corn. After Mr. White had visited the many mines in his care he described his impressions thus: "In traveling through my district I saw miners wearied by a long day's work going back into the mine to produce more coal on the night shift. A desire to do their bit has caused the farmers to go into the mine at night and load coal. As one farmer expressed it, 'I raise wheat during the day and load coal at night to aid our boys in France.' A preacher and his congregation volunteered one night last week to load 100 tons. A worn-out miner has written saying, 'I have finished my mining days, but I'm going to pay some one to do a day's work for me.'" Mr. White concludes by asking, "In such an atmosphere as this do you think there is any room for a slacker to exist?" There's good blood in the "sagers" and good blood is bound to tell.

But the mountaineers look askance at your strolling players and mountebanks. A carnival company operating near one of the big coal mines in southeastern Kentucky interfered with production. It was summoned before the Harlan County Council of Defense, with Judge Onthank presiding. When it was testified that the production of the district had fallen by reason of the operations of the carnival company, the "attraction" was ordered to move into another district. It was found that there were two draft evaders in the troupe, one a British subject and the other a man from Missouri. Both were held. Triflers are not wanted where men are mining coal for the soldiers at the front.

At Jackson, Breathitt County, Kentucky, R. T. Gunn, the vice president of the Riverside Coal Co., has put the matter to the men in this way: "During July the Riverside Coal Co. has killed more Huns than in any months in its existence, and in August it will kill more than in July." Mr. Gunn declares that he's surely fully justified in his

statement, for all his coal goes for war work. For several months practically the entire output of the mine was shipped to Wright Brothers' aëroplane works. The output now largely goes to a plant making aëroplane parts and to a utilities company.

A Kentuckian Advocates Bonuses

Writing, as he says, "with some misgivings," a Kentucky general manager unburdens himself on the subject of bonuses as follows: "Bonuses are a great stimulus to production, and I cannot understand the attitude toward them taken by the United Mine Workers of America, much less can I fathom the reasons which have caused the Federal Fuel Administration to give support to the hue and cry against the bonus. I would like to see a discussion of the subject in your journal.

"I can readily see how the miners' union may object to a low and inadequate wage being supplemented by a bonus when it might be more reasonably corrected by a revising of the scale. But the objections are not equally strong when the wage paid is adequate and when the supplementary payment is not made to remove what is in the nature of an injustice. The wage advance that was recently granted satisfied the mine workers, and they were willing to mine coal under it. The bonuses were added not to satisfy the mine workers and not to bring their compensation up to a level of adequacy, but to induce them to produce more coal than in the past.

"I can not see any harm in a bonus such as granted, still I am willing to concede that a flat bonus paid on each and every ton mined, whether few or many, would cause a chaotic condition, because it would mean that every operator, by adjusting the bonus, could pay any rate he desired. This practice would completely disrupt the labor market in our industry. A bonus on coal mined in excess of a normal tonnage is vastly different. It means that more coal will be mined with a given supply of labor and that the miners will earn higher wages. If it is to be said in reply that by excessive work some of the men will do themselves an injury, the answer is that the eight-hour day and the limitations of the car turn prevent that probability.

"Let me illustrate my remarks by citing a specific case. In a certain mine with which I am familiar, it was found that the men were producing 5 tons a day, or 30 tons a week. In order to encourage them to work more regularly and energetically, thus increasing production, the owner notified the men that he would pay a bonus of 10c. per ton for all coal mined in excess of the average of 30 tons per man per week. The result was most gratifying. The average production was raised 20 per cent. In certain individual instances the increase was much greater. Some skilled miners increased their weekly production 100 per cent. This mine had never been able to operate on Saturdays because it could not induce its employees to enter the mine on the concluding day of the week, yet after the bonus payment was introduced 80 per cent. of a normal run was obtained on that much abused day. Bonuses have recently been discontinued because of the attitude of the Fuel Administration.

"Of course, we should look at the matter from all sides, that of the individual miner, the operator and the public. The first delivers more than an average tonnage and he is entitled to an exceptional price for the coal he mines in excess of the general average. It seems to me that the extra income gives him hope for better things, permits his indulging in comforts otherwise beyond the compass of his purse, opens up to him opportunities for investment and encourages him in the purchase of Liberty Bonds and War Savings Stamps. The bonus stimulates the exercise of those virtues that bring success. It is quite sound in principle and the end which it seeks is in line with the Government requirements for fuel.

"I have heard it contended that if the companies can pay bonuses they can pay higher wages. This argument is plainly unsound, for bonuses are paid out of the lower overhead costs resulting from increased production. This is especially true in this war period. Mines designed for large tonnages have overhead expenses in proportion to the output for which preparation has been made. If the output falls or fails to reach that level, the overhead expense per ton mounts to an alarming figure.

"Am I justified in believing that the miners' union desires to discourage individual effort and for this reason opposes itself to the bonus system? Is it not the purpose of the union to put all men into a straight-jacket, restricting their production to a certain figure? America should mean to the miner 'equality of opportunity and a chance to rise in the world by personal effort.' No miner should feel his wage so regulated to the average wage as to leave him no hope beyond and above his working place. Where men are disposed to earn and save capital they should be given an opportunity, and such opportunity is afforded by bonuses for increased production. Every man who is disposed to replace hand labor by brain labor should be allowed to avail himself of all the chances offering themselves to him.

"Bonuses reward the miner for the additional effort which he makes to increase the coal tonnage and help obliterate the gap in the ranks of the miners caused by the draft. The stopping of bonuses is sure to retard the production of coal at a time when the maximum supply of fuel is absolutely necessary to the success of the war."

Local Would Single Shift Gassy Mines

Claiming that the mines of the Crowsnest Field are too dangerous for continuous day and night operation, members of the Gladstone local, No. 2314, United Mine Workers of America, have petitioned the Minister of Mines of British Columbia to make the single-shift system compulsory in all the coal mines of the district. In support of their demand the local quotes the report of George S. Rice, of the United States Bureau of Mines, who made a special investigation on the Crowsnest coal area on behalf of the Provincial Government. The petition draws especial attention to his observations respecting the gas flow at mines in certain parts of the field. The coal operations of the Crowsnest region are located in what is termed, under the classification of the United Mine Workers of America, District No. 18. This district covers the mines of Eastern British Columbia and Alberta. The direct control of the Dominion Government, which is represented by Commissioner W. H. Armstrong, extends all over this district. Consequently it is probable that the request of the mine workers of the Gladstone local will go before the latter official for decision.

The document setting out the case of the mine workers begins with the assertion that the movement for single-shift operation was inaugurated solely because of the desire to secure greater safety in the mines at Coal Creek. It adds that conditions in the mines were so abnormal and so baffling to the engineering talent of the province that the Government felt compelled to obtain outside advice in order to prevent any further continuance of the appalling loss of life. George S. Rice is quoted as follows:

"On page 340 [of the Rice report] a statement is made that the gas flow from No. 1 East when the mine was idle was found to reach the astounding amount of 1,795,680 cu.ft. per day. When the mine was working 4,184,600 cu.ft. were given off, there being approximately three times as much gas flow when working as there was when the mine was idle."

Against these figures is held up, for purposes of comparison, the amount of gas used per day by the 11,000 citizens of the city of Medicine Hat, Alta., which amounts to 3,000,000 cu.ft. The document further maintains that gas-flows, blow-outs and bumps in the Crowsnest coal field "have invariably happened on the afternoon shift." This, it is contended, bears out Mr. Rice in his statement that the mines are being developed "too continuously or rapidly." The conclusions finally reached are that "such ground be only advanced at a moderate rate—say one shift in 24 hours." The mine workers say that while they cannot determine the terms of their employment, they can point out to the Government that it has a share in the responsibility for their safety and that they will be compelled to place

the onus on the Government in case a fatal accident arises out of the conditions stated.

While no exception is taken to the men's statements insofar as they have quoted Mr. Rice, it is maintained officially that, great as the gas flow is in the Crowsnest coal field and exceptional as are the conditions, the story has lost nothing in the telling. It is pointed out that conditions have materially changed since the expert from the United States made his investigation. The gas flow per 24 hours now, for instance, is 2,397,600 cu.ft. instead of the 4,187,600 cu.ft. given and it is declared that, "astounding" as these figures may appear at first blush, the conditions at No. 1 East Mine now are not nearly as dangerous as the petitioners would represent.

The safety of a mine is measured, according to the respondents, not by the gas flow so much as by the percentage of gas in the air currents. The mine officials say that looking at the situation from this viewpoint conditions will not appear so bad for while there is a gas flow in No. 1 East Mine of 1665 cu.ft. per minute there is a flow of 143,640 cu.ft. of air per minute in the main return airway. As a result, according to reliable statistics, the actual gas content of the air current is 1.16 per cent. Further it is pointed out that, among other steps taken by the Government to protect the men, is the regulation that immediately tests disclose the presence of gas measuring 2.5 per cent. or more the men in the working places affected must be withdrawn from the area so charged.

Mine Popular Despite Allegations as to Safety

There are six other mines controlled by the Crowsnest Pass Coal Co., namely, No. 1 South, No. 1 North, No. 2, No. 3, "B" North, and No. 9. With the exception of No. 1 South, which is about as gassy as No. 1 East, the gas content of the air of these mines runs between 0.04 and 1 per cent., but the coal is harder. All of these mines are now operated by single shift, or, to speak more correctly, there was but one shift in these mines in 24 hours at the time of writing and even under these conditions there were a few weeks ago, and presumably still are, idle working places. This is due, of course, to lack of labor and this shortage is considered especially serious because the colliery is understood to have orders for 8000 tons of coal a day and is able to produce approximately only 2000 tons. But it is also thought to be somewhat remarkable that No. 1 East Mine, with which the petition deals specifically, is the only mine which it is possible to work on double shift; in other words, that it is the most popular mine of the Crowsnest district, despite the allegations made as to its safety. The question has been asked: Is its popularity due to its soft, easily-mined coal? Of course the easier the coal is to work the more can be mined and the higher the wages. The question is finally put thus: If the men are so eager to work in this mine that they fill up both shifts and will not fill a single shift at the other mines, would they be willing to be deprived of the opportunity of working at this mine if the Government should accept the union's suggestion? Obviously many men will have to be displaced if No. 1 East is to be run single shift as suggested.

Watkins' Letter to His Mine Foremen

From T. H. Watkins, the president of the Pennsylvania Coal and Coke Corporation, the mine foremen of that company have received a letter, urging them to do their part in the production of tonnage and promising them plenty of assistance in performing their duties. This letter runs as follows:

"You have no doubt read the proclamation of the President to all engaged in coal mining. Nevertheless, even though you have read it before, please read it again carefully.

"The President is our commander in chief; therefore, upon him is the responsibility, and we must assume that he is thoroughly familiar with all conditions, particularly those surrounding the supply of coal and its importance not only in assisting to win the war, but in aiding us to win it as speedily as possible, thereby lessening the loss of life.

"In this emergency there are probably no officials on our staff who are more important than the mine foremen, for they are directly in charge of the mines. Upon the mine foreman depends almost entirely the success of the company in securing the coöperation of all of the employees. He must possess courage; he must possess brains and the will to use them, and, of course, a familiarity with the best methods of mining. I want to speak frankly to the mine foreman and to say that I can readily see that at times in a large organization he may not feel that his work is properly appreciated, either by a recognition of the value of his ideas, or by a proper compensation for the work that he is called upon to perform. For that reason he may not work at times with quite the spirit and will that he would exhibit if entirely contented. I recognize that in some cases miners are making more money than the mine foreman over them. We have always considered that the mine foreman who was efficient and attended to his duties had a permanent position and was not subject to such fluctuations in earnings as is the miner. I am giving special attention to the subject of proper compensation for our mine foremen. In the meantime, I ask each of them to remember in what an important way his job promotes the interests of the Nation, and I trust that as far as compensation is concerned the matter will be worked out satisfactorily.

"With the scarcity of labor from which we are now suffering, and which will be accentuated by the draft, the necessity for handling labor to the best advantage is, in our experience, greater than ever and, in my judgment, the mine foreman should keep the following points in mind: 1. To get and keep in personal touch with every one of the men under him. 2. To see that all working places are kept in proper condition. 3. To give special attention to the subject of ventilation, as men cannot work with full efficiency in poor air. 4. To see that all supplies needed by the miner are promptly furnished and placed where they are easily accessible to him. 5. To see that all mining machinery is kept in the most efficient condition and used to the best advantage. 6. To see that all locomotives and cars are kept in the best possible condition, repairs promptly made and cars properly lubricated. 7. To see that all mine tracks, and their electric bonds, are kept in perfect condition.

Mine Foremen Should Welcome Assistance of Others

"In order to give himself full opportunity to use his brain to the best advantage, the mine foreman should ask for such assistance as is necessary for the satisfactory operation of the mine. We have recently placed section foremen under the mine foreman's charge, it being our intention that one section foreman shall not have charge of more than 25 men, each section foreman, of course, reporting to the mine foreman. These foremen should be of great assistance to the mine foreman in making out his reports, from which he can study his plans for efficiency and operation.

"At many of our mines men are laying off for various reasons, some of which are inexcusable. The mine foreman should study with the mine committees, now being appointed, the best way of correcting the habit of delinquency and how to secure the coöperation of the men in the effort to mine more and cleaner coal. When punishment is administered for delinquencies of any character, it should be done with great care and judgment and only after the mine foreman is satisfied that such punishment is well deserved.

"I think the miners as a whole now fully appreciate how important is clean coal for the efficient service of the Nation. The mine committees, I believe, will readily recognize how important it is. All the officers of the miners' organizations have said that a man who at this time loads dirty coal is a traitor to the Nation. However, where it is impossible for men to load clean coal and get out a quantity sufficient for them to earn fair wages, an investigation should be made, and the question taken up with the division superintendent as to whether the men so situated should not have an allowance made while those conditions prevail.

EDITORIALS

A Kentuckian Advocates Bonuses

A STRIKING feature in the Labor Department of this issue is a letter from a general manager who is in charge of big mines in Kentucky. The communication presents arguments in favor of the much-abused bonus, though we do not believe the writer need have any misgivings about the propriety of making public his defense of a proper bonus system. We do think, however, that he is a little unfair to the union, for since the war commenced the United Mine Workers of America, as a body, has been a frank supporter of increased production.

Opposition to bonuses arises from two sources. The operators oppose such bonuses as are planned for the purpose of inducing men to change their places of work. Bonuses introduce competition for labor and increase the labor turnover. Also, they reduce the margin of profit to too low a figure. Mr. Garfield rests his objection on the same basis. In his fulmination against these provisions on Aug. 5 he said: "Information is reaching me that coal operators are bidding against each other for labor by means of bonuses. This evidently causes unrest, and it shifts, but does not increase the total production of coal."

The union objects to bonuses because it claims the bonus is recognized only as a temporary concession, and one to be revoked at pleasure. It is regarded as a free gift of the operator, and the union does not approve of such gifts. The union's slogan, if we may make a guess at it, runs thus: "No good gifts are obtainable without the good offices of the union." The operator who pays a bonus is like the stranger who gives the youngster a dime and thereby convinces him that his father is parsimonious should he refuse to do the same. The union does not approve of free-will offerings of any kind. When these are being distributed the union is liable to be confronted at any time with the criticism, "There is a dollar that you overlooked."

Discontent between those earning bonuses and those not earning them, and not located at mines where they can earn them, adds to the embarrassment. We really believe that if the union could, by actual contract, force the operator to pay a bonus for all tonnage mined above a certain amount, and so could obtain credit for the change and at the same time could make the modification general, it would be disposed to stand sponsor for it. It could not then be charged with laxity, and there could be no heartburnings between the members of the union because some received it and some did not; being general, the bonus would not increase labor turnover.

As is pointed out in the letter referred to, the bonus is, in many cases, really earned. The operator who gets the larger tonnage is helped to lower his operating costs. When a man works until quitting time the flow of coal is rendered more equal through the full eight hours, and conditions are favorable for a maximum use of the mine force. Nothing is more wasteful than the drag in operation after the noon hour. Men scurry everywhere trying to find enough coal for a trip. As soon as work begins to lag and the roadway is full of the lights of departing men, the trips are but half as large as in the morning rush hours. Usually the mine is shut down before the full day has run its course, but when men are scarce the day force is kept on so as not to discourage the men; and when coal is at a premium the day men are sent around hunting cars because the steady miner must be rewarded and every ton available secured.

We have said that the bonus is, "in many cases," really earned. In some mines, however (at least after the war is over), the operator will find himself less able to profit by a large tonnage from each man, for he will have men enough to keep the flow of coal going at full force without any such large unit production. A bonus, then, may make it essential for his financial stability to keep unit production below the level at which the bonus begins and make him as anxious to restrict tonnage as he is now to encourage it.

That is looking far ahead, and some will contend that so long as the bonus is kept around 10c. per ton and is arranged to start at a reasonable figure really representing average production it will almost always be amply earned whenever and wherever it is awarded. How many general managers in Kentucky and elsewhere have longed for a full eight-hour day, with full trips and a sure flow of coal? And in the stub end of the working day how much coal might we not haul with the force of labor on hand if only the miners observed the appointed hours as well as their fellow mine workers?

When the Goddess of Liberty Speaks

IN THIS ISSUE appears a colored insert to call the attention of our readers to the coming sale of Liberty Bonds. The war has put our artists as well as our mechanics to the test. Uncle Sam is no longer the beaming, genial, if somewhat bizarre, gentleman he formerly was: Columbia has surrendered some of her grace while gaining force of character, and here is the Goddess of Liberty full of cares and trouble, though strong in purpose and in courage.

The countenance of the nation is changed, as have been also the faces of its great symbolic figures. The great mission with which we, with our Allies, are charged—no less a task than to give the world a new birth in freedom—has added a new seriousness to our outlook, and has given us an idealism to which, at one time, we believed ourselves to be strangers.

After all there is something larger than money in this world. There are purposes which far transcend personal advantage and private gratification. The war has

shown us that our money and our labors have value only as they promote worthy ends. They are the instruments of service and not merely the playthings of pleasure.

We are asked to invest our money in liberty, freedom of trade, freedom of travel, democracy and honor. And we will invest it freely, for, if we win this war, the world makes a step forward on the road of human brotherhood. Law is henceforth to be founded on the consent of the governed, and is the strong man which, entering the household of this world, will despoil war of its ill-gotten goods.

The appeal to invest is not made on the basis of the interest paid or on the ground of the security offered, though both are ample. National loans are not being floated on these narrow grounds. People said when the war first started, back in 1914, that a loan of a billion dollars would bankrupt the strongest of nations. They reckoned ill who cast up their column without adding in the forces of patriotism. Those ideals never proved stronger than they have done of late in the sale of Liberty Bonds. Each issue has been a revelation of the national solidarity. It has convinced us that there is between man and man a cement of mutual interest and esteem that will stand almost any strain.

We shall put aside the pleasures our wealth can buy that we may see the wonders our wealth can perform and the good our wealth can effect. We will deny our bodies that we may feed our spirits with a new vision of noble achievement. We will be narrow in detail that we may achieve a stupendous result. Every little economy, every little denial will be devoted to filling the golden stream of effort that is setting full from our Atlantic coasts toward the battle line—victory line—in France.

This Is the Day of the Spoken Word

A TIME of increased democratization is at hand. Unless the mine official is prepared to do his duty as a molder of public opinion the floodgates of order and fair play are apt to be swept away. More and more we shall find that it will be necessary for the managers of our mines and factories to be leaders of men, able from the platform to place the right cause in the right way before their men.

Someone complained to Sankey that his songs were set to the Devil's music, and he responded that he did not propose to leave all the best tunes to the Devil. Similarly oratory has been used by men of Bolshevik tendencies, but it is a weapon that can be drawn in a good cause as well as in a bad. When labor feels its power and uses it the only weapons of defense will be the oratory of those whose outlook is broader, painful experience and general reading. Perhaps the most potent of all these forces and the least harmful in operation will be the oratory of the natural leaders of men. Happy will be the time when we can argue our difficulties to a conclusion rather than force a result by strikes, lockouts, discharges and wars.

In the matter of oratory the welfare and safety men are showing the way. They will not absorb the whole stage, however. After a while the operating officials will realize that the platform calls as insistently on them as on any one else.

Electrification Not a War Necessity

MANY ARE THE problems in electrification from coal-mining centers which we will have to work out carefully in times of peace. There is no doubt that, when that time comes, they will be solved quite successfully. The extremists are already quite sure of their ground, but until more work has been done and until the end of the war makes experiments safe the public will prefer to do nothing revolutionary. The electrification of railroads is one of these problems.

The Norfolk & Western Ry. electrification has reduced the cost of freight movement per ton 26 per cent. and increased the volume of traffic 50 per cent.—a noteworthy result. This does not agree with the views of the ardent propagandist. He would suggest that a gain of two-thirds is possible. What gain has been made has arisen largely from the fact that the capacity of the railroad in question had reached its limit under steam operation. By replacing steam by electricity as the motive power a larger tonnage has been attained with consequent saving. It is thought that, had the railroad been electrified in 1905, the change might not have paid; that had it been electrified in 1910 there would have been no marked saving. It is because the business done since 1915 has been large that electrification has so clearly justified itself.

Before the tonnage handled was held down to a certain maximum by the difficulties in operating the Elkhorn tunnel, and it will probably in the future be strictly limited by the restrictive capacity of that critical point.

In order to make the electrification economically feasible it has been necessary to take special precautions to prevent too high a load factor. Portable telephones have been installed permitting the conductor or the engineer of the leading locomotive to notify the power director that the train is made up and ready to start. However, the train dispatchers are not advised by the power director unless the train is to be held more than about ten minutes.

By such careful adaptation of means to ends the installation has been so successful that the Norfolk & Western is extending it twelve miles from Vivian past Welch to Farm, and also five miles from Welch to Wilcoe. The electrified road will then be 41 miles long. But with all its experience the railway is not electrifying the stretches between Williamson and Farm—70 miles—and between Bluefield and Roanoke—106 miles. The complete work will come in time doubtless, and it will then be justified in the results attained; but for the present the installation of another 17 miles of electrification is satisfying the management or is being imposed upon it. The railroad may well desire to spread reconstruction over a term of years, but our legislators as ever will rush boldly in where railroad men still fear to tread.

In the five-year period ending Dec. 31, 1917, there was a total casualty list on American railroads of 980,565. Of this number 48,801 were deaths and 931,764 were injuries. During this period, 1391 passengers and persons carried under contract were killed and 55,887 injured; 14,652 employees were killed and 815,897 injured; 32,879 other persons were killed and 60,080 injured.

Who Says the Miner Can't Ring the Bell?

UNCLE SAM:-"THE STEEL MEN, THE SHIP BUILDERS, THE ARMY, THE NAVY, THE AVIATORS ARE GOOD HARD HITTERS, BUT THE MINER HAS THE BUSTER WALLOP OF THEM ALL. SO PLANT THE MALLET SQUARE ON THE BLOCK AND UP SHE GOES"!

COAL AGE

DISCUSSION BY READERS

Man Power and Longwall Mining

Letter No. 1—It was with pleasure that I read the excellent article of F. A. Pocock, *Coal Age*, Aug. 22, p. 350, bearing on the peculiar advantage of longwall mining as a means of utilizing the present limited man power to the best advantage to insure the production of the largest possible output of coal.

At the outset, Mr. Pocock announces that his remarks do not apply to the anthracite region but are particularly applicable to the entire bituminous field of Pennsylvania. He asks two pertinent questions: "Is there no way of increasing the tonnage per worker? Can the thinker not make the worker more productive?" Let me answer both of these questions in the affirmative, basing my conclusion on the conviction that the adoption of the longwall method of mining where the conditions will permit is the solution to this problem.

In the present crisis, the country must have coal and it must have soldiers, which makes it necessary that the tonnage per man be increased. With Mr. Pocock, I believe that the key to this situation is the longwall method of mining. As proof of the correctness of this conclusion, let me cite an instance of its practical application, recently, in my own experience.

The Virgin Run mine of the Coke City Coal Co. is situated on the Pittsburgh & Lake Erie R.R., about 4 miles

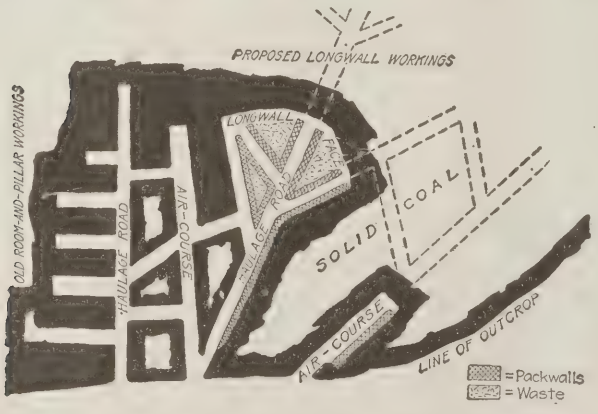


FIG. 1. ROOM-AND-PILLAR WORKINGS ABANDONED FOR LONGWALL

below Dawson, Penn. As shown in the accompanying illustration, Fig. 1, this mine was originally worked on the room-and-pillar system, there being five rooms driven off a single pair of entries. The average thickness of the coal was 44 in., which was improving slightly as the entries advanced under the hill. These entries and rooms had been driven about 10 years ago. On taking possession of the mine, recently, the new company cleaned up the falls and laid tracks to the faces of the entries and rooms, which work was completed May 20, 1918, when the company was ready to ship coal.

The mine proved a tough proposition, operated on this plan. Four or five miners were employed in the rooms and they worked hard, almost burning out the coal with the excessive charges of powder they were compelled to use in blasting. In the start of the work, I saw clearly the impossibility of the undertaking and proposed to the management to put the mine on a paying basis if permitted to open out on the longwall system of mining.

For some time the company refused to consider my proposition, but it finally gave reluctant consent to my trying what seemed to the officials to be a doubtful method. The attempt was permitted to be made in a corner of the hill, to the right of the present opening.

Starting the Longwall Work

As shown in Fig. 1, I at once started a 14-ft. entry at the mouth of the old air-course, driving it on an angle of about 30 deg. to the right of the latter. As luck would have it, the conditions here were particularly favorable to my plan. The pitch of the seam was such that the gateways turned to the left of the new entry afforded an easy grade for handling the loaded cars using a mule to haul the cars.

Desiring to make all speed possible, when the new entry was driven about 40 yd. I opened up a longwall face in the usual manner. Two men were put on night shift and kept busy taking down rock and building packwalls on the gateroads.

My longwall experience, in Derbyshire, Nottingham and Yorkshire, England, convinced me that *coal digging* was not *coal getting*. Someone had taught the miners how to *get* coal by longwall, in the mines of those counties, and I reasoned that it was possible to teach men to do the same here. My first efforts were to bring the miner to understand that the overburden of the seam is utilized to break the coal in longwall, instead of using powder, as in room-and-pillar work.

Overcoming the Prejudice of the Miners

A few minutes' talk with a good miner convinced him of the comparative ease promised by the new method. I explained how it was necessary to cut two tight ends when driving a room or entry, and the man was quick to see that in longwall work, the coal was slabbed and that, when mined, no powder was needed but the roof pressure broke down the coal ready for loading. After that the miners were not slow to see that things were coming their way, and it was difficult to keep them on the old work where a miner would average about three cars a day as compared with eight and twelve cars a day in the longwall section.

About this time, however, I experienced my first difficulty in the longwall proposition. As the men were transferred from the old to the new work, trouble arose from attempting to put the one Slav to work with an Italian miner. I was forced to tell the Slav that he must bring a buddy the next day or work with Tony for whom he had no liking. The big wages the Slav was

making however, made it easy for him to secure a buddy whom he liked.

The rapid progress of the work, under the new plan, soon showed that the equipment of mules and cars was not sufficient. It was impossible to satisfy the men, as I could not give them the cars they could load. The longwall face had been extended so that there was now room to work eight men, and more animals were needed to haul the coal. Trouble again arose when Tony had to work with three Slavs on the same face. The result was that the first day Tony had one of the Slavs by the neck, disputing his right to one empty car, while on that face 20 carloads of coal were down and ready to load.

Taking out all the coal as the face advanced suggested to some the possibility of a general cave, but most of the men had full confidence in the new plan.

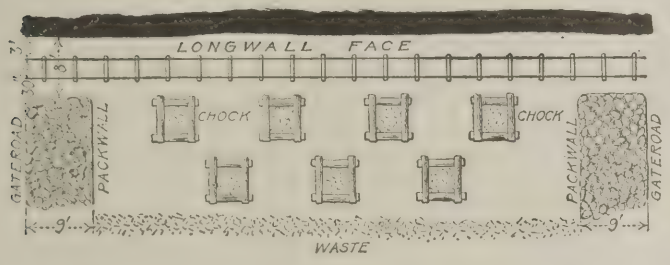

FIG. 2. TIMBERING A LONGWALL FACE WITH CHOCKS

As quickly as the face advanced, as shown in Fig. 2, chocks were built for the support of the roof over the face track, which was moved forward from time to time. On the gateroads 2½ ft. of rock was taken down for building the packwalls shown in the figure. This gave good headroom on the road and it was no longer necessary to take rock to the surface. The packwalls were 8 or 9 ft. in thickness and well built.

Owing to the longer working face, it is clear that there were less roads to keep up, while the extra expense of building the packs never approached the expenditure for timbering and trackwork, in the old system. It will generally be found a good plan to build a chock filled with rock every 40 or 50 ft. in the roadpacks. This will provide for a more permanent roadway when the roof has finally settled on the pack.

In closing, let me say that the success of this operation shows that it is possible to make good longwall miners of men who have been trained for room-and-pillar work. It will pay operators who are skeptical, in regard to the adaptation of the longwall method of mining to their conditions, to investigate this system and, if necessary, make a trip to those sections of England where the method is largely used.

Connellsville, Penn. JOSEPH A. GREAVES.

Ventilating a Gassy Slope Mine

Letter No. 4—Referring to the request of "Mine Foreman," *Coal Age*, July 25, p. 191, asking for information in regard to the best method of ventilating a slope mine, when the seam has a dip of 6 per cent. and generates much gas, let me say, sufficient data are not given to enable one to handle this subject except in a general way. To be able to discuss this matter intelligently it would be necessary to know the size and shape of the field and extent of the mine to be ventilated. also the source of the gas, whether in the roof or the coal; also the capacity of the mine or the expected daily tonnage.

However, assuming that the field is large and of a shape that would permit, I would drive not less than four main slopes abreast, or five if the field was large enough to make that number necessary to comply with the law. These must be driven on the full dip of the seam. If only three slopes are driven, as suggested, and two of these are used as returns there will be no travelingway, unless the men traveled to and from their work on the haulage road or the return air-course, neither of which would be advisable.

MAKING AMPLE PROVISION FOR VENTILATION

A single main intake would not give enough air to ventilate such a mine, especially when you consider that the inlet would be blocked by trips a part of the time. Furthermore, if the mine became very extensive it would be impossible to circulate the required amount of air, under 1 to 2 in. of water gage, and using a single intake.

The fan should be large enough to furnish the required circulation of air, under a water gage not greater than 2 in. and, to accomplish this, it will be necessary to make the conditions in the mine conform to that requirement. It must be remembered that it is practically impossible to make a given fan give the same air with a less gage, or more air with the same gage, as the resistance of the mine determines the water gage for a given volume of air.

In planning a mine of a certain tonnage capacity, the necessary circulation must be estimated to comply with the law regarding the number of men employed and the gaseous condition of the seam. The volume of air so determined should be circulated under a water gage of, say 2 in., which fixes the size and power of fan required The circulation in the mine must then be arranged, by splitting the current, so as to pass the required air under this gage.

INSTALL DUPLICATE EXHAUST FANS

This mine should be ventilated on the exhaust system and all haulage roads and travelingways arranged on the intake air-courses. The fan should be so constructed that it can be operated by either one of duplicate engines, in case of needed repairs or in an emergency The fans should be of sufficient size to yield a fifty per cent. increase, if necessary.

If four main slopes are driven, the two center entries should be used as intakes, haulage roads and travelingways, and the two side entries as return air-courses. Levels or flat headings should be turned to the right and left of the main slopes, and driven three abreast, the two upper levels to be intakes and the lower one the return. Butt- or room-headings should be turned off the flat entries and rooms opened off these butts.

The air should be split at the bottom of each pair of butt-headings and, after ventilating these entries and rooms, it should be carried down the parallel entry and across two overcasts into the return. This system will require a split for each pair of room-headings and no doors will be necessary. If the mine is not making too

much gas it may be possible to ventilate two or more sets of room-headings with one split of air and, in that case, air-lock doors should be used at the mouth of each pair of entries, except the one where the air was first split, after which it could be carried by the overcasts into the return.

The question may be asked, why not make the two lower entries intakes and the upper entry the return, if each pair of entries is made a split, as that would save building the extra overcast at the bottom of each pair of room-headings. This is done so that when they start to draw ribs and stumps in the cross headings they can cut through into the return air-course, on the flat above, and drain the gas from the gobs directly into the return, forming what is known as drains or "bleeders."

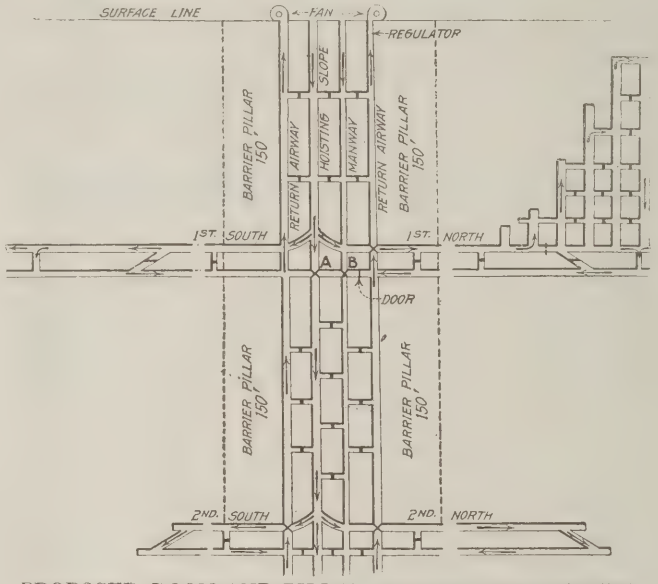
Advantage of Driving Levels Four Abreast

If the cost of driving entries is not too great, four flat headings can be driven, the two center ones to be used as intakes and the two outside entries as returns. This would only require one overcast for each pair of cross-headings. Using the two center slopes as intakes permits the laying of tracks in the extra entry, for use as sidetracks or "run-arounds" and make a good haulage system and needs no doors. Where the air is split on the main slope overcasts will be required to carry the return from the lower sections of the mine across the roads going into the flats.

This mine should be worked with approved safety lamps or electric cap lamps, in conjunction with safety lamps. Permissible powder should be used and competent shotfirers employed to charge and fire all holes.

Some attention should be given to the grades at which the headings are driven. The main slopes can be driven on the full dip of the seam. The levels or flat headings should be driven with about a 2 per cent. grade in favor of the loads. The room-headings are driven on an upgrade of about 3 per cent. in favor of the loads. Rooms turned off the room-headings are driven about on the same grade as the flats.

Richard Maize, Mine Inspector,
Uniontown, Penn. Fifth Bituminous District.



Letter No. 5—I have followed the discussion in regard to the best method of ventilating a slope mine generating large quantities of explosive gas, with much interest, and desire to submit the following, which appeals to me as being best adapted to the conditions outlined in the inquiry that appeared in *Coal Age*, July 25, p. 191:

As the efficiency of any ventilating system depends, to a great extent, upon the method adopted in the development of the mine, I have prepared the plan shown in the accompanying figure. My opinion is that a slope mine, opened in a seam generating large quantities of gas, should not have less than four parallel slopes sunk on the full dip of the seam.

As indicated in the figure, the exhaust system of ventilation should be adopted. In this arrangement, the main hoisting slope and the manway, being the two central slopes, are intake airways, while the two side slopes are the return airways for their respective sides of the mine. Since the men are warm when coming out of the mine, the air in passing down that slope must be controlled by a regulator so as to reduce the draft to which they are exposed.

The hoisting slope is 7½ x 14 ft. in the clear and the manway 7 x 7 ft. in the clear, while the two air-courses should each have a sectional area not less than 64 sq.ft. If desired, steps can be provided in the manway by running poles 6 in. in diameter across the slope and hitching them into the rib or supporting them behind the legs of the timber sets. On this inclination, however, that may not be thought to be necessary.

Two fans are shown in the figure, one located at the mouth of each return airway. These should be reversible so that the air current can be reversed, if that is

PROPOSED ROOM-AND-PILLAR RETREATING SYSTEM

necessary. I would install one fan only the first year, and let the other wait until the development of the workings required an independent circulation for each side of the mine. I consider this a very necessary precaution to take in a mine subject to large inflows of explosive gas.

Each fan should have a capacity sufficient for the ventilation of the entire mine. In order to accomplish this, however, overcasts must be built at *A* and *B*, while the door shown in the crosscut divides the circulation and when closed makes each fan independent of the other. As a further precautionary measure, these fans should be provided with two independent sources of power, steam and electricity, so as to guarantee their continuous operation.

Further explanation of the plan shown in the figure is unnecessary, except to say that if the requirements of the company will permit, I would adopt the room-and-pillar retreating system, driving the levels to the boundary before turning any rooms. This plan will greatly simplify the ventilation by allowing large quantities of gas to be drained off before attempting any extraction of coal in the rooms.

It should be observed that the crosscuts are shown on this plan as far apart as possible, which will give stronger pillars on both the slopes and the entries, besides decreasing the number of stopings required, which are always a source of leakage of air. By employing a booster fan and using flexoid tubing 16 in. in diameter where the room will permit, the distance in crosscut yardage will soon pay for this equipment.

Cassidy, B. C., Canada. J. W. Powell.

Loading Coal at the Face

Letter No. 4—I read with much interest the letter of Thomas Hogarth, *Coal Age*, Aug. 8, p. 282, referring to the record made in the loading of coal by Ed. Blagg at No. 1 mine of the Buckeye Coal and Railway Co., San Toy, Ohio. As stated by Mr. Hogarth, Mr. Blagg is reported to have loaded 508 tons of coal in 22 working days of 8 hr. each, in the month of May.

Like many others, I was tempted to doubt the report. Having worked at the same mine, in the year 1906, I know what a person has to contend with in that mine, in loading such a tonnage as that stated. The seam of coal averages about 3 ft. 8 in. in thickness and is overlaid with from 6 to 8 in. of bone coal.

In entry work the bone coal is taken down with every cut taken out, and it requires one large car to remove that bone from the entry. Judging from my own experience, Brother Blagg would have to load two cars of bone to every 20 cars of coal, making a total of 22 cars loaded each day he worked at the face. As just stated, I had a suspicion that something was wrong and wrote Brother Blagg for first-hand information, and Sam Walters, to whom Brother Blagg referred my letter, sent me the following official statement, which he vouches is correct:

AUTHORIZED STATEMENT OF TIME WORKED AND TONNAGE OF COAL LOADED BY EDWARD BLAGG, DURING THE MONTH OF MAY, 1918

Date	Hours Worked	Tonnage	Date	Hours Worked	Tonnage
1	8	20	16	7	17
2	8	18	17	8	23
3	8	22	18	6	14
4	8	25	20	8	20
6	8	27	21	8	27
7	8	21	22	8	16
8	8	23	23	8	21
9	5	10	24	8	26
10	8	31	25	4	3
11	4	7	27	8	22
13	8	23	28	8	24
14	8	12	29	8	19
15	8	19	31	8	18

This coal was loaded on bank time only. The 7 tons loaded May 11, and the 3 tons, May 25, was all the coal down those days.

The statement shows the number of hours worked each day and the tons of coal mined. It shows that, instead of this output (508 tons) being the work of 22 days, as reported, the exact time worked was 24 days and 2 hours, mine time.

Notwithstanding the error of 2 days, and 2 hours made in the first report, we must admit, as mining men, that Brother Blagg accomplished a great feat, considering the disadvantages existing in that seam in getting the coal ready to load. To my knowledge no person in this part of the country has ever before made such a record, and I want to say that if we had an army of coal loaders such as Ed. Blagg, we would not suffer for a lack of fuel next winter. JAMES H. TAYLOR.

Poston, Ohio.

Travel of Electric Current

Letter No. 5—In reading the discussion of this subject, in *Coal Age*, I could not fail to observe the different aspects in which the several writers viewed the situation presented in the flow of electricity in a conductor. In this, as in most other controversies, it is probable that both sides are partially correct in their contention. What we are pleased to call the "electric current" may be the actual flow of something in a conductor, while, at the same time there is something going on outside of or surrounding the body of the conductor and which is incidental to the current.

The flow in the conductor, when the current is direct or continuous, is probably uniformly distributed throughout its entire cross-section. In other words, when such a current is flowing extremely minute particles of negative electricity called "electrons" move along longitudinal lines through every section of the conductor. On this assumption, an electric current has been defined as "a flow or movement of electrons."

Now, consider what happens at the same time outside the conductor. When the so-called current is flowing through a conductor, a magnetic field is established about the latter. Seemingly, then, the whole discussion hinges on our definition of an *electric current*. Do we understand this term to refer primarily to the flow that takes place within the conductor, or to the external magnetic field incident to and associated with the former?

Reference to electrical authorities reveals no general agreement as to the meaning of the term. Until this morning, I have never had occasion to compare the different definitions given by many books on the subject. I find that no two of them appear to be the same, which, to say the least, is confusing to one in search of exact information.

Personally, I prefer to define an electric current as the flow of electricity through or within the conductor, meaning by that the movement of electrons within the body of the same. I like to regard the effect outside of the conductor as a distinct phenomenon and incident to the current in the wire.

The Electron Theory Helpful

Probably, the actual situation can be most readily understood by adopting the electron theory. In my book, "Practical Electricity," I have endeavored to set forth this viewpoint in an elementary way. My belief is that when one adopts the electron theory and becomes familiar with its essential elements, which practical men may grasp with little effort, many things concerning electricity that were previously regarded in a vague and hazy manner become clear.

Allow me to urge that every electrical man, the practical man in particular, familiarize himself with the fundamental conception of the electron theory. From experience, I know that this will be of great value to his understanding of the subject.

Following are some of the definitions that I found in my search for the true meaning of the word "electric current":

CURRENT, ELECTRIC—A continuous flow of electricity along a conductor; also the rate of flow of the electric fluid through a conductor, representing the ratio between the electromotive force and the resistance.

CURRENT, ELECTRIC — A continuous flow of electricity a conductor, from the higher to the lower of two points having different potentials.

An electric current is defined as the rate of flow of electricity, or the quantity of electricity which flows through a cross-section of the circuit, per unit of time.

The quantity of electricity, per second, which passes through any conductor or circuit when the flow is uniform

It is my hope that the American Institute of Electrical Engineers, or some other qualified authority, will soon define for us the meaning of this term in a manner that will give to it a definite significance.

St. Louis, Mo. TERRELL CROFT.

INQUIRIES OF GENERAL INTEREST

Blackdamp on Pitches

Working at the face of a 35-deg. pitch, in a mine operated in the Buck-Mountain seam, I have experienced some difficulty in the ventilation of my place. What I have taken to be blackdamp appears to hang at the face of this pitch. The gas dims the light and, in other respects, suggests that it is blackdamp.

As is well known, however, the ordinary blackdamp is much heavier than air and accumulates at the face of dip workings and other low places in a mine. It is not natural to find it at the face of a pitch, and I want to ask, Is it possible for blackdamp to hang at the face of a chute pitching 35 deg.? MINER.

Shamokin, Penn.

Before answering these questions, it will be well to understand what is meant by the term "blackdamp," which miners generally think is carbon dioxide (CO_2).

Originally, the term "damp" was used to describe mine gas, as distinguished from pure air. The meaning of the term was a vapor or fume. Later, as miners came to distinguish between gases having different properties, they applied the terms "firedamp," "blackdamp" or "chokedamp," "whitedamp," "afterdamp," "stinkdamp," etc., according to the particular characteristic or nature of the gas observed.

Thus, the true significance of the term "blackdamp" is a gas or mixture of gases that dims or extinguishes the miner's light, leaving him in the dark. The term does not apply to carbon dioxide any more than to nitrogen, but describes an atmosphere deficient in oxygen, which is required for the support of life and combustion.

In a chart issued a short time ago by the Federal Bureau of Mines, the average composition of blackdamp is given as 11 per cent. carbon dioxide and 89 per cent. nitrogen. In the opinion of *Coal Age*, however, it is not possible to give an invariable or absolute composition of blackdamp. It is, on the contrary, a *variable* mixture of extinctive gases, in this respect resembling afterdamp. The term cannot be applied to carbon dioxide unmixed with air or other gases. That is to say, blackdamp and carbon dioxide are not synonymous terms. Likewise, the term "firedamp" cannot be applied to methane or marsh gas unmixed with air. It is a question, also, whether the term "whitedamp" is synonymous with carbon monoxide, as that gas does not represent the mixture the term described in its original meaning.

Returning now to the question asked by our correspondent: What he has very properly called "blackdamp," owing to the extinctive quality of the observed gaseous mixture encountered at the face of the pitch, is not carbon dioxide as he may wrongly assume. It is a true blackdamp mixture, having a specific gravity but slightly greater than that of air. Because of its temperature being somewhat higher than that of the air on the gangway, such a mixture will tend to hang at the face of the pitch.

Taking for example, the average composition of blackdamp as given by the Bureau of Mines, in the chart just mentioned, namely, 11 per cent. carbon dioxide and 89 per cent. nitrogen, since the specific gravity of these gases is, carbon dioxide 1.529 and nitrogen 0.9713, the specific gravity of the assumed mixture would be

Carbon dioxide,	$11 \times 1.529 =$	16.819
Nitrogen,	$89 \times 0.9713 =$	86.446
	100	103.265

The specific gravity of this mixture is, therefore, $103.265 \div 100 = 1.032$, showing that the assumed mixture is slightly heavier than the same volume of air, at the same temperature.

It should be mentioned, here, that such an atmosphere as the one just described cannot be assumed to exist in a mine. It is probable that the air at the head of the pitch referred to by the correspondent approaches a *residual* atmosphere, in which a portion of the oxygen has been consumed by the breathing of the men and the burning of the lamps, and there has been produced, besides, a certain amount of carbon dioxide.

Under these conditions, a residual atmosphere becomes extinctive of a lamp flame when it contains about 3 per cent. of carbon dioxide. The composition of the air, at that stage, is as follows: Oxygen, 16.6 per cent.; nitrogen, 80.4 per cent.; carbon dioxide, 3 per cent. The specific gravity of these gases being: Oxygen, 1.1056; nitrogen, 0.9713; carbon dioxide, 1.529; the specific gravity of the mixture forming a residual atmosphere is calculated as follows:

Oxygen,	$16.6 \times 1.1056 =$	18.353
Nitrogen,	$80.4 \times 0.9713 =$	78.092
Carbon dioxide,	$3.00 \times 1.529 =$	4.587
	100.0	101.032

The specific gravity of this mixture is, therefore, $101.032 \div 100 = 1.01$, which shows that such an atmosphere is slightly heavier than the same volume of air, at the same temperature. To make the density of this mixture equal to that of air, assuming the temperature of the air on the gangway is 60 deg. F., would require a rise of only 5 deg., which probably represents more or less closely the actual condition in this case. Assuming a somewhat slack ventilation of the place, this difference in temperature would easily be attained, owing to the burning of the lamps and breathing of the men working in the place, together with the heat radiated from their bodies.

It is possible, also, that there is an inflow of carbon dioxide into the chamber, either from the coal or from adjoining workings further up the pitch, or from an overlying seam, in which case, the conditions at the head of the pitch would be aggravated. We shall be glad to have this question further discussed by readers.

EXAMINATION QUESTIONS

Kansas Firebosses' Examination Pittsburg, May 15, 1918

(*Selected Questions*)

Ques.—What are the lawful duties of a fireboss?

Ans.—The rules governing the operation of coal mines in the State of Kansas, as they relate to the duties of the fireboss, require him, before going into the mine to first clean and examine his safety lamp and then examine the fan and fanhouse to see that no unusual conditions exist. He must never take an open light into the mine, but must be provided with an electric light when the light given by his safety lamp is insufficient.

He must observe and see that the air is traveling uniformly in its usual course; examine all doors and curtains to make sure that they are in good condition and not leaking, which would allow gas to accumulate in the workings. Where gas in dangerous quantity is found, the fireboss must place a danger signal and permit no one to enter or work in such places, until they are cleared of gas and safe for work. He must permit no one to work on the return air where he has discovered a gas feeder.

Ques.—If, upon making an examination of a mine, you discovered explosive gas in the intake air current of one of the splits in which 45 persons are employed, how would you proceed to protect the workmen?

Ans.—Notify the men at once to extinguish their lamps, proceeding in order from place to place and instructing everyone to withdraw as quickly and as quietly as possible from the mine. This is assuming that the test mentioned showed a dangerous percentage of gas present in the air current.

The percentage of gas that can be considered dangerous will depend very largely on the conditions existing in the mine, in respect to the inflammability of the coal and the amount of dust suspended in the air. If the condition is such as not to be considered dangerous for work, the men should be instructed to use extra precaution in their places; and, at the same time, every effort should be made to increase the circulation of air in that split, so as to reduce the explosive condition of the current. A careful watch must then be kept and frequent tests made to ascertain what changes are taking place and to enable due warning to be given the men in case of danger.

Ques.—After making your examination of the mine, what evidence would there be to show that you had examined all the working places? When and where would you make your reports and what information would the reports give?

Ans.—The fireboss is required to mark the date on the face of every working place examined and found to be safe for work. Where gas is discovered in a place, he is required to fence off all the entrances to the place, placing at each entrance a suitable danger signal, which is warning to all men to keep out. The fireboss' report, when properly made out, is also evidence of what places he has examined.

Immediately on completing the examination of the section of mine in his charge, a fireboss must proceed to the shaft or slope bottom or the mouth of the mine and make out and sign a written report, in a book kept for that purpose. This may be done in the fireboss' shanty near the entrance of the mine or in the office outside. The report must show the time of beginning and completing the examination, and the places examined, giving in detail any dangers that may have been found, stating their nature and where they exist.

Ques.—How would you proceed, with safety, to enter a mine, after an explosion that has destroyed the doors, brattices and overcasts?

Ans.—An examination must first be made to ascertain the condition of the ventilating apparatus and to observe the upcast current discharged from the mine. Everything will depend on the results of that examination, as no attempt must be made to enter the mine except on the intake air. Having organized a rescue party composed of experienced miners, under a competent leader, and equipped with safety lamps and breathing apparatus, which should always be available at every mine, and having gotten together the necessary supplies of tools and material required to rebuild brattices and restore the circulation in the passageways, entrance must be made by following the intake air. No advance must be made ahead of the air, which must be carried forward by constructing temporary brattices. It is necessary to proceed with caution, making frequent tests of the air with the safety lamp and by observing the caged birds or mice that must always be carried by rescuers to insure their safety.

Ques.—How would you proceed to extinguish a mine fire at different stages of the fire?

Ans.—A gob fire, caused by spontaneous combustion occurring in the waste, can generally be loaded out of the mine if taken in time. When a feeder has been ignited and is burning back under the gob the flame can sometimes be extinguished by exploding a small stick of dynamite near the place. It is not well to treat a gob fire with water ordinarily, as the moisture tends to increase the heating of the gob and extend the trouble.

A fire that has gained considerable headway by the ignition of a door, brattice, timber frame or a gas feeder in the coal must be extinguished with water or by the use of fire extinguishing apparatus. When this cannot be done, the place must be sealed off so as to prevent air reaching the fire, which should then die out for lack of oxygen to support the combustion.

When every other means has failed recourse must be had to drowning out the fire, by flooding the place where it is located. For this purpose, it is sometimes possible to build a substantial dam in the opening leading to that section and thus avoid flooding the entire mine.

COAL AND COKE NEWS

What Happened in August

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Aug. 1—Canadian railroads file new rates approximately 20 per cent. higher than those in force—Mines of the Lehigh Valley Coal Co. at Beaver Meadow are flooded by the rising of Sulphur Creek and the bursting of the Beaver Meadow silt dam [289]—Lehigh Valley Coal Co. redistricts its operations [289]—An Austrian, Alexander Frank, by name, is accused of attempting to blow up Wilson Creek mine near Carbondale, Penn. [366]—Increase in wage granted in Alberta coal mines to balance increase in cost of living [407, 457].

Aug. 2—Order establishing production committees at all local mines—Fuel Administration provides price for "sized screenings" to take the place of anthracite and to be used in magazine or base-burner stoves—Order No. 670 issued by Fuel Administration restricting the movement of anthracite coal from any of the coal docks in the States of Minnesota, Wisconsin and Illinois, and in the upper peninsula of Michigan—Conference of mine operators at Washington, D. C., relative to increased production.

Aug. 3—Price is set for the "modified mine-run" product of mines in Barton and Vernon Counties, Missouri, and in Cherokee and Crawford Counties, Kansas—Announcement is made that retail coal dealers in Minnesota and South Dakota have refunded $16,000 to their local customers, or where these could not be located to the Red Cross—During the week just ended anthracite production rose to a record figure, 1,750,490 tons.

Aug. 5—United States Fuel Administrator condemns the coal operators for "bidding against each other by payment of bonuses," threatens where bonuses are paid to assume that the coal price allowed is too high and declares that he will order a lower price in such cases—Weekly reports are required to be made to the Fuel Administration relative to domestic coke production and distribution—Delegates from 52 unions in northern anthracite field meet and demand a 25 per cent. increase in wages, time and a half for overtime and double time for Sundays without increase in selling price of coal [322].

Aug. 8—Fuel Administration orders that cement plants shall consume in the calendar year 1918 only 75 per cent. of the average annual fuel consumption between Jan. 1, 1915, and Dec. 31, 1917—Two plants may combine and pool the coal allowed and larger allowances may be given if market conditions render it necessary—Wood and peat may be used ad libitum if not brought in by railroad.

Aug. 9—President Wilson addresses a proclamation to all those engaged in coal mining, urging steady work and the duty of miners to claim and accept exemption under the selective service draft [319]—All bars are withdrawn restricting the importation of Mexicans for work at coal mines [378].

Aug. 12—New railroad rates become effective in Canada.

Aug. 15—James B. Neale announces that 28 production managers have been appointed [363].

Aug. 16—President Hayes, of the United Mine Workers of America, states that "the only logical solution (of labor conditions in the mining industry) is a substantial flat wage increase to be applied to all classifications of labor [365]—Fuel Administration orders that bona-fide contracts relative to charcoal made prior to order of July 8, 1918, shall stand. This order was privately promulgated Aug. 13—Dominion Coal Co. announces bonus to shippers and loaders [456].

Aug. 17—Fuel Administration makes order adjusting charges for handling and forwarding lake cargo coal and fuel for lake vessels [364]—Fuel Administration provides that the price of coal delivered into the tenders of engines may be 5c. per ton more than that charged for coal loaded in cars for shipment [364].

Aug. 21—Yorkshire (England) mine workers, threatening to strike against Judge Benson's award, receive letter from Marshal Foch—"Coal is the key to victory. The miners of Great Britain must help me."—United States Fuel Administration limits the amount of coal that may be stored by industrial plants [405].

Aug. 22—Yorkshire coal strike begins and comes to an end, the employees receiving concessions [420]—Meeting of district presidents of United Mine Workers to discuss wage increase urged by President Hayes Aug. 16 [365]—Interstate Commerce Commission decides that no additional charge shall be made for freight carried in privately owned cars except where the ordinary rate is based on the cost of transportation of like freight in a type of car that is more readily and cheaply handled. Increase does not apply to stock, coal, coke, rack, flat, box or pocket cars, the additional rate on which remains 3c. a mile.

Aug. 23—Cardinal Gibbons writes a letter to Dr. H. A. Garfield urging greater coal production and stating that the clergy can and will render great assistance by urging the duty of steady work upon their parishioners [541]—An order is promulgated by the Fuel Administration removing, except as to breweries, till Sept. 8 the restrictions on the purchase and use of slack and screenings west of the Mississippi River—[319, 363]. Fuel Administration promulgates a new classification of Alabama coals and specifies new prices for same [406]—Fuel Administration creates a new district in Ohio, No. 9, a subdivision of District No. 5. It includes the Cambridge and Hocking fields. The Fuel Administrator also reduces the prices of all Ohio coals except District No. 8, where adjustment has already been made.

Aug. 24—Fuel Administration announces the beginning of the erection of a "Carbocoal plant near the junction of the Carolina, Clinchfield & Ohio and the Norfolk & Western railways.

Aug. 25—Strike of men of Nova Scotia Steel and Coal Co. to compel four men to retain union membership on their advancement to official position [456, 457].

Aug. 29—Fuel Administration announces that the lamp manufacturers have agreed to eliminate the carbon filament lamp in favor of the tungsten lamp though battleships and industrial establishments where vibration is excessive will probably continue to use them. It is hoped that a million tons of coal will be saved by the use of the more economical lamp.

Aug. 31—Fuel Administration announces that by Sept. 15 it hopes to be able to put in operation a skip-stop provision for street cars which will save 1,500,000 tons of coal a year—War Industries Board orders West Penn Power Co. in Pittsburgh district, to give coal mines a full supply of power discriminating in favor of coal companies as against all other industries [453].

Harrisburg, Penn.

At a meeting of the executive committee of the Pittsburgh Coal Producers' Association on Sept. 4, plans were completed for a vigorous fourth Liberty Loan campaign among the miners of the Pittsburgh district. Philip Murray, president of District No. 5 of the United Mine Workers of America, attended the meeting by request, and will take a prominent part in the campaign.

A meeting of the miners and operators was also held, at which a committee to have charge of the campaign was appointed. This committee consists of three operators and three miners, and will have power to appoint sub-committees of three miners each, which will be stationed at all of the 300 mines in the district, to be known as the Liberty Loan committees, whose duties will be to take subscriptions for the loan. These committees will be entirely independent of the production committee appointed to speed up coal production at the mines.

Richard W. Gardiner, manager and distributor of coal production in the Pittsburgh district, stated on Sept. 6 that complaints have been received by him that certain industrial plants of the district are making a practice of distributing part of the coal assigned to them among their employees. Mr. Gardiner, in a statement issued, says that this is contrary to the orders of the Federal Fuel Administration and that he will unhesitatingly shut off the supply of any plant practicing such distribution of its coal, no matter how small the distribution may be.

Connellsville district, America's premier coke region, smashed all its coal production records for the week ending Sept. 7, according to a report made from Uniontown by W. L. Byers, production manager, to James B. Neale, Director of Production of the Federal Administration. Tonnage for the week was 718,221, an increase of 2424 tons over the preceding week and 1267 tons more than the previous high week of the current coal year.

This record is not only remarkable in itself, but is doubly so when it is considered that it is for the six-day period which included Labor Day. As it stands, it is regarded as a practical demonstration of patriotism on the part of all men engaged in the coal industry of that district. Since Connellsville coal is a great source of coke supply, the record-breaking output is a direct contribution to the nation's blast furnaces which are supplying the metal going into the guns and shells which America is shipping abroad.

Uniontown, Penn.

That a coal company is liable under the compensation law for death or injury received by policemen in its employ is the import of an award made by the State Compensation Board, allowing Mrs. Louis Vecchio compensation in the sum of $7000 for herself and nine children. Vecchio was employed as watchman for the Hustead Semans Coal and Coke Co., and was killed by Andy Medavich, another watchman, in a quarrel over their authority. Medavich is now serving a term in prison for second degree murder.

Monthly shipments of coal and coke down the Monongahela River to Pittsburgh continue to break all records. The aggregate shipments during the month of August passing through Lock No. 4 at Charleroi was 29,282,350 bushels, of which 28,563,000 bushels was coal and 719,350 bushels coke. The increase over the July shipments was 1,530,800 bushels. A decrease in coke shipments was brought about by an increased coal traffic to the Clairton by-product plants. Because of the necessity of keeping that plant supplied with coal it was necessary to shift several steamers from the coke to the coal trade.

West Virginia

The last few weeks have witnessed a marked change in production conditions throughout West Virginia, due solely to an improvement in the car supply. During the second week in September most of the districts in the state were receiving a 100 per cent. supply. Relief was not only afforded by the railroads and a pronounced increase in production shown, but at the same time apprehension lest the mining industry be badly crippled by further draft inroads was dispelled when the district draft board for the southern district of the state issued a statement that the board proposed a more liberal construction in its classification as to "skilled" laborers. At the same time production committees were beginning to secure results from an active and well organized production campaign. Circumstances, according to operators, seem favorable to an increased production during the month of September, if the record established during the last week of August is to be accepted as an indication of what it may be possible to establish. Even the Labor Day loss of production was to some extent offset by working at night during

the days immediately preceding and immediately following that holiday.

Production of coal in the New River field has within the last few weeks been increased an average of 30,000 tons a week over the normal production during August. This increase represents a gain of 7 per cent. in the field proper and 8 per cent. in the Winding Gulf district, the last named division now producing about 105,000 tons per week. The production committees for the New River and Winding Gulf fields have been busily engaged in organizing both the fields mentioned right down to each mine and each man, with substantial results to show for such work. Car supply in both the New River and Winding Gulf Districts since the first of the month has been practically 100 per cent., or equal to all requirements of the mines, the districts in question being supplied by both the Chesapeake & Ohio and the Virginian Railways.

There has also been a most perceptible improvement in the Kanawha region insofar as transportation facilities are concerned, although the betterment of conditions in that region was not apparent until last week, when the holiday cut into production. Under favorable conditions the mines in the Kanawha district are capable of producing in the neighborhood of 220,000 tons a week as against the 168,000 tons produced according to the latest figures available.

Coal has been produced in much larger quantities during the last few weeks in the Fairmont field than was the case during August, an increased car supply making this possible. While late placing of cars has to some extent curtailed production in the Fairmont field, even when an ample number of cars are on hand, this is being overcome to a large extent and operators in the district are extremely hopeful of being able to establish a new high-water mark during the current month, though this will be dependent almost entirely upon transportation facilities afforded.

With more cars available in the Tug River and Pocahontas districts and with a more liberal construction of the selective service regulations as applied to those actually engaged in mining, the industry in the southwestern part of the state is beginning to hit its stride once again, after a period of curtailed production due to a shortage of man power. While a shortage of cars has not affected production to as great an extent in the districts referred to as it has elsewhere, nevertheless it has even been felt in those districts, but in the last few days an improvement is even observable in the Pocahontas and Tug River districts.

Reverting to conditions in the Fairmont district, the operators in that region, while making no complaint as to the Monday supply of cars in that district, are not satisfied as to the supply which has been vouchsafed them and which is now being given them during the remainder of the week, and while the supply as already indicated is not as bad as it has been within the past month the number of cars furnished is far from adequate.

On the other hand, mines reached by the Western Maryland Ry. have fared exceedingly well during the last few weeks in point of cars supplied them. Such mines are located in Randolph and adjacent counties.

Elkins, W. Va.

A mass meeting of coal operators from Randolph, Barbour, Upshur and surrounding counties was held at the Y. M. C. A. Auditorium at Elkins, Tuesday afternoon, Sept. 12. The meeting was called by C. H. Jenkins, president of the Northern West Virginia Coal Operators' Association, while the directors of the state association were meeting last week at Huntington. The chief feature was an address by Mr. Fleming, who was recently named production manager for the Fairmont district. Mr. Barrett, of the Department of Labor, made a few remarks to operators outlining the work planned by that department.

Mr. Bradley told how the state coal association could be of value both to the country generally in war times and to operators as individuals. He dwelt particularly on the importance of physicians remaining at the mines and not heeding the call for service overseas, pointing out that miners would not remain at the mines if there were no physicians and that such action would mean a serious loss of production.

Mr. Fleming emphasized the necessity of increased production, and urged the operators to name production committees at their mines if that had not already been done. He discussed the necessity of putting it before the mine workers squarely that they were essential to to production of coal and therefore more needed at their present posts than in the trenches. He told of finding draft boards ready to grant exemption to mine workers really essential to production and pointed out that men taken heretofore might possibly be furloughed and brough back to the mines if still in this country. He emphasized the necessity of following out prescribed regulations where mine workers were willing to accept deferred classifications. Pressure must be brought on the mine worker to make such an affidavit, the foreman or superintendent must back this up with an affidavit that he is essential, and the operator must file still another affidavit.

Birmingham, Ala.

Coal production in Alabama during the week ended Aug. 31, totaled only 390,413 tons, as compared with 430,311 tons produced during the preceding week. The slump in production is attributed chiefly to the effects of payday, though there is some complaint also of car shortage. Col. H. E. Hutchens, district director of the railroad administration, states that practically 100 per cent. was attained during the week in furnishing freight cars for coal transportation to the miners. He declines to attribute any of the shrinkage in production to car shortage.

Another drawback in production for the week ended Aug. 31 was the loss of four days work at the Lewisburg mines, where a cloudburst did much damage, drowning four men and wrecking the main entry and flooding the mines. These mines had a daily output around 1250 to 1500 tons.

Among the interesting announcements in Birmingham coal circles during the week was the reported purchase by the Texas Steel Co. of Beaumont, Tex., of two coal beds in this district. The company, according to this announcement, expects to build coke ovens and manufacture coke to be used in some prospective steel works in Beaumont. One of the coal beds purchased by the Texas company is situated on the Warrior River, close to the Louisville & Nashville R.R., and is estimated to contain more than 2,000,000 tons of fuel. The other property is located in the same section and is known to contain a large tonnage of coal.

The coke production in Alabama and the Birmingham district for the past week is holding near maximum, though the Alabama company is expected to cool down its coke ovens at Lewisburg because of the coal shortage resulting from the mine accident there. It will require from 30 to 40 days to repair the damage to the Lewisburg mines, and this will have a material effect on the coke production of the Alabama company. Byproduct coke oven production shows a slight increase.

Victoria, B. C.

Throughout the four Western Canadian provinces the announcement of Hon. Martin Burrell, Minister of Mines, that a Lignite Utilization Board has been appointed to deal with problems concerned with the further development and use of deposits of lignite coal in this section of the Dominion, has been received with satisfaction by operators. Mr. Burrell states that the action is the result of negotiations between the Provinces of Saskatchewan and Manitoba and the Federal Government, and further asserts that his department has been for a long time engaged in an investigation of the possibilities of carbonizing and briquetting lignite coal for household use as well as for producing byproducts such as ammonia, sulphate and gas. It is explained that the Dominion Government passed an order-in-council some time ago authorizing the Minister of Mines to enter into an agreement with the governments of Manitoba and Saskatchewan providing that they would contribute $100,000 each and the Central Government $200,000, for the establishment of an experimental plant and for investigation and experimental work whether before or after the establishment of the said plant, as might be deemed necessary or advisable. Owing to the absence of the Prime Minister of Manitoba in England, the matter was delayed for a time, but the agreement now has been concluded and the Board appointed R. A. Ross, consulting engineer of Montreal, as its chairman. He has been an active member of the Council for Scientific and Industrial Research and has taken a keen interest in the problems under consideration. J. M. Leamy, of Winnipeg, Man., provincial electrician, and J. A. Shephard, a businessman of Moosejaw, Sask., are the other members.

Anchorage, Alaska

Consideration is being given by high officials of the Administration to the matter of expending the $1,000,000 carried in the naval appropriation bill, for the mining of coal in the Matanuska field for the use of the navy. A press dispatch, under date of Aug. 10, from Seattle, reads as follows: "Secretary of the Interior Lane is negotiating with Secretary of the Navy Daniels, whereby the Interior Department, acting through the Bureau of Mines, may superintend the expenditure of the million-dollar appropriation, carried in the naval appropriation bill, for the mining of coal in the Matanuska coal fields for the benefit of the navy. If Daniels rejects the proposal, the navy bureau of supplies and accounts, at the head of which is Admiral McGowan, will create an organization to produce the coal."

Coal land development in the Nenana field is briefly outlined in a report by Andrew Christensen, head of the Land and Industrial Department of the Alaskan Engineering Commission, who recently made a trip of inspection to the interior country:

"Two parties are developing coal prospects along the line of the Government R.R., in the northern edge of the Nenana coal field," reads Mr. Christensen's report. "One prospect is a 5-ft. bed which was uncovered by the grading contractors at Mile 28, south of Nenana. W. F. Lynn has a free-use permit, and is driving on the bed. Some of the coal was used in a pile driver of the Alaskan Engineering Commission, and proved satisfactory. If the bed continues, and is of proper quality, it is the intention of the Alaskan Engineering Commission to enter into contract with Mr. Lynn for furnishing coal when the railway reaches that point.

"Robert E. Burns and associates have uncovered five coal beds near Mile 50, south of Nenana, on the west side of the Nenana River. These beds lie at a dip of about 45 deg. and appear to be an extension of the large beds exposed on Lignite Creek. They vary from 5 to 20 ft. in thickness, and the quantity of the coal appears to be as good, if not better, than the coal exposed on Lignite Creek. Mr. Burns is driving a tunnel on the largest bed, and is preparing to furnish coal to the railroad when the rails reach it. These beds are located about half a mile above the mouth of Lignite Creek.

"Arrangements will be made to have samples from these mines shipped to the Bureau of Mines Experiment Station, in Fairbanks, and careful analyses made from time to time. It is also planned to install an experimental drier for the purpose of drying the coal so as to improve its efficiency. The principal difficulty with the coal in its raw state is that it slacks rapidly, due to the amount of moisture it contains. Experiment with this coal is being looked forward to with considerable interest, because, if it proves satisfactory, it may be unnecessary to construct a spur across the Nenana River to Lignite Creek at this time in order to secure an ample supply of coal. Coal is badly needed by the railroad, and for domestic use in the interior. Wood is selling at an exceedingly high price, and is becoming rapidly exhausted."

PENNSYLVANIA

Anthracite

Pottsville—The Philadelphia & Reading Coal and Iron Co. has completed 84 model tenements of seven rooms each, electrically lighted, at its Eagle Hill colliery. The houses have ample garden room and rent for $7.50 per month.

Kaska—While the three years' accumulation of water is being pumped from the Kaska shaft of the Alliance Coal Co., the colliery is operating as a washery, loading the banks dumped by the former lessees, the Dodson Coal Co.

Freeland—Three miners employed at the Tomhicken colliery of the Lehigh Valley Coal Co. ran several loaded cars from the outside down the slope, wrecking the hoistway so badly that the mine was idle for nearly a week. When arrested they pleaded that the act was one of mischief and not committed with the intention of hindering production.

Bituminous

Connellsville—Prominent business men of this city did their bit on the coke yards in answer to an appeal by the fuel administration and the H. C. Frick Coke Co. A quantity of coke accumulated on the yards of the corporation's Davidson plant was much needed at the mills and could not be loaded by the workmen without cutting into the regular production. The volunteers—bankers, merchants and business

men—turned out each day for several days and went through a 12-hour shift, stopping only for meals. They were paid regular wages for loading the coke, but the majority of them indorsed their pay checks in favor of the Red Cross.

Pittsburgh—Charged with seeking to hinder coal production in the Pennsylvania fields by purchasing all available supplies of carbide, Charles W. Buck, aged 40, a German, of New York, was arrested on Sept. 6 and is being held for investigation by Federal authorities. It is alleged that Buck made attempts to organize a force of purchasing agents throughout the bituminous coal region of Pennsylvania to buy carbide.

Waynesburg—H. G. Rockwell, of Chicago, Ill., has recently purchased five tracts of coal land in Franklin Township, Greene County, aggregating more than 700 acres, at a uniform price of $400 an acre. A tract containing 333.314 acres was purchased from Judge James Ingram, Mrs. Sarah Lindsey, Mrs. H. D. Patton, of Waynesburg, and the heirs of Elizabeth D. Hook, of Leavenworth, Kan. The consideration was $133,325.60. Two tracts were purchased from I. H. Knox, of Waynesburg, one containing 29.7013 acres and the other 50.012 acres, the consideration being $31,885.32. Two tracts were purchased from J. R. Nutt, of Cleveland, Ohio, one containing 171 acres 107 perches, and the other 174 acres 137 perches. The consideration was $153,706.50.

Savan—Vernon F. Taylor, of Indiana, has sold his Savan mine to E. Walker Smith, of Indiana, and Louis Neil, of Kent. The new owners will continue under the old name of the Savan Colliery Co. The consideration is understood to be $50,000.

Starford—The new mine and tipple of Hetrick & Steward has been put into operation and the shipment of coal has begun. The mine is located on the Cherrytree & Dixonville R. R. and shipment can be made by New York Central or Pennsylvania.

Iselin—The Brown Coal Co. has opened the old Hart mine here and is loading coal over the Lowther Coal Co. tipple near Clarksburg.

Uniontown—An order from the Federal Fuel Administration prohibiting the reclaiming of coke and coal from the breeze dumps after 7 o'clock Monday, Sept. 16, has brought consternation to the many local workers of these dumps. The Fuel Administration believes that man power is better concentrated in straight mining and coke manufacturing. Many thousands of dollars have been invested in this side line and profits have been large.

Connellsville—For the six months ended Aug. 31 Luigi Tucci, 33 years old and single, an Italian miner at Leisenring No. 2, drew down just $1,543.18 in pay. His lowest two weeks' pay check was $106.58, and his largest $146.28. He lost two days' time in the entire half-year stretch.

WEST VIRIGINIA

Logan—Coal is now being shipped from the No. 1 and No. 2 mines of the Jones Coal Land Co. on Dingess Run creek in Logan County.

Fairmont—Among numerous improvements being made at the mines of the Horchler Coal Mining Co. at Hiorra, in the Preston-Monongalia field is the construction of a new boiler house and a new bin for the tipple there.

Kingwood—The Irvona Coal Co. expects in the near future to reopen its No. 1 mine, for which a modern tipple has been constructed. Motor haulage is also one of the improvements just made at this operation, of which D. J. Williams is superintendent.

The work of equipping the mine of the Hoffman Coal Co. has been completed and the company has also built a new office building as well as other buildings usually needed for such an operation.

Charleston—The State Department of Mines will conduct special examinations for mine foremen and bosses at Charleston, Oct. 7-8 and Dec. 9-10, making both examinations on Monday and Tuesday, so that those contemplating taking the examination can travel on Sunday.

Moundsville—Charles Fogle, employed at a local mine, has made a new individual record for loading coal. In one day of eight hours he loaded 30 tons, receiving $18.20 for the day's work. He is 55 years of age and his last 11 days earnings totaled $169.69.

Newburgh—Among numerous improvements made at the plant of the Irvin Coal Co. at this place are the construction of new outside buildings. The company has also equipped its plant with motor haulage as a means of speeding up production.

Dan—The Bradshaw Coal Co. is extending the transmission lines of the Appalachian Power Co. from English, W. Va., to its mines at Dan. The company expects to have power available at the mines by Nov. 1.

INDIANA

Petersburg—The Pike County Coal Co., which operates a mine just east of Petersburg, has increased its capital stock from $100,000 to $250,000 and is enlarging its railroad facilities by building one additional mile of trackage. Hoisting machinery is being put in to increase the capacity of the mine to 4000 tons.

Brazil—The scarcity of coal miners has caused a number of retired miners to return to active work. Permits have been issued by the Clay County miners' examining board, in session in this city, to a number of miners who have been out of active work for three or four years. It is said that there is hardly a mine in the state which is not working short-handed and some of them have lost almost 50 per cent. of their working forces through the draft and volunteer enlistments.

ILLINOIS

Harrisburg—All mines in Saline County have resumed operations after four days of idleness caused by Big Four switchmen quitting work because two roadmen began working in the railroad yards here. Employment was refused 64 switchmen, and new men have been sent to Harrisburg to take their places.

Peoria—Declaring themselves to be 100 per cent. American, more than 300 miners, members of local union 1800, have pledged themselves to produce the greatest tonnage of coal possible to aid in winning the war. This action was taken following the reading of President Wilson's appeal that all energies be directed toward the mining of fuel during the period of the war.

Centralia—Work at the No. 5 mine of the Centralia Coal Co. was resumed after a three-day suspension caused by the miners' dissatisfaction over the discontinuance of the 2 o'clock cage, which is an alleged violation of an agreement between mine officials and the miners. District President McAllister, of DuQuoin, arrived in Centralia to aid in adjusting matters and upon his advice work was resumed. The number of men affected by the three-day cessation was 600, and the loss of coal during the three days' idleness was 7800 tons.

Decatur—The Decatur Coal Co. is asking for an injunction against William Kastner, an employee, and the members of the industrial commission, which ordered the coal company to give him a life pension. The suit is filed by the Employers Liability Insurance Co. for the Decatur Coal Co. On May 27, 1917, Kastner was injured in the mine of the Decatur Coal Co. and in February, 1918, at a hearing before an industrial commission arbitrator, he was given $6 a week allowance for 41 weeks, and a further sum of $6 a week for 175 weeks for the loss of his left leg, injured in the accident. The company was dissatisfied and filed an appeal, the matter being taken to the industrial commission. This commission awarded Kastner $6 a week for 272 weeks and $2.48 for one week. After the 272 weeks period has expired the Decatur Coal Co. is to pay him $10.90 a month as long as he lives. The company now contends that it agreed with Kastner two days before the finding of the industrial commission on a settlement on the basis of the first award and now seeks an injunction to set aside the results of the appeal.

Collinsville—Digging coal is better than being chief of police and water commissioner in Collinsville, Tony Staten, chief of police, and Sam Harrison, water commissioner, have resigned to go back to the mines. They have been getting $100 a month each as officials. They say they can make twice as much as miners.

Benton—T. O. Ratramel has just completed a successful drilling at Dale, near Benton, on the Louisville & Nashville R.R., where he struck a good vein of coal 7 ft. 9 in. thick. Ratramel has a contract to drill down to the lower vein before completing work. Dale and McLeansboro capital is interested, and a $60,000 company has been incorporated to sink a shaft and to operate a mine. A total of 10,000 acres of land has been leased, and a mine will be operated on a royalty basis.

ALABAMA

Lewisburg—The mines of the Alabama Co., which were put out of commission by a cloudburst late the evening of Tuesday, Sept. 5, will not be in a position to resume operations for 30 days or more, pending the repair of extensive damage. John Pennington, contractor, and three negro miners lost their lives in the catastrophe. The work of rescuing the men caught underground following the cloudburst reflects great credit on the officials of the company, C. H. Nesbitt, chief state mine inspector, and others who remained in charge until every man had been removed. A number of large auxiliary pumps are working steadily to clear the mine of water. It is estimated that damage to the mouth of the mine will exceed $15,000, while the loss underground is placed in excess of $10,000. The Lewisburg mines have been in constant operation for 30 years and the output is approximately 1500 tons of coal a day.

Foreign News

Victoria, B. C.—Permission has been granted by George Wilkinson, Chief Inspector of Mines for British Columbia, for the opening of the Jingle Pot coal mine, Vancouver-Nanaimo Coal Mining Co., Ltd., which was ordered sealed ten months ago, owing to the discovery of fire. In the interim the mine has been flooded.

Vancouver Island coal is being utilized by the United States Navy Department on a large scale, the Canadian Collieries (Dunsmuir), Ltd., having entered into a contract to supply as much as can be mined for export. One of the company's officials, in confirming the report, stated that there was no limit to the amount, it being understood that the Navy Department would take as much as could be delivered. Some weeks ago the first cargo of coal under the new arrangement was loaded by a vessel of the United States Shipping Board's fleet at Comox for delivery at the Pearl Harbor Naval Station, Hawaiian Islands. Others have made calls for coal, having a similar destination, and all ships making their base at the Bremerton navy yard will burn Comox coal. This coal, some years ago, was subjected to exhaustive tests as to its suitability for use on American warships and, as a result, the British Columbia production was declared to be almost as good in steaming qualities as the American navy standards.

Personals

Clarence W. Hippard has been appointed research graduate assistant in mining engineering in the University of Illinois. He graduated from the Missouri School of Mines in 1917 with the degree of bachelor of science in mine engineering. From 1909 to 1913 he was engaged in practical coal mining and served one year as assayer for the Stewart Mining Co. at Kellogg, Idaho.

W. E. Seese, of Echo, Penn., has resigned the superintendency of the Black Diamond mines in order to devote his time to several operations of his own in the same locality. Mr. Seese had been superintendent of the Black Diamond operations for about six years.

L. A. Osborn, of Welch, W. V., has succeeded C. L. Biddison as general manager of the Bradshaw Coal Co. at Dan, W. Va.

John Gibson, Jr., of Pittsburgh, Penn., general manager of the Penn Smokeless Coal Co., operating in Somerset County, Pennsylvania, has been commissioned captain of engineers in the army and will leave in ten days for Camp Humphries, near Washington, D. C.

Francis W. Lockhart, of Somerset, Penn., secretary of the Somerset County Coal Operators' Association, has been appointed production manager for that district.

M. M. Broughton, of Connellsville, Penn., superintendent of the Connellsville division of the Baltimore & Ohio R. R., has resigned his position to become connected as a partner in a new coal company.

George Cokely has resigned his position as superintendent of the Tide mines of the Tide Coal Mining Co. near Homer City, Penn.

Frank H. Crockard, for the past year president of the Nova Scotia Steel and Coal Co., has accepted the presidency of the Woodward Iron Co., of Birmingham, Ala.

Obituary

Fred Lesser, mine foreman of the J. S. Wentz Co., Hazlebrook colliery, died recently at the Hazleton Hospital, due to an attack of intestinal trouble.

Trade Catalogs

"The Standard" Scales. The Standard Scale and Supply Co., Pittsburgh, Penn. Catalog A.235. Pp. 48; 8½ x 11 in.; illustrated. The scales described and illustrated in this handsomely printed catalog include those that will weigh anything from a small package to a carload of coal. A telegraphic code and comprehensive index is included.

Industrial News

Louisville, Ky.—The Mountain Gem Coal Mining Co. has filed amended articles authorizing an increase in the capital stock from $10,000 to $20,000.

Jacksboro, Tenn.—The Smith Blue Gem Coal Co., capital $4000, has been incorporated by A. W. Smith, Jr., R. Y. Gray, Jr., Jay Lindsay and others.

Youngstown, Ohio—The United States Railroad Administration has authorized the construction of the 5½ mile railroad required to connect the coal property of the Youngstown Sheet and Tube Co. in southwestern Pennsylvania with the steam carrier serving that territory.

Charleston, W. Va.—Suit has been instituted by the New River Co. and by the other companies operating in the same section against the Virginian Power Co. for $150,000 for damages for failure to furnish power to operate the mines in the territory covered by the power company.

Frontenac, Kan.—Two or three coal mining plants will be erected by the Jackson-Walker Coal Co. at an expenditure of $25,000. It is reported that the material needed will include belts, boilers, cages, cars, concrete, conveyors, hoists, lumber and track for inside and outside the mines.

Cleveland, Ohio—The Jeffrey Manufacturing Co., of Columbus, Ohio, has reopened its branch office at 437 Leader-News Building. P. C. Dierdorff and C. B. Reed, who have had years of experience in the solving of elevating, conveying, crushing and mining machinery problems, will be in charge.

Arma, Kan.—The Central Coal and Coke Co. will start work about Oct. 1 on the opening of two mines, each to cost in the neighborhood of $25,000. The material and equipment not yet purchased includes lumber, roofing, engine, boilers, hoists, screens, conveyors, belts, concrete mill and hardware.

Pittsburg, Kan.—Work will be started Oct. 1 on the coal mining plant of the Machie-Clemens Co. D. W. Jones, the superintendent in charge, states that about $25,000 will be expended. Some of the material and equipment not yet ordered comprises belts, boilers, cages, car loading device, coal cars, conveyors, hoists, lumber, etc.

Cleveland, Ohio—To facilitate the handling of its mine hoist business, the Ridgerwood Manufacturing Co. has opened a branch office in the Union National Bank Building. Ernest F. Pegg, who until recently was associated with the W. M. Pattison Supply Co., former selling agent for the Lidgerwood Company, will be in charge of the new office.

Milwaukee, Wis.—Six steel cranes (Brownhoists) formerly used by the Milwaukee Western Fuel Co. have been commandeered by the Government and will be dismantled and shipped to war plants in the East. The cranes originally cost $125,000, but at the present price of materials and labor it is said they could not be constructed for less than $500,000.

St. Louis, Mo.—Barge service for coal and other freight will be inaugurated on the Mississippi and Black Warrior rivers on Sept. 28. At 5 p. m. that day a fleet of seven towboats and 30 barges will leave St. Louis for the first trip down the river. According to announcement stops will be made only at the cities which have provided suitable docking facilities.

Washington, D. C.—The Interstate Commerce Commission was asked recently by the Western Trunk Line Committee of Chicago, representing 30 railroads, some of which are not under federal control, to grant an increase of freight rates on interline shipments of bituminous coal so that the rate on non-controlled lines will be the same as on Federal controlled lines.

Indianapolis, Ind.—It is believed that the production of 2,886,422 tons of coal during the month of August has established a new record in the hoisting of coal by Hoosier mines. The record of July, 2,865,163 tons, has been exceeded by the August production. This new record has been established in spite of the fact that work in the Knox County mining fields was hindered for several days on account of a shortage of cars.

Indianapolis, Ind—A total of 12,000 additional tons of coal mined in Indiana will be delivered daily to the number of railroad lines to make up in part for the portion of the railroads' supply of coal taken over by the Government officials for use in navy and transport work. The daily average of Indiana coal used by the railroads has been 18,000 tons during the recent weeks and this amount will now be raised to 30,000 tons of coal daily.

Pittsburg, Kan.—The Western Coal Co., which has started work on the development of its coal property at Franklin, Kan., expects to be ready to ship coal by the latter part of November. About $25,000 is to be expended on lumber, concrete, hoists, wire cable, engine, boilers, belts, pumps, roofing, coal cars, tracks, conveyors, screens, pipe, etc. It is understood that none of this equipment and material has been purchased. Philip Rayer is superintendent in charge.

St. Louis, Mo.—Coal is to be stored in the streets of St. Louis if there is not room enough elsewhere. Fuel Administrator Crossley has ordered the St. Louis Board of Public Service to issue a permit to the Monsanto Chemical Co. for the use of Geyer Ave. east of Second St. for that purpose. The company has not adequate storage facilities without using the street. It is engaged on war contracts. This is the first time that the use of a street for that purpose has been allowed.

Whitesburg, Ky.—The Elkhorn & Jellico Coal Co., which was incorporated in July, has been organized with M. K. Marlowe as president and general manager; H. L. McGhee, vice president; P. E. Marlowe, secretary; and James A. Marlowe, treasurer. The company has 550 acres of coal land to develop, and has leased other lands and proposes development of a townsite, etc. The company is capitalized at $500,000 and plans immediate development, having started placing inquiries for mine cars and equipment.

Birmingham, Ala.—Motor truck transportation of coal on an extensive scale is being projected by the Birmingham Civil Association, working in conjunction with the County Board of Revenue and the Board of City Commissioners. A contract has been made with the Jenkins Motor Co. to establish two motor lines within the next 30 days capable of moving 200 tons of coal daily. Plans have been perfected for the establishment of a municipal coal yard to supply domestic trade as soon as the movement of coal starts.

Fairmont, W. Va.—Team-track loaders in the Fairmont district, which includes 12½ counties of West Virginia, are back on their old basis. The plan of D. R. Lawson, district representative, to have all wagon-mine coal consigned to the Fuel Administration at the scales at Keyser proved unwise and resulted in a congestion of box cars of coal. Mr. Lawson called team-track loaders together and explained the situation, putting it in such a light as to win their interest for the report system, which wagon-mine operators had not taken seriously up to this time.

Toledo, Ohio—Considerable activity was shown at the Toledo docks in loading lake coal during the week ending Sept. 7. This activity is taken as an indication that the lake quota will be made up unless some untoward event occurs. The Hocking Valley docks loaded 227,252 tons during the week as compared with 180,878 tons during the previous week, making a total of 3,089,542 tons for the season. The Toledo & Ohio Central docks loaded 66,000 tons as compared with 81,000 tons the previous week, making a total of 1,357,000 tons for the season.

Wellsburg, W. Va.—The Electric Mining Co., of Wheeling, a $1,000,000 corporation, has been granted a charter in Charleston to operate mining interests in Brooke County. The company a short time ago acquired control of the J. V. Thompson Coal interests, and one of the most modern mines in West Virginia will be put in operation within a short time. About $550,000 will be expended for machinery, etc. Stockholders include R. E. Breed and H. L. Montgomery, New York; H. L. Finley, Brooklyn; George N. Tidd, Elizabeth, N. J., and Frank B. Ball, Plainfield, N. J.

Harrisburg, Penn.—John T. Dempsey, president of the Miners Union in District No. 1, and Samuel J. Jennings, assistant to the president of the West End and Price-Pancoast coal companies, were on Sept. 12 named additional members of the board of appeals for the middle district of Pennsylvania, division No. 1, with headquarters in Scranton. The appointment of Mr. Dempsey and Mr. Jennings will give the miners' union and the coal industry three men on the board, the other being Thomas Davis, of Nanticoke, who is an international executive board member of the union.

Lexington, Ky.—The May Branch Coal Co., of Lexington, has been reorganized through filing amended articles of incorporation in which the name of the company is changed to the White Ash Fuel Co., while the capital stock is increased from $25,000 to $75,000, and arrangements made for opening a branch office at White Ash, where the company has mines. John W. Masner, W. M. Parrish and James T. Garey, of Lexington, are directors and officials of the company. The amended articles allow the company to deal in timber, coal and mineral lands, and sell the products of such lands.

Frankfort, Ky.—The Secretary of State has handled the following new corporations charters or amendments within the past few days: Blackey Coal Co., Letcher County, increasing capital from $3000 to $40,000. East Kentucky Coal Co., Perry, increasing capital from $25,000 to $50,000. Redwine Cannel Coal Co., Morgan County, increasing capital from $2000 to $10,000. Bruner Coal Co., Manchester, Ky., capital $500; incorporators, G. C. Hibbard, Gertrude Hibbard and G. B. Bruner. Lackey Colleries Co., Ashland, Ky., capital $10,000, R. D. Clere, Myrtle Dennis and E. E. Seaton. Upper Harlan Coal Co., Harlan, increasing capital from $60,000 to $100,000.

St. Louis, Mo.—The recent action of the St. Louis Fuel Committee in ordering a reduction in the price of coke from $13 to $11.25 a ton has been confirmed by Federal Administrator Garfield. When the price was fixed by the St. Louis committee Aug. 6, the coke distributors balked and continued to do business on the basis of $13 a ton. Meetings were held but no settlement was arrived at. The matter was referred to Garfield and he summoned the parties to Washington. The committee was represented by Advisor E. J. Wallace and C. E. Morrow. The reduced price was ordered enforced as of date Aug. 28. Retailers who have purchased on the basis of the higher price will be reimbursed $1.75.

Charleston, W. Va.—The necessary sanction to install sidings having been secured from the Fuel Administration, the Newcourt Coal Co., with an authorized capital of $100,000, will at once proceed to develop a lease of 1300 acres in the Black Band seam, near Brounland, on Brier Creek, in the Coal River section, tests showing a thickness of from 43 to 54 in. in the coal. A modern tipple will be constructed, and when the plant which is to be electrically equipped is ready for operation, it is estimated that the capacity of the plant will be at least 200 tons a day, and later from 500 to 1000 tons a day. W. J. Newenham, formerly of the Pocahontas Consolidated Collieries Co. and of the H. C. Frick Coke Co., has been made president of the new company, with T. E. Courtney, of Charleston, as secretary-treasurer.

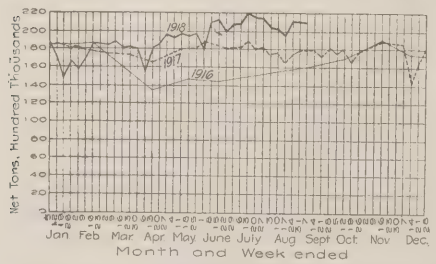
Pittsburgh, Penn.—Nine large coal operations in western Pennsylvania, southern Ohio and West Virginia, which were originally purchased by John H. Jones, have been taken over by the Consumers Fuel Co., a Pennsylvania corporation. This company, and the Consolidated Fuel Co. an Ohio corporation with which it is closely allied, have a combined capitalization of nearly $4,000,000. The two organizations are now producing yearly 2,000,000 tons of steam, gas and byproduct coal, and expect to increase the production ultimately to 4,000,000 tons a year. Mr. Jones is retained in charge of production. The companies merged include the Miners Block Coal Co., the Maple Hocking Coal Co., the Goucher Mine Co., the Miners Coöperative Co., the Louise Coal Co., the Quality Cement Coal Co., and the Rachel Gas Coal Co.

MARKET DEPARTMENT

Weekly Review

Labor Day Cuts Into Coal Production—Many Miners Made Up Holiday by Working Extra Time—Soft Coal 17,000,000 Net Tons Behind Schedule—Anthracite Output Ahead of Last Year—No Change in Market Conditions

AS was to be expected, the observance of the Labor Day holiday throughout the mining regions cut into the production of both anthracite and bituminous coal during the week ended Sept. 7. Bituminous output totalled 11,249,000 net tons for the week (5⅓ days), while anthracite shipments for the same period amounted to 1,617,579 net tons.



It should be recorded, however, that the miners at quite a few operations made up for the holiday by working extra time the Saturday preceding, and another fact which should be emphasized is that the percentage of absenteeism the day following the holiday was negligible. Appeals to the miners for more regular working time are undoubtedly having their effect.

Bituminous coal output is now approximately 17,000,000 net tons behind schedule, and production for the rest of the coal year must be maintained at the rate of 2,041,000 net tons a day if the deficit is to be made up. The car supply is now excellent, however, and the bituminous mines have everything in their favor for a drive on greater output. Anthracite production for the coal year to date is estimated at 45,645,597 net tons, which is an increase of 1,084,000 net tons over the same period of last year.

Market conditions present no radical changes. The Fuel Administration has the distribution and allotment of all grades of coal well under control, and a determined effort is being made to supply the Northwest before navigation on the lakes closes for the season. Dealers have many unfilled orders on their books, but the total quantity of coal delivered to domestic consumers to date is far greater than was true at this time last year. Conservation, diligently practiced, will be necessary, however, to avert a shortage this year.

WEEKLY COAL PRODUCTION

Production of bituminous coal during the week of Sept. 7, while limited by the loss of time on Labor Day, exceeded production during the week of July 6 when production was also limited 1,000,000 net tons by a holiday. The output during the current week (including lignite and coal made into coke), is estimated at 11,249,000 net tons, a decrease compared with the week preceding of 1,455,000 net tons or 11.5 per cent. and an increase over the corresponding week of last year by 1,257,000 net tons or 11.2 per cent. The average production per working day during the week of Sept. 7 (5⅓ days), is estimated at 2,110,000 net tons as against 2,117,000 net tons during the week of Aug. 31 and as against 1,874,000 net tons during the same week of 1917. The loss of time during the current week places production for the coal year to date approximately 17,000,000 tons behind the summer requirements outlined by the Fuel

Administration and makes necessary an average daily production during the balance of the coal year of 2,041,000 net tons to make up this deficit. This, it will be noted, is 3.2 per cent. in excess of the average daily production for the coal year to date.

Production of anthracite during the week ended Sept. 7 is estimated at 1,617,579 net tons, 28 per cent. less than the production during the week preceding, due mainly to loss of time on Labor Day, and 3 per cent. less than the corresponding week of last year. The daily average during the week of Sept. 7 is estimated at 323,516 net tons as against 338,111 net tons during the coal year to date and as against the daily average of 330,081 net tons during the corresponding period of 1917. The total production for the coal year to date is estimated at 45,645,597 net tons, an increase over the same period of last year of 2.4 per cent.

Shipments of bituminous coal, during the week of Sept. 7, decreased from all districts with the exception of Southwest Virginia, where the increase was slight and amounted to approximately 1 per cent. Material decreases were reported in central Pennsylvania where shipments amounted to 32,122 carloads against 36,724 carloads during the week of Aug. 31, from western Pennsylvania, where shipments amounted to 9098 as against 12,048 carloads; from Ohio, where shipments amounted to 22,545 carloads as against 26,942 carloads; and from the districts including Illinois, Indiana and western Kentucky, where shipments amounted to 44,085 carloads as against 49,614 carloads; and from the district including Iowa, Texas and western states, where shipments amounted to 12,632 carloads, as against 15,603 carloads. Compared with the corresponding week of 1917, all districts, with the exception of Michigan, report considerable improvement.

A considerable decrease occurred in dumpings at lake ports during the week ended Sept. 8. The tonnage dumped during this week (including bunker coal), is estimated at 1,012,297 net tons, a decrease compared with the week preceding of 13 per cent. and with the weekly average during July, August and September of 3 per cent.

Shipments of bituminous coal to New England during the week ended Sept. 7 are estimated at 574,194 net tons as against 604,158 net tons during the week preceding, or a decrease of 5 per cent. Compared with the weekly average for the coal year to date, shipments during the current week were approximately 3 per cent. higher. Rail receipts through New England gateways during the week of the 7th are estimated at 226,130 net tons, slightly in excess of the receipts during the week preceding and the weekly average. Tidewater shipments, amounting to 348,064 net tons, while approximately 10 per cent below the shipments during the week of Aug. 31, are slightly in excess of the weekly average. Shipments during the week declined from all harbors with the exception of Baltimore, from which harbor shipments increased 6.5 per cent. while shipments from New York and Philadelphia decreased 22.3 per cent. and from Hampton Roads 8.3 per cent.

Shipments of bituminous coal during the week ended Sept. 7 not only fell below the shipments during the week preceding, but also below the weekly average for the coal year to date. Shipments from North Atlantic ports and Hampton Roads are estimated at 895,278 net tons, all harbors falling behind the performance of the week preceding. Shipments from New York and Philadelphia decreased 6 per cent. from Baltimore, 0.6 per cent. and from Hampton Roads, 1.8 per cent.

Production of beehive coke in the United States during the week ended Sept. 7 is estimated at 616,000 net tons as against 608,000 net tons during the week preceding, or an increase of approximately 2 per cent. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production for the week ended Sept. 7 at 390,010 net tons and the operation of their plants at 76.2 per cent. of present capacity. Yard labor shortage was slightly greater than during the week preceding, but such loss was offset by causes not reported.

Operating conditions in the byproduct industry improved slightly during the week ended Sept. 7, such slight improvement being attributed by the operators to a better supply of byproduct coal. The plants of the country were operated during the current week at 90.6 per cent. of their present capacity, shortage of byproduct coal causing a loss of present capacity of 2.5 per cent., labor trouble 1.5 per cent., repairs to plants 4.1 per cent, and all other causes 1.3 per cent. Material improvement occurred in Illinois, Kentucky, Maryland and Pennsylvania. In Illinois the improvement is attributed to a better supply of byproduct coal, in Kentucky to repaired plants, and in Maryland and Pennsylvania to better labor conditions. Tennessee was the lone state reporting material decrease during the week, the cause not being reported. Increased capacity of Illinois plants during the week was brought about by an increase at the Semet-Solvay Co.'s plants at South Chicago, Ill.

BUSINESS OPINIONS

Marshall Field & Co.—Current shipments were largely ahead of the corresponding week of a year ago. Road sales for immediate and spring delivery also showed an increase. Not quite so many customers were in the house compared with the similar period of 1917. Collections continue excellent.

Bradstreet's—Insistent demand for war materials, the return of confidence in previously drought-stricken areas, indications of a heavily increased winter-wheat acreage, a record movement of grain, high prices for all farm products, and the certainty that orders offering are far larger than supplies, stand out as the prominent features of this week's news. Widespread rains putting the soil generally in good condition for a record winter-wheat seeding, some improvement in cotton and corn that had not been injured beyond repair, and unprecedentedly high prices for all kinds of farm produce and meat-producing animals, have removed some of the hesitation shown in the southern and southwestern sections.

American Wool and Cotton Reporter—There is just as much uncertainty as there was some time ago in regard to the available supply of raw wools. Until the maximum army has been developed, it is quite

likely that a conservative policy will be followed in regard to letting out wool for civilian fabric production. Some hope that better conditions will come about is held out through a possible agreement as to raw material supply for all of the allies, and by the increased purchasing of South American wool by the commission handling this portion of the problem. In the cotton market it is thought that with the scarcity of money the banks in the South are not going to be so lenient as previously. For this reason, it will be necessary for many of the Southern farmers to sell their cotton. This ought to be felt fairly extensively and should reduce the price of futures on the exchange when the movement takes place.

The Iron Age—The vast scale of the plans for the offensive in France appears in weekly calls for more steel. The distribution of 34,000 tons of barb wire for the Government is just completed, with 22,000 tons for France in abeyance, when larger war demands for this product came up than have been considered at any time thus far. In the Cleveland district, the placing of 10,000,000 additional shell forgings is one indication of the tremendous recent enlargement of the munitions program. The ordinary consumer's chance of getting steel, judged solely by the developments of the past week, will grow steadily less in the final quarter of the year. Some letting down of demand may come in the structural field. Probably all the fabricated ship work for next year has been contracted for, and it is expected that all essential work will be let before 1919, with a total that will not keep the monthly volume of awards to the 60 to 65 per cent. of capacity that has been the rule so far this year. The poor financial showing of the railroads may rule out much railroad bridge work that earlier was thought certain.

Atlantic Seaboard

BOSTON

Diminished receipts already noticeable. Hampton Roads loading continues slow. Baltimore dispatch not improved. Byproduct and railroad fuel tonnages readjusted. Movement slackens all along the line. Long lists of consignees embargoed from central Pennsylvania. Rail movement falls off slightly, but full effect of embargoes not yet felt. Box cars come forward in volume, mainly to New England, although number is expected to be cut down. Several steamers withdrawn from coastwise coal service, but more due from the lakes. Fires in railroad storage interfere with receipts. Connecticut an area that needs coal. Movement to New York piers not yet sufficiently increased. Baltimore & Ohio movement reduced. Anthracite shipments also sag slightly. Average daily receipts at gateways less than in any month since February. No change as yet in retail prices.

Bituminous—The trade is beginning to realize that already coal is coming forward in less volume to New England. Instead of the harbor being congested with ships, so far as unloading facilities were concerned, there was actual inquiry this week for spot cargoes. A week ago it was next to impossible to comply with the Washington ruling as to permissible stocks and still free cargoes that were waiting to be discharged. It is felt that the visit here last week of J. D. A. Morrow, of the United States Fuel Administration, contributed a great deal to a better understanding on the part of Washington as to the actual situation here, and it is likely there will be a more evenly managed distribution, especially with regard to Hampton Roads. Close observers seem to be agreed that another ten days will see the New England situation materially changed as to current receipts. Both by water and rail there are influences at work that will undoubtedly reduce flow of coal this way. Fuel authorities here are keeping close watch of local conditions and where a plant is found to have an undue supply on hand the fact is promptly reported. On the other hand, if it is found that a plant should not have had coal shut off at the source, the mistake is promptly rectified.

Loading at the Virginia terminal continues slow and causes much anxiety to New England consumers who are counted upon to pay the demurrage bills. The tonnage of bottoms waiting is still far in excess of coal available, and it is probable that this will continue indefinitely or until the number of bottoms is reduced to a really considerable extent. More and more of the modern type of collier, self-trimming and of fair speed, will be taken for oversea work as the season advances and requirements for supply service are increased. The Inter-Allied Shipping Board is watching this situation carefully.

Baltimore dispatch varies from Hampton Roads only because less tonnage is involved. The flow of coal has slackened materially, but steamers are still being entered to load. It is not that the coal is moving to the New York piers rather than to Curtis Bay, but that more is being ordered west and to plants along the line.

District representatives and others have been engaged now for more than a week in readjusting tonnages for railroad fuel and for byproduct use. Government requisitions for byproduct plants have enormously increased the last few weeks, and to meet these some radical cuts have had to be made in other directions.

Railroad fuel receipts are about the same, although due for an increase soon. The average for 12 days in September for bituminous at the five gateways, commercial coal and railroad fuel together, was 708 cars, or less than the average in March, 1918. Particularly is this cut in receipts noticed in the last few days, the average of which would be 50 cars less per day. It is another sign of the decreased shipments that prevail or are soon to prevail in all quarters. It is likely that September as a whole will show a very marked reduction in New England receipts, especially where the full effect of embargoes is evident.

Wagon-loaded coal continues to come forward in volume, and practically 80 per cent. of that from the central Pennsylvania district comes to New England. Early in July this coal was most welcome to New England and the fuel authorities have been grateful for the extra volume of coal this has meant. Everything has been done in the way of prompt payments, etc., to make shippers feel the coal was being put to good use, but latterly it has become increasingly difficult to find consignments for the whole 600 cars per week. Labor is scarce, the railroad authorities are constantly complaining of delays in unloading, and the inferior quality of much of the coal have all been against a growing tonnage. The result is that for the next few weeks New England will hardly be in position to take more than half what was readily absorbed a few weeks ago.

Colliers, in tonnage amounting to approximately 90,000 tons, have been released from the trade and are now being made ready for general cargo use to France. Most of these were ships not well adapted to coal carrying, although some were built for this trade. The latter will doubtless be requisitioned as colliers, to help meet the demand for coal overseas.

Perhaps the one area in New England where reserves are less than the Washington rule allows is Connecticut. Industries in that state have not had the advantage of the increased movement of steamers because there are no ports where such ships could unload. In fact, the increased volume of coal for Curtis Bay, Baltimore, meant reduced shipments to the New York piers and these have not yet been built up to a point where cargoes could be regularly loaded for points on Long Island Sound where the need is greatest.

Anthracite—Receipts of domestic sizes both all-rail and by water have also sagged the past fortnight. The average number of cars per day at the New England gateways for 12 days in August was 452. Some of the days recently the movement has fallen below the mark for any week since February. Receipts of anthracite screenings remain fairly stable, although practically all this coal is moving on old contracts.

No change has yet been made in retail prices to affect the recent 30c. advance. Dealers are hard put to it to make deliveries in sufficient volume. Some retailers are making an effort to deliver at least one ton on each requisition on file.

NEW YORK

Dumpings of anthracite at the local docks show a decrease, but dealers are kept busy. Conservation of fuel urged by Fuel Administrators if serious shortage is to be averted this winter. Producers directed to increase shipments to certain localities. Bituminous market in better condition than it was a year ago. Demand continues heavy.

Anthracite—Reports of heavy production and shipments from the anthracite fields cannot be said to be reflected in receipts here. While shippers and dealers are not gloomy as to what conditions might be next winter, they are not over-enthusiastic as to the prospects. They confess to handling an unusual amount of coal this summer and the retail dealers admit having placed a heavier tonnage than usual; still they say that more coal must be sent to this market if serious conditions are to be averted. One shipper who handles a heavy tonnage, especially through New England, probably voiced the opinion of most members of the trade similarly situated, when he said, in reply to a question concerning trade conditions: "We are just holding on."

Urging conservation of fuel several statements were issued from the offices of the local Fuel Administrators last week. One of these limited the amount of coal to be delivered to consumers until other consumers have received a portion of their winter's supply.

Receipts here are reflected in the number of cars of anthracite dumped at the local docks. For the seven-day period ending Sept. 13, this amounted to 6635 cars as against 6719 cars for the week ending Sept. 6, a decrease of 84 cars.

There has been no relative change in the positions of the domestic coals. Demand for each is about evenly divided, stove being the shortest. The steam coals are differently situated. Buckwheat No. 1 is long, rice moves slowly, and barley of which there was an overabundance a few weeks ago, is short with some of the large producers.

The retail situation is active. While the dealers are not getting all the coal they would like they are kept busy because of the lack of labor. They admit putting considerable more coal in consumers' bins than usual, but their orders are far from being cleaned up. In the Bronx the dealers have fixed upon a week in October as a time to make a clean-up of one or two ton orders.

E. E. Hawkins, Jr., Fuel Administrator for Suffolk County, Long Island, has announced the allotments of domestic sizes of anthracite for the various towns and cities of that county for the fall and winter, and also the maximum prices allowed for the various grades of coal. The prices average about $1 a ton higher than those of the April to September schedule and range from $10.05 to $10.55 for broken and egg sizes; from $10.30 to $10.75 for stove and chestnut, and from $9.40 to $10 for pea coal, the variations in prices being based on transportation charges. The allotment is 189,604 gross tons, not including the tonnage needed in Camp Upton. Mr. Hawkins believes that with economy there will be sufficient coal to go around. No coal is allowed for houses opened only part time, such as summer residences which it has been the owners' custom to visit occasionally in winter. The supply is cut for commercial greenhouses to half of demands, and none is allowed for private greenhouses.

Current quotations, per gross tons, f.o.b., tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea..... 5.50	6.25		

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—The bituminous situation continues to move slowly, with comparatively little tonnage moving compared with the demand. While some consumers have large stocks on hand others have barely enough to keep their furnaces going. However, the situation as a whole is better than it was at this time last year.

Efforts are being made to secure a modification of the order of Aug. 2 fixing a maximum storage period, and already nearby New Jersey manufacturers believe they will be able to secure an increase of storage time from 30 to 60 days. After argument by the committee representing the New Jersey manufacturers it is said consent was given whereby that State is allowed an extra supply of coal on tidewater deliveries.

There was an improvement in the dumpings at the local docks during the week ending Sept. 13. 7630 cars of bituminous having been dumped as against 6823 cars dumped the previous week, an increase of 807 cars. Much of this coal was sent, however, to New England and Long Island Sound points, with the result that local dealers did not reap much benefit.

The bunker situation is looming up again. Because of the vast number of vessels continually in the harbor demands for this grade of coal are heavy and shippers are sometimes hard pressed, but so far there has been no delay in loading.

There is enough of the ordinary grades of coal to go around, but spot buyers can-

not be supplied, free coals not being obtainable.

This is due in part to the shipping by nearly every operator, on orders from Washington, of a substantial part of his output, leaving the balance for his old customers.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite trade stirred by cool weather. Customers complain of distribution. New allotment figures given out. Shipments show falling off. Operators hopeful as to future. Criticism as to retail prices. Steam sizes show some easing off. Little demand for culm. Bituminous helped by improved car supply. Distribution plans working well. Brokers easier.

Anthracite — Cool weather brought trouble for all dealers. They were besieged by their customers, for few seem to be satisfied. Those who have had no portion of their orders delivered insisted on a few tons immediately, while the more fortunate, whose coal bins are partly filled, demanded the balance due. The dealers were kept busy explaining how impossible it is for them to care for a year's business in six months.

A number of representative dealers have recently expressed regrets for not having distributed their receipts of coal differently. They claim they would be in a better position today if they had received only a few tons on every order received. Then all their customers would be in shape to at least start their fires when necessary. In giving the full two-thirds to many of their larger buyers, who as a rule are the most impatient, they have not only failed to satisfy them but they have been forced entirely to neglect many small orders. The same conditions prevail in the suburban sections.

This week the anthracite committee gave out the long awaited new allotment figures based on an increase of 18 per cent. over the basic year of 1916-17. This list covered every community in the state entitled to anthracite coal, as it will be recalled that thirty counties by a previous ruling are not to receive any anthracite. For this city the increase amounted to 451,155 tons, or a total of 2,800,000 tons. While the trade was satisfied in a way that the figures had at last been given out, yet there is a feeling that they would rather have shipments than estimates of what they are expected to receive. Coincident with this announcement shipments seem to have experienced a decided falling off. The shipping companies are advising their trade that New England territory is again receiving preferred treatment.

There has been considerable newspaper agitation about the difference in the retail rates as charged by the different dealers. It seems that some dealers are in a general way accused of charging higher prices than allowed by law. This is due to the two different wholesale prices adopted for the company and individual product, and there seems to be little possibility of correcting the evil while the Government allows the so-called independent operator to charge 75c. above company prices, with an additional 20c. when sold through brokers. Some dealers have coal coming from all shippers and middle houses and as they are expected to establish new rates every two weeks based on the average price paid the 15 days previous, it is an almost hopeless task for the fuel administrator to keep a strict check upon them. Investigation shows the dealers who buy most of their coal from the big companies are selling far below the dealer who is chiefly supplied by the smaller houses. We are inclined to believe the representative houses are well within their rights and if there is any abuse it is among a class who handle very little coal.

The retailers are meeting little success as yet in breaking down their customers' preference as to sizes. Certain it is that those buyers who are the least particular in this respect are the ones who are getting the best service these days. While the buyers still indicate their preference for stove and nut, it makes no difference in the dealer's demand upon his shipper for coal of any size. For this reason there is some slight accumulation of egg, as well as a slight increase shown in the quantity of pea, in the bins, but the stocks of even these sizes are not of sufficient volume to cause any comment.

The fuel authorities are continuing their efforts at conserving every possible ton of coal and have now issued an edict that no club in the city shall have more than a week's supply of coal on hand at a time. They are also further restricted in that they will be ordered to close their buildings at 11 p.m. when the cold weather comes.

There is just the slightest easing off in the steam trade. This is perhaps only noticeable to the largest producers and is even indicated in buckwheat with them. Not that this size is in actual surplus, but they are having less trouble in filling their pressing requisitions. With one company handling a special grade they were actually looking for increased business on it and notified some of their choice trade that they could possibly accommodate them with a few hundred, or even a thousand, tons. Very often, however, the exemption law on this size causes trouble. It was reported on rice that some of the big shippers could actually handle some new business, although they did not go after it. With culm the activity seems to have almost ceased for the time being and no particular demand is now looked for until winter is well upon us.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—There is something of a changed tone in the bituminous situation. Most operators are reporting a better car allotment, although disappointment is expressed at the inability to keep sufficient labor on hand at times to load the cars. The distribution of coal to the smaller war plants, as well as some of the non-war industries, is progressing satisfactorily. The plan of giving the former at least a 30-day supply and the latter 15 days seems to meet with favor, although the larger concerns are somewhat anxious now that they are not receiving storage coal in the volume they have been accustomed to all summer long. Some of the larger concerns have had trouble during the previous month with spontaneous fires and this as much as anything led the distribution committee to make the change, as their attention was in this way directed to the large quantities which they had accumulated.

The brokerage trade is also somewhat brighter, as with the increasing car supply they have been able to handle a better tonnage than for some time back. Of course there is no solicitation on their part to dispose of this coal, as they all have standing orders that would take many times the quantity they are able to procure. It is now a settled practice for at least the smaller houses to keep a representative in the region gathering in coal.

BALTIMORE

Good tonnage flow of bituminous continues, and there is a betterment noted in grade. Still room for improvement, however. Anthracite tonnage for August disappointing. Prices go up 40c. retail.

Bituminous—A fairly liberal tonnage flow continues here. Because of the fact that quite a number of industries, well supplied under priority deliveries in the months past, are temporarily off the supply list, the distribution here in some cases has been liberal enough to allow stocking up in some measure by industries that had been living virtually from hand to mouth on fuel needs. Following some rather strenuous complaints, including one of an ice company that was shut down because it could not maintain steam with the kind of coal supplied through the local administrator, the district representative promised a better flow, at least in part, and some little improvement is already noted. There is room for improvement, however. This bad coal is not only confined to the all-rail business, which is largely in box cars, but to the open-top car deliveries at the tidewater pool. Most of the coal that comes to the pool for local delivery over the piers is poor, and the condition was so marked that two pools of fair grade coals were recently abolished and all the fuel turned into Pool 18, which has always been a poor grade section and disdained by most industries in ordinary times. Two other better pools here are practically out of the market also because their coals are now going exclusively for railroad fuel purposes. The balance of the coal coming through is under Government control.

Anthracite—Figures just given out here of August tonnage of hard coal prove the dissapointment of the dealers, who had been led to hope that the month would see a big spurt to make up for the deficiencies in shipments in April, May, June and July. The tonnage indeed fell below all those months with the exception of July. During the month a total of but 50,750 tons was received. The tonnage on hand the previous month was 16,948 tons as compiled by dealers here. The tons delivered by dealers totaled 37,582, and the undelivered tonnage on books of retailers at the start of September was 199,245 tons. When it is stated that Baltimore has been allotted 713,318 tons, on a claim of needs around 850,000, and has up to Sept. 1 of this coal year received but 281,725 tons, the seriousness of the situation here can be judged.

Under order of the Maryland Fuel Administrator retail prices here on Sept. 9 were advanced 40c. a ton on all grades except broken and buckwheat. Thirty cents of the advance is represented in the wholesale advance and 10c. is allowed retailers to cover their claim that they should get at least 20c. a ton additional to care for added overhead charges on operation. The new schedule of prices is as follows:

	Ton	Half Ton
White Ash:		
No. 1 (broken)	$10.85	$5.60
No. 2 (egg)	10.85	5.60
No. 3 (stove)	11.10	5.70
No. 4 (chestnut)	11.20	5.75
Pea	9.35	4.85
Buckwheat	8.60	4.45
Lykens Valley:		
No. 2 (egg)	11.55	5.95
No. 3 (stove)	11.95	6.15

Lake Markets

PITTSBURGH

Mr. McAdoo brings coal production manager and director of steel supply together. Lake shipments still behind program.

The Director General of Railroads, who represents one of numerous Government activities that are steadily pressing the War Industries Board for larger supplies of steel, was in Pittsburgh last week. Mr. McAdoo refused to go into details, for publication, as to what was being done or is contemplated in the matter of railroad rehabilitation against the coming winter, but indicated that no extensive work along the line of additional trackage was contemplated for the Pittsburgh district. A significant item, however, was that he summoned to meet him in Pittsburgh, A. W. Calloway, manager of bituminous coal production for the Fuel Administration, who wants Mr. McAdoo to give him more transportation, and J. Leonard Replogle, Director of Steel Supply, whom Mr. McAdoo wants to furnish more steel for railroads. What transpired is not known, but that the representations made were interesting cannot be doubted. It is just learned that Mr. McAdoo has lately been calling for a supply of 60,000 tons of rails a week until further notice, rails to be laid in the north while weather permits, and then in the south. Steel men assert that such a tonnage cannot possibly be furnished, but the supply in the past few weeks has been much larger than formerly.

Lake shipments of coal continue decidedly short of the program and it will undoubtedly be necessary to continue shipping after Oct. 15, the date on which the program is based, and this will correspondingly reduce the interim period during which it was expected that byproduct coke plants and other important coal consumers would be able to stock up against the winter. The responsibility of the railroads by way of maintaining transportation in the winter is therefore increased. By paying close attention to the preference list of coal consumers the distribution of coal is fairly satisfactory with respect to current consumption.

The market as such is without incident, there being little movement except by way of allocations. Set prices remain: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to be charged consumers by regular brokers.

BUFFALO

Trade much more tranquil than formerly. Indications of better supply. A little more anthracite now. Lake shipments in larger amount, though behind last season.

Bituminous—Somehow the general idea is that the supply is better than has formerly been supposed. Statistics on that point are not to be had, but observers who are used to studying the subject are sure that there is decidedly more coal in this section at present than there was last spring, and the belief is spreading that it will continue.

It has not been denied by anyone that Canada has had a big stock of bituminous all the season. The authorities seem to have had the same information, so that the reduction of allowance there comes from that fact more than from any special shortage here. Canada is not protesting against it, and the trade there is dull, perhaps quite as dull since the restriction was ordered as before. Had there been any fear of resultant shortage the demand would have sprung up.

Bituminous prices are steady. Jobbers like to sell at mine prices, on account of the complication of side charges and they do not always agree on the delivered prices, but the f. o. b. Buffalo, over net ton, is about as follows: Allegheny Valley thin vein, all sizes, $4.64; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; smithing and smokeless, $5.85; cannel, $5.60 to $6.10 (in box cars).

Anthracite—The local distribution has improved a little of late, though not enough to meet the demand. As soon as the lake trade closes there will be an extra 100,000 tons a week to distribute, and Buffalo will of course get some of that. Shipments by lake are fair, though they steadily fall behind last season. For the month of August they were 482,000 tons, against 614,350 tons in August last season and a total of 1,777,476 tons for the season to September, as against 2,313,870 tons to the same date last season.

Lake shipments for the week are above recent averages, being 57,100 tons to Duluth-Superior, 20,500 tons to Milwaukee, 10,300 tons to Manitowoc, 8600 tons to Chicago, 7400 tons to Waukegan, 3200 tons to Fort Williams and 3000 tons to Sault, Ont.; total, 110,100 tons. Lake freights are strong at $1 to the Sault, 60-65c. to Chicago, 55c. to Milwaukee and Waukegan, 50c. to Manitowoc, 48c. to Duluth and Fort Williams. Side ports now pay $1 for small cargoes to slow docks.

CLEVELAND

Bituminous coal continues to move to the lakes and the Northwest in record style, shipments for the first eight days of September totaling 1,101,069 tons. Retail and industrial consumers are being pinched accordingly. Operations in the No. 8 district of southern Ohio were at a virtual standstill registration day — Sept. 12 — despite the fact that the means of registering at the mine had been furnished by operators, in accordance with the Federal Fuel Administration's request.

Bituminous—Charges that miners in the No. 8 district of southern Ohio have come dangerously near to sedition through refusing point blank to register at the mines Sept. 12 are being freely made by operators, who went to considerable expense to procure the proper blanks and have clerks sworn in by the proper authorities. Operations were practically down at many mines, operators said, and production for this week has been seriously impaired. Labor supply continues poor, both in quality and quantity, and the saving grace of the situation is the good car supply, operators declare.

The Pittsburgh Vein Operators' Association of Ohio has just announced shipments for the week ended Aug. 31, which show a total of 8876 cars dispatched in the week by members of the association. This shows the lake trade getting 5184 cars in the week, while railroad fuel amounted to only 1568 cars and Ohio shipments 1678 cars. The closest kind of a check is being kept upon shipments to industrials. Retail dealers continue to bear the brunt of the shortage by reason of the centering of efforts on the movement to the Northwest. Authorities at Columbus, Ohio, fear that Ohio mines will not top the 36,000,000-ton mark set last year, though 40,000,000 tons is the state's quota for 1918.

Retail dealers have come out publicly for increased charges for deliveries, claiming labor now is coming at 40 to 42c. an hour against 30 to 32c. when the present schedule was arranged. Delivery prices now permissible are $2.03 a ton to homes, $2.15 to apartments, schools and hospitals and $1.50 to large consumers. Both dealers and operators hold that a mild winter will mean coal enough for all, but a severe winter, like last year, will tax the industry as it never has been before. Production meetings at mines are not bringing material results, it is said. A start is being made on an inspection of power plants in northeastern Ohio to check back data gathered recently by questionnaires.

Lake Trade—September will prove a record month in the lake trade if shipments in the latter part of the month maintain the pace set by the opening eight days, when the fleet loaded 1,101,069 tons of bituminous, exclusive of bunker fuel. Coal is coming forward liberally, owing to diversions from other branches of the trade, and vessel capacity also is proving ample. Everything considered, the lake trade is in fair shape despite the fact it is a trifle over 1,000,000 tons now behind schedule. Shipments of bituminous coal westward through the Soo canals in August amounted to 2,517,000 tons, compared with 2,121,603 tons in July. Shipments of anthracite westward at the Soo in August reached 299,555 tons, as against 233,764 tons in July. Carriers are being slowed up by fogs in the rivers and channels, but dispatch is good at both ends of the route.

DETROIT

Supply of coal available for domestic use shows little increase in either bituminous or anthracite. Lake trade grows in volume of bituminous shipments.

Bituminous — While regulations of the state fuel administration have largely increased the tonnage of bituminous which must be consumed by household buyers, the supply of stock suitable for domestic use is not increasing rapidly. Jobbers report a slightly larger proportion of prepared sizes among consignments reaching Detroit, but mine-run is yet more plentiful than domestic lump and dealers report it is not easy to get stock adapted for use in hot-air furnace heating apparatus, which is the only equipment of thousands of Detroit homes.

The supply of coal for steam plants maintains a fair volume, though its quality evokes criticism from owners of some of the industrial plants which, under a recent order of the Federal Fuel Administration are obliged to supply their requirements from mines in Indiana and Illinois. The coal coming from these districts is described as far less desirable than the product of the West Virginia mines which the steam plants, with a few exceptions, are obliged to relinquish for the use of domestic consumers.

Anthracite—Applications for anthracite, received by the state fuel administration from owners of base-burner heaters, with the orders booked by dealers from consumers of the same class, are said to approximate 40,000. For supplying these consumers with the maximum of three tons, each, authorized by the fuel administration, about 120,000 tons of anthracite will be required. The rate at which anthracite is now coming into the city would indicate that orders will not all be filled for three months. Meantime the fuel administration has ordered dealers to deliver no anthracite on orders that have not been approved by the fuel administration, the purpose being to conserve all anthracite for the use of the base-burner owners. Homes dependent on hot-air furnace plants under the latest regulation may share any anthracite that remains when the base-burners are supplied. The furnace owners, however, must first obtain delivery of an amount of bituminous equal to one-half their total winter fuel requirement, which few are able to do at present.

Lake Trade—Loading of bituminous coal for shipment over the lake routes is proceeding in better volume than at any previous time this year. The vessel tonnage available is in excess of the cargo supply.

COLUMBUS

Lake and domestic demand holding up well. A slight overproduction of screenings. Car shortage reducing output in certain sections.

The coal trade in Ohio has been running along steadily during the past week. Demand for domestic and lake tonnage is as strong as ever and especial efforts are being made to supply the Northwest. More attention is being given to the domestic trade and a larger tonnage is being shipped to retailers, especially in the western part of the state. On the whole the tone of the market is satisfactory.

Lake trade is being rushed as rapidly as possible and the lower lake ports are busy. The movement of vessels is generally good and litte time is lost in loading and unloading. The upper docks are being kept free from congestion as the movement to the interior is good. Some progress has been made during the past few weeks toward making up the shortage which developed earlier in the season.

Domestic trade is showing considerable activity in every locality, but more especially in the western part of Ohio. Retail stocks are being replenished and dealers are making a large number of deliveries. The larger proportion of domestic grades comes from Ohio mines, as Pocahontas is now out of the market and only a limited quantity of West Virginia splints is arriving. Reports from many parts of the state show that 50 per cent. and even more coal is now stored in bins and cellars by householders, and the situation is well in hand. Retail prices are firm at the levels fixed by the Fuel Administration.

Production has been fairly good in most fields, but car shortage is now appearing on many of the roads and this will cut into the weekly output. Registration day was also partly celebrated as a holiday by miners, with bad results. Labor shortage is becoming more acute in the eastern Ohio district. It is estimated that the output in the Hocking Valley and Pomeroy Bend has been about 75 per cent. during the week, and in other districts about 65 to 70 per cent.

The steam trade is rather quiet. Because of a recent ruling of the Federal Administration no screenings or mine-run can be shipped into Michigan, and that is throwing a larger tonnage into Ohio. But prices are not being cut under the oversupply.

CINCINNATI

Disturbance to movement has been caused by embargoes, but demand from all quarters continues insistent, with good production and fair car supply.

Reports of confusion at mines and of anxiety on the part of manufacturing consumers and of the trade generally in parts of the Northwest, notably Michigan, affected by recent embargoes, indicate that the interruption to the usual coal movement has been received badly; but the shipment of a relatively large volume of fuel by all roads serving West Virginia and Eastern Kentucky mines continues, with a demand in excess of receipts.

The car supply varies, some mines reporting adequate rolling stock, while others still complain of lack of cars to take care of their present output. On the whole, it may be said to be normal, the difficulty being, as for some time past, that the demand is greatly in excess of the supply, which is true of cars as of coal, in spite of record loadings during the season

While the retail trade in this immediate section is well cared for, and will probably not suffer at all during the coming winter, industrial consumers, especially in nonessential or deferred lines of work, are now facing the probability of a lack of fuel, announcements from Washington plainly forecasting rigid adherence to the priority classes recently announced. The absolute necessity of giving war industries and the population at large all necessary fuel, for operating, on the one hand, and for warmth, on the other, is generally conceded, and this makes it apparent that current supplies during the winter may be below maximum needs.

LOUISVILLE

General situation shows little change. Good demand for all grades, and some western Kentucky mines turning down car-lot business except for old customers, being unable to take care of all demands. Eastern Kentucky production held back by shortage of cars and labor.

Cool weather during the past few days, coupled with idiotic rumors to the effect that the Fuel Administration would not allow coal for domestic stocking after Oct. 1, has resulted in a decided improvement in the domestic demand during the past few days. Numerous consumers who had been holding back in an effort to secure eastern Kentucky coal are now taking western, and glad to get it. Western Kentucky mines report production below normal, while the demand is much greater due to the fact that no eastern Kentucky coal to speak of is reaching Louisville or the western and southern sections of the state. Western Kentucky coal is going into Jeffersonville and New Albany, across the river from Louisville, but not into any other sections of the state. At the present time all Kentucky coals are barred from Indiana, causing much complaint in that state.

Eastern Kentucky is being held back by the shortage of the car supply, which is now only about 50 to 60 per cent. of the required allotment. The labor situation is poor and is becoming worse, due to men going into other lines and back to the farms for fall harvesting. The wagon mines are getting a good supply of box

cars from northern roads, which are being returned from southern points under load. However, gondolas and open cars are scarce, and many of the tipple mines are having trouble.

Most of the eastern Kentucky grades of coal, especially gas and byproduct coal, are now moving to the Northwest and the lake district, and with the exception of some mine-run coal, little is being consumed in the state or moving south to the textile and cotton districts. At the present time jobbers could place practically the entire output of eastern Kentucky lump without difficulty, there being a big demand and practically no supply.

BIRMINGHAM

Production lags despite special efforts to stimulate the output. Labor shortage and irregularity coupled with car shortage hinder operations greatly. Trade conditions without change of any import.

The output of coal from the Alabama field is falling much below the tonnage rightfully expected from the producing facilities afforded. The official figures for the week ending Sept. 7 have not as yet been compiled, but the output will probably not show much if any improvement over the week of Aug. 31, when it dropped to 390,000 net tons, the lowest previous record since June averages.

The loss of output from the Mary Lee mine of the Alabama Co., which was recently flooded, the accident resulting in the death of four mine employees and considerable physical damage to the entrance of the slope and manway, will approximate 8000 to 10,000 tons per week, resumption of operations not yet having taken place.

The building of a siding from the Frisco main line at Dora, Ala., to the mines of the Dora Fuel Co. will enable that operation to increase its production considerably.

Local trade conditions have shown no change of importance in the past week. Although the steam situation is not as tense as it was several weeks ago, there is a demand for more tonnage than is available by a good deal, and the domestic market is strong. There was a slight falling off in the volume of domestic coal sold by retailers during August as compared with July. Some adjustments are being sought in classification of mines and prices as announced in the Fuel Administration order of Aug. 23.

Coke

CONNELLSVILLE

Dry zone resolution important. Coking coal production heavy.

In view of the repeated assertions of coke operators for months past that the chief barrier to heavier production of Connellsville coke has been "booze," the most important item in the coke trade for weeks is the passage by Congress of the resolution empowering the President to establish dry zones around munition plants and coal mines. While there is no knowledge that formal steps have been taken to place before the President information that this power should be invoked in the case of the Connellsville coke region, it goes without saying that this will be done. Such things are no longer considered radical, as the question has just been raised whether the whole of municipal Pittsburgh may not become dry through the establishment of Student Army Training Corps at the University of Pittsburgh and the Carnegie Institute of Technology, as a permanent camp means a ten-mile dry radius.

There is no material change in the production of either beehive or byproduct coke. Taking the two together, the Connellsville region is supplying more coking coal than ever before. Lately it has been making about 340,000 tons of coke a week, and has been shipping somewhat over 200,000 tons of coal, most of which goes into byproduct coke ovens. The region's best coke output was about 425,000 tons a week, in 1916, and at that time scarcely any coal was shipped. To balance the loss in coke output in the region about 125,000 tons of coal would have to be shipped elsewhere for coke making, and doubtless the proportion runs higher than that.

Through the activity of the Fuel Administration the Consolidated Coke Co. has refunded to two consumers about $80,000 on account of inferior quality of coke furnished, the difficulty about quality having arisen from the destruction of the company's washery. The award is much less than the loss experienced by the consumers.

The coke market is in about the same condition as formerly, there being practically no open offerings of furnace coke, which is allocated whenever it appears in surplus, but with fair offerings of foundry coke. The best prepared material from old dumps, over ¾-in., continues to bring $6.75. The market in general remains quotable at set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30, per net ton at ovens, Connellsville region.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Sept. 7 at 345,210 tons, an increase of 6960 tons, and raw coal shipments at 203,700 tons, a decrease of 8300 tons.

Middle Western

MILWAUKEE

All grades of anthracite, except buckwheat, advanced 25c. per ton. Coke manufacturers refusing new orders. Coal trains moving out freely.

Milwaukee coal dealers have received orders from the fuel administration to advance all grades of anthracite, with the exception of buckwheat, 30c. per ton, dating from Sept. 3. No reason for the advance was given, but it is surmised that it is to cover the customary increase of 10c. per ton for June, July and August, which was waived this year in order to stimulate summer purchasing. The anthracite scale is now as follows: Chestnut, $11.60; stove, $11.50; egg, $11.30; buckwheat, $9.75. An additional charge of 50c. per ton is made when coal is carried in to bins.

Coal is coming in freely by lake, and dock men are using their best efforts to transport the product to the interior before the grain crop movement usurps cars and track facilities. One day during the past week a coal-laden train of 52 cars left the city northward bound. Five locomotives were required to move the train.

Receipts by lake thus far in September foot up 19,000 tons of anthracite and 197,988 tons of bituminous coal, making the aggregate of cargo receipts since May 1, 383,977 tons of hard coal and 2,344,400 tons of soft. The soft coal record is a little ahead of the same period last year, but hard coal shows a slight falling off.

Coke manufacturers are refusing new orders for the present, ostensibly to catch up with the accumulation of orders; but it may be that they prefer to stock up rather than sell at the 30c. cut recently ordered by the fuel administration on all coke produced in byproduct ovens except in the states of Alabama and Washington. Coke has been retailing at $10.25 per ton, with an extra charge of 50c. per ton for carrying in.

ST. LOUIS

A continued quiet market with a surplus of all sizes of coal from the Standard field unbilled. Steam and domestic demand easing up. Equipment more plentiful and conditions show improvement.

The local market is in an easy way. The demand for everything is exceedingly light, other than Carterville grades. The country call, which was anticipated to be good in September, has not materialized to any great extent up to the present. Steam coal continues to lag on all sizes and were it not for the demand for the railroad tonnage the Standard market would be in a deplorable condition.

In the carterville district the mines have been idle unnecessarily two days. One was for the primary and one for the registration. This idleness was not general, but at many mines the miners could have worked instead of laying off. Car supply is somewhat better in this district this week and transportation has also shown improvement, but the tonnage has not increased. It developed this week that a large tonnage of this coal was going to southern and southwestern points for steam, where other coals could have been substituted and permitted this coal to go farther north where it is needed. The Fuel Administrations of Missouri and Arkansas up to the present time have not taken the firm hold of this situation that necessity almost demands. The railroad tonnage out of this field still continues good. Labor is still short, and the power supplied the mines by the Public Utilities Co. is still the cause of much loss in idle time. Working conditions in the Duquoin field are somewhat similar to that in the Carterville.

The tonnage in the Mt. Olive field now exceeds the demand, and there is a heavy surplus unbilled daily on account of no available market. Up to the present this market has been taking care of all the business offered and the new condition was one that was not anticipated.

There is much agitation among the operators in the Illinois field that the zones in Missouri be raised. Some producers in Illinois have been able to secure a permit somewhere that enables them to ship Illinois coal in stock cars out into Nebraska, and there is some feeling between the operators over this discrimination.

Cars are not very plentiful, but even at that, they are furnished in greater numbers than the market can readily take care of. Considerable of this coal is moving to Chicago and into Michigan points, but not in a volume sufficiently great to keep the mines working full time. The prospects are not exceedingly bright for either the Standard or Mt. Olive coal for some time to come, unless severe weather sets in.

Steam sizes are exceedingly heavy and hard to move even when prices are cut. In St. Louis proper business is almost at a standstill. There are no eastern coals coming in and a very slight tonnage of Arkansas. The St. Louis Fuel Committee was sustained the past week by the Fuel Administration at Washington on the price it made on gas house coke of $11.25 to the consumer delivered. The previous price was $13.00.

The prevailing market price per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.70	2.55@2.70	2.35@2.55
No. 2 nut	2.55@2.70	2.55@2.70	.....

No. 5	2.05@2.20	2.05@2.20	.....

Williamson and Franklyn County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

SEATTLE

Northwestern states consuming more coal than they produce by over three and one half million tons. Shortage to be felt this winter is prediction of operators.

That the four northwestern states of Washington, Oregon, Idaho and Montana are not producing coal to the extent that they are consuming it has just been brought to light by figures made public by the fuel administrations of the four states. Washington will produce this year in the neighborhood of 4,600,000 tons of coal (although this estimate, which was made earlier in the year, may be somewhat high now) but the estimated consumption is conservatively placed at 5,411,402 tons, a difference of over 800,000 tons. The difference may be increased materially if more labor is not forthcoming. As it is, the state has lost over 1000 coal miners since the first of the year, which means a daily loss of 1800 tons of coal mined, which if not remedied by the first of the year will mean over 1,000,000 tons difference between the production and consumption of coal in this state. Idaho is not producing any coal this year, and the consumption is estimated to be 725,000 tons. Montana will produce 4,400,000 tons and consume 5,500,000, while Oregon will produce 39,000 tons of coal and consume 786,446 tons. Both production and consumption figures show large increases over 1917, as may be seen from the following figures:

	1917		1918	
	Production	Consumption	Production	Consumption
Washington	4,002,749	4,161,402	4,600,000	5,411,402
Oregon	43,000	686,446	39,000	786,446
Idaho	.....	725,000	.....	895,000
Montana	4,400,000	5,378,202	4,400,000	5,500,000
Totals	8,445,749	10,951,050	9,039,000	12,592,848

These figures would indicate a shortage in coal in the Northwest this winter as coal operators have pointed out since the first of the year or since the Federal Fuel Administration ruled that the western states would have to supply themselves from their own mines this year.

COAL AGE

Volume 14 New York, September 26, 1918 Number 13

Partners with the Kaiser

By Frank H. Kneeland

THE United States is engaged in a titanic struggle—a world conflagration—largely because a greedy national autocracy saw fit to break or disregard its plighted oath, to consider treaties made in all sacredness as mere "scraps of paper." The issues at stake are clear, the social and moral obligations distinct. Can we logically expect Uncle Sam, who is battling with all his might for principles of honor on foreign soil, to countenance, much less condone, breaches of faith at home?

President Wilson's reply to the striking machinists of Bridgeport, the taking over of the Smith & Wesson plant by the Government, and Dr. Garfield's recent message to the striking miners of the anthracite region make the Nation's position toward faithless firms or individuals unmistakable. While the country faces national autocratic greed abroad it cannot and will not be hamstrung by individual or class greed at home.

Guns, shells and coal are all war necessities. In this time of national peril, when the very principles of democracy and justice are at stake, whosoever willfully deserts his desk, his lathe or his pick cannot be classed as a mere drone or a slacker—he is a public malefactor. Such desertion cannot now be regarded in the same light as it might be in ordinary peace times. It is now little, if any, short of rank, vile, contemptible treason.

Nor can public opinion be expected to support the action of either anthracite miners or Bridgeport machinists. The payers of war taxes, the purchasers of Liberty Bonds, the buyers of thrift stamps, the conscientious obeyers of the food administration's and other Governmental edicts involving more or less sacrifice, all have a direct and vital interest in keeping the flow of war munitions continuous and unbroken.

Successful prosecution of the war means the practice of team work. Thus far in the conflict American labor as a whole has shown a decided will to do and a marked eagerness to coöperate with the Government of the United States against the common enemy of decency and humanity. The few instances of willful departure from this course are therefore all the more prominent and glaring. And no labor faction can justly claim that thus far the Government has ever been niggardly in fixing or helping to fix labor's compensation.

However, the higher standard by which a striking worker may be judged is a moral standard—a blood test. An idle lathe in a munition factory or an idle working place in a coal mine may in all possibility mean blood needlessly spilled on the already corpse-strewn fields of France. No right thinking person with kith or kin in his country's service can condone, much less sanction or approve, such infamous desertion.

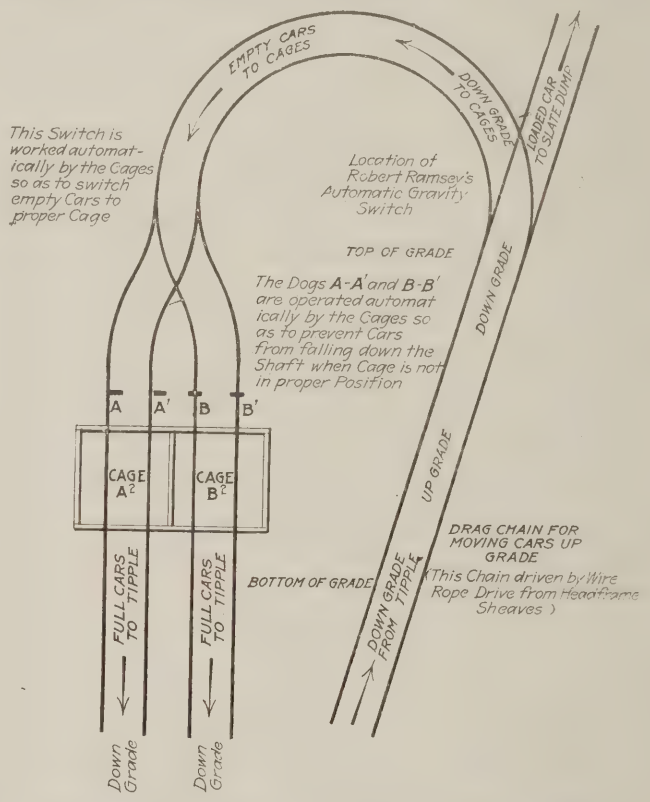
IDEAS AND SUGGESTIONS

How to Blacken Bolt Heads

Specially prepared lacquers can be obtained from supply houses for giving metal work for electrical switchboards and other purposes a dull black finish. If such preparations are not available, dull black paints, which will serve in emergencies, can be obtained in 10c or larger cans at most hardware stores or paint shops. The following process has been used successfully for giving bright-finish, steel cap-bolt heads a dull black finish. First, heat the bolt to a dull red in a blowtorch flame, then dip it in asphaltum paint. Next burn the paint off with a blowtorch and rub the bolt head with a cloth while it is still warm. If the bolt is permitted to cool before it is rubbed with the cloth, the resulting finish will be glossy instead of dull.

Ramsay Automatic Switch

BY ERSKINE RAMSAY
Birmingham, Ala.



"The Automatic Tipple Switch," which appeared in the Aug. 8, 1918, issue of *Coal Age*, reminded me of the automatic switch which my father designed and installed along about 1880, at the Westmoreland shaft of the Westmoreland Coal Co., at the time he was connected with that concern. Before installing this switch, it was necessary to throw the switch by hand when a car of slate or rock came up, in order to prevent it from running around by gravity to the hoisting shaft.

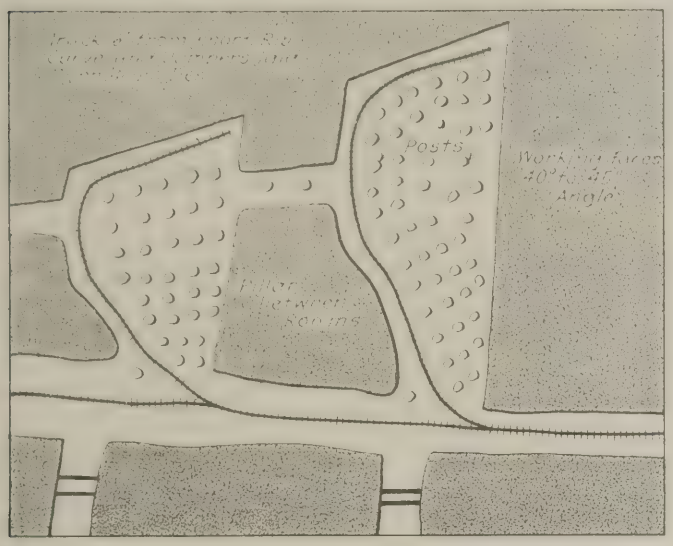
SWITCH AUTOMATICALLY DEFLECTS LOADED CARS

On one occasion the switch was negligently not thrown, resulting in the loaded car of rock running around rapidly to the shaft, where it broke through the wooden gate and fell to the bottom, striking the cage on which a number of men were standing at the time, ready to be hoisted out. Fortunately, the overhead cover of the cage was strong enough to deflect the car into the bottom landing, and as a result nobody was seriously hurt.

This accident suggested to my father the advisability of getting up a switch that would automatically deflect the loaded cars to the slate dump, and as a result he designed the device shown in the accompanying illustrations. The then local superintendent of the Westmoreland shaft, a large man, contended that the additional weight of a loaded car would not throw the switch, and

DETAILS OF AUTOMATIC SWITCH INSTALLATION

after some discussion my father made a wager that the switch would be sensitive enough to operate with only the superintendent in an empty car. And on a first trial it worked perfectly. The sketch was made by W. P. Little, a young engineer student then on his vacation from school, and who visited the plant shortly after the switch was put in.



Oblique Faced Rooms

BY G. W. SUTHERLAND
Blakeley, W. Va.

A system of haulage and an arrangement of working face and room tracks that has proved its usefulness is shown in the accompanying illustration. The rooms are driven on 50- to 60-ft. centers, according to the conditions of top and bottom. These rooms are turned at right angles off both entries of a pair. When they are widened out the working faces are cut so as to form a 40 to 45-deg. angle with the ribs. This gives a longer working face without reducing the pillar between rooms. Suppose the rooms are 30 ft. wide from rib to rib, thus

affording a 30-ft. square face. The 40- to 45-deg. angle will increase the working face from 30 ft. to 40 or 45 ft., according to the angle.

This, of course, makes a short and a long rib. The track is laid 6 ft. from the short rib; that is to say, the center of the track is 6 ft. from it. This track is laid straight to within 15 or 20 ft. of the working face so as to allow a good curve and is then extended across the working face. As the face advances the track of course advances with it. To do this the curve is dis-

ARRANGEMENT OF WORKING FACE AND ROOM TRACKS

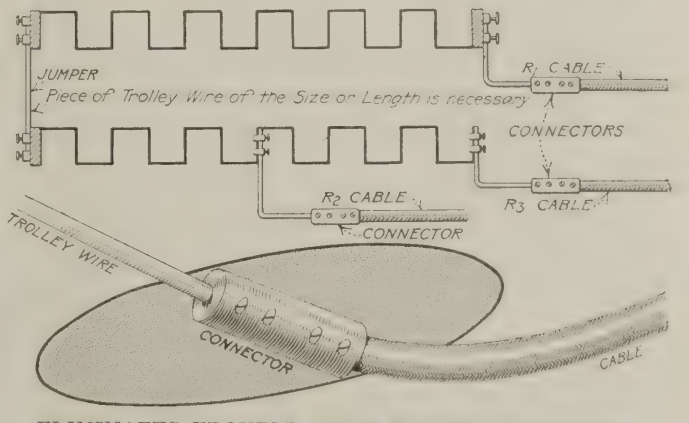
connected on the outby end from the straight track and thrown ahead with a bar, and short rails or jumpers laid behind the curve.

Where the mining machine undercuts 6 ft. there should be a pair of rails 6 ft. long and two pairs 12 ft. long. Thus when the track has advanced the length of these three pairs of short rails a pair of 30-ft. rails can be laid in their stead. The short rails and curve should be laid on steel ties and the joints fish-plated. Wood ties can be used under the long rails.

Where the roof is weak, timbers may be set up to the inside of the curve. If any impurities occur with the coal these are thrown back between the track and the long rib. Thus the short rib is always clean, and when the room is finished and the pillar ready to be drawn back the track is in place therefor, excepting the curve, which can be turned end for end, in other words, reversed, and in a short time relaid to the end of pillar. This track across the working face can be used to drive break-throughs without extra labor and expense when each room is finished.

If a shortwall mining machine is used to undercut the coal it can be unloaded and loaded from the straight track by disconnecting the curve and throwing it out of the way with a bar. Certain types of shortwall mining machines are provided with a reversible truck and can be loaded and unloaded at any angle.

This arrangement of working faces and room tracks gives the following advantages: (1) A longer working face is secured without reducing the pillars. (2) The same mining machine can undercut more coal with less unloading and loading, and with less moving. (3) Where there is an ample number of mine cars, each loader can have from two to four cars at the working face without being compelled to wait for the gathering locomotive, he can have work for two or three hours according to the size of the cars. If the cars hold two tons, four cars will give the loader eight tons. Two trips per day will allow him to load 16 tons, which is a big average per man. (4) One gathering locomotive can serve from 30 to 40 places with this arrangement and give the loaders all they can do.



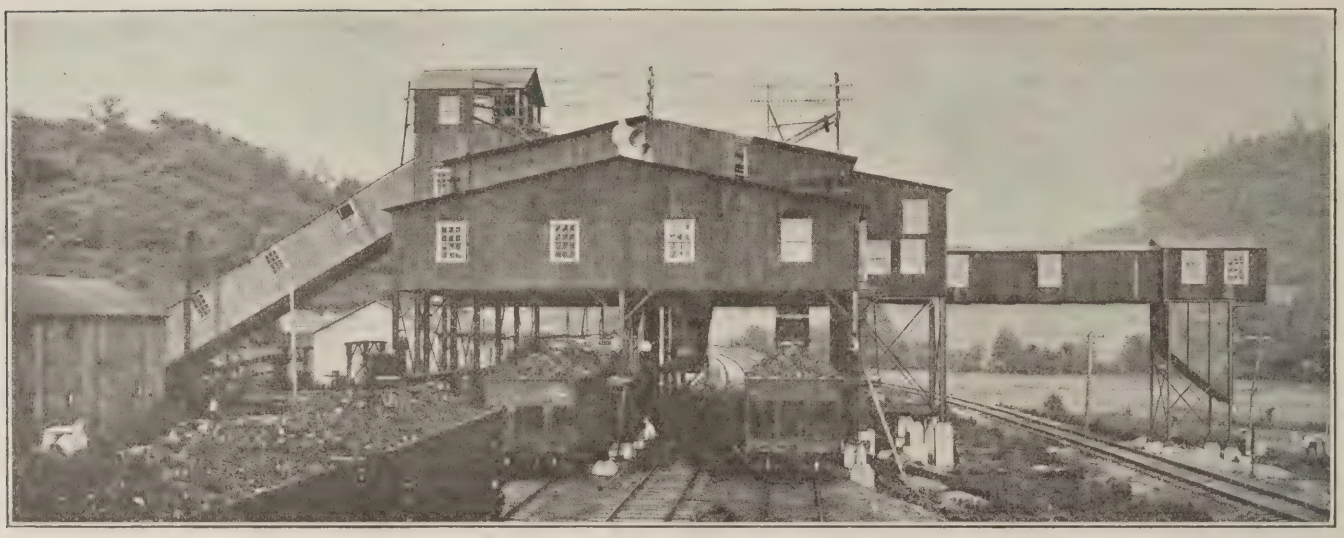
In my experience, when men have to wait an hour or so for their turn they get disheartened and go home. This arrangement keeps them busy. A storage-battery locomotive is the best to use with this layout, but a cable-reel locomotive can be employed with fair success if a double cable is used. By this means rail bonding will not be necessary in rooms.

Resistance Terminal Connections

By F. W. Sakon
Johnstown, Penn.

On mining locomotives the lead wires that go to the resistance terminals are usually soldered at the ends. After a few weeks' or months' use the solder runs out or melts, thereby leaving the strands of wire loose in the terminal. These then start to burn in the terminal, and when they are to be disconnected the wire must be cut off and the terminal drilled out or the resistance taken apart and the terminal changed.

I have successfully overcome this difficulty by taking a piece of copper trolley wire about 8 in. long, of either 2/0 or 4/0 size according to the diameter of the hole in the terminal, placing this in the terminal and bending it to suit conditions, and then taking a tube connector and joining the resistance lead to the trolley wire therewith and tightening the set screws and tap-



ELIMINATES TROUBLE FROM BURNED TERMINALS

ing them so that the screws cannot work loose. This makes a tight electrical connection and eliminates the trouble arising from burned terminals in the resistance.

I also use trolley wire in making jumpers from one resistance unit to another. I find that these give less trouble than soldering little tubes to short pieces of cable. When it is necessary to loosen the connection for testing purposes, they are more easily inserted again, with less difficulty than the leads which are soldered.

A miner refused to take the advice of a first-aid man and have a scalp wound dressed. As a result infection set in, and he lost several weeks' time. There are more ways than one of being a slacker.

Valley Camp Coal Co.'s Tipple at Parnassus, Penn.

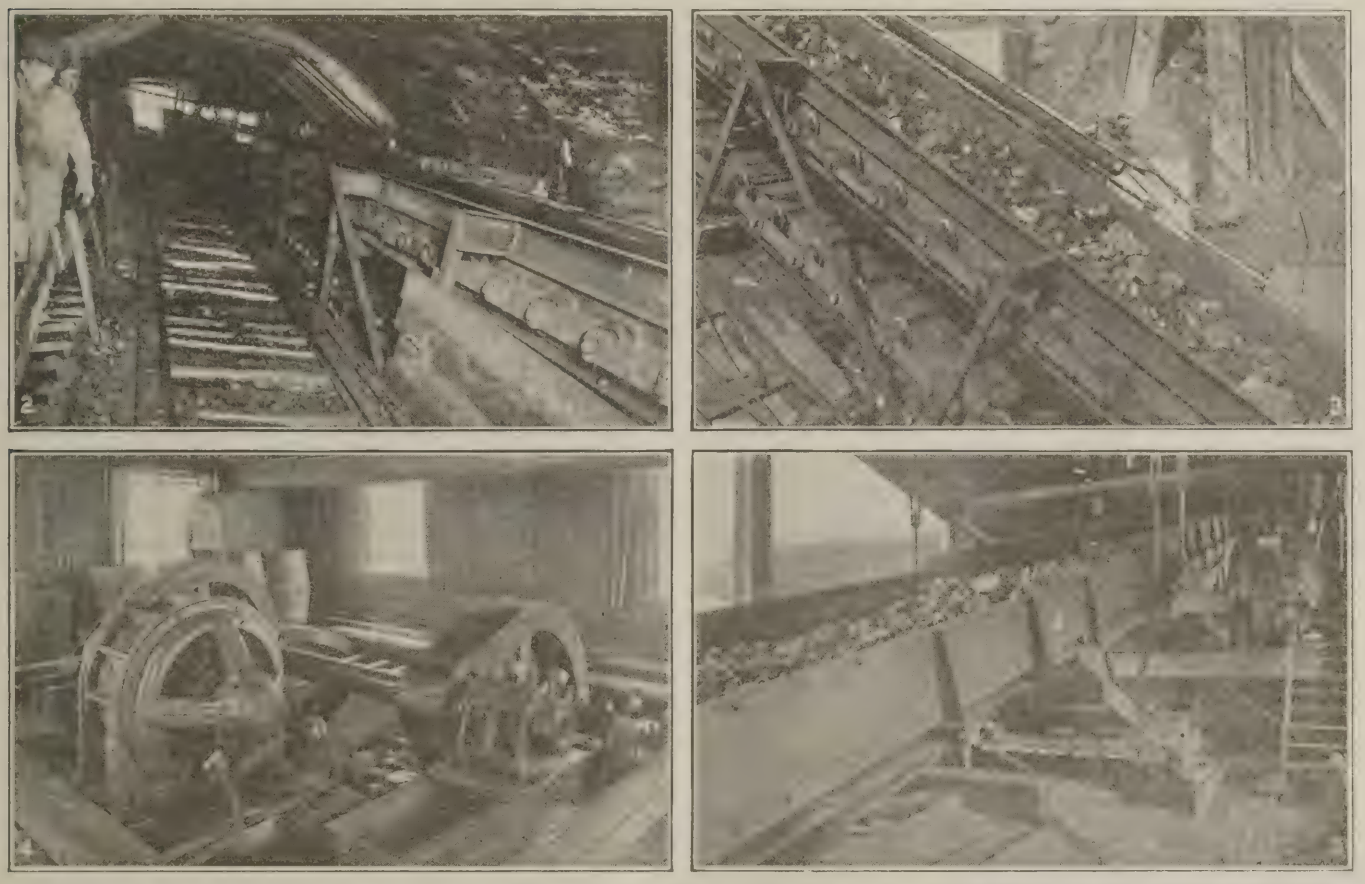
By GEORGE S. JAXON
Philadelphia, Penn.

SYNOPSIS — *This tipple is designed to make four sizes of coal, the two larger of which are hand-picked. Bone is crushed and used as boiler fuel. A unique feature of the plant is a conveyor designed to facilitate cleaning the tracks under the tipple of spillage from the cars after the day's run.*

ON THE banks of the Allegheny River in Westmoreland County, Penn., approximately 18 miles northeast of the City of Pittsburgh and situated on the Buffalo & Allegheny division of the Pennsylvania R.R., lies the town of Parnassus. On the outskirts of the village is located one of the most modern and up-to-date steel tipples in the bituminous coal fields of the state, the property being known as the Kinloch Mines. The Valley Camp Coal Co. commenced mining operations here in the year 1917, working the upper and lower Freeport seams. The lease contains about 2500 acres of coal, which averages 84 in. in thickness. The president of the company is James A. Paisley, of Cleveland, and the general manager and superintendent H. E. Kinloch, of Parnassus. The development of the mine is carried on by the wall-and-pillar system through a slope driven on a 30-deg. inclination. Electrical power is utilized for both the inside and the outside operation, and a working force of approximately 330 men is employed. The output for the last fiscal year was 505,274 tons of run-of-mine coal. The coal is brought in wooden mine cars from the working face to the foot of the incline inside the mine, where it is transferred to power-driven machinery for removal to the tipple structure for the necessary sizing and loading.

FIG. 1. OUTSIDE VIEW OF TIPPLE EQUIPMENT

The coal company, being desirous of preparing its output for market in the best and most economical manner, sent out requests for competitive bids covering an equipment capable of handling an hourly output of 450 tons of bituminous coal based upon the following percentages of different sizes: Lump, 25 per cent.; egg, 18 per cent.; nut, 17 per cent.; slack, 40 per cent. The following is a detailed description of the equipment finally accepted by the company as being the one most suitable for the requirements. The leading illustration shows a general outside view of this equipment. The mine cars, which are of 2½ tons capacity with a gage of 44 in., are delivered to a Phillips automatic cross-over dump by which they are emptied into a steel hopper of five to six tons capacity. Under this hopper is located a steel apron



feeder conveyor 42 in. wide, which feeds the coal at a uniform speed over a slack bar screen onto the steel pans of an inclined apron conveyor. The feeder is constructed of ¼-in. steel pans mounted upon a double strand of 9-in. pitch steel-strap roller chain, which travels upon a 30-lb. T-rail track. The coal being screened before its delivery to this unit insures a cushioning effect that tends to preserve intact the large-sized coal. This passes over the screen and onto the conveyor, which already carries the small material.

The conveyor is slow moving, having a speed of 75 ft. per minute and an entire length of 428 ft. from the center of foot sprockets to the center of head sprockets. Of this length 403 ft. is on an inclination of 30 deg., while the remainder at the foot end is horizontal. This unit is employed for delivering the coal from the dump hopper to the shaking screens. The conveyor pans are constructed of $\frac{3}{16}$-in. steel plates of the double-beaded, corrugated, overlapping type, with a bead in the center to act as a stiffener. At the same time this prevents the coal from sliding back when traveling up the incline. The apron pans are attached to a double strand of special 18-in. pitch, forged-steel strap roller chain, the side bars of which are made of ½ x 5-in. steel flats with ends swelled to 1 in. in thickness. The joints are constructed with 2¼-in. diameter case-hardened steel pins, having milled ends fitting in the outer side bars, while steel bushings are introduced locked in the inner side bars. These bushings carry 8-in. diameter, flint-rim tread, single-flanged, inclosed oiling rollers, which in turn travel on a double track of 30-lb. T-rails, which form part of the structural steel supporting framework. Traveling steel side plates are used to insure a perfectly clean unit, while a continuous stationary side plate of No. 10 steel is placed above the entire length of the conveyor pans for the purpose of easily carrying the capacity of 450 tons per hour.

At the head of this conveyor a substantial steel discharge chute delivers the coal either to the shaking screens or by means of a mechanically operated fly-gate diverts the run-of-mine through the slack hopper to railroad cars upon the nut track. This is employed in case of emergency, when for some reason parts of the tipple machinery may be out of commission.

The foot shaft is equipped with a chain sprocket for operating the apron feeder through a strand of combination drive chain. Fig. 2 shows a view of the conveyor traveling up the inclined slope. Fig. 3 shows the same conveyor with the coal on the upper strand. In Fig. 4 is shown the 150-hp. electric motor with back gearing, which actuates this unit.

The coal is delivered from the conveyor onto the shaking screens, which are moved back and forth at the rate of 100 shakes per minute. The screens are of the hanger type, 7 ft. 6 in. wide, with sides approximately 12 in. deep. They are constructed of steel throughout and stiffened by means of structural shapes. Great care was exercised in designing these screens to prevent excessive drops to the coal, thereby eliminating breakage as far as possible. Fig. 5 shows the coal passing over the shakers with steel veil plates in their

FIGS. 2 TO 5. VIEWS OF CONVEYOR FOR DELIVERING COAL FROM DUMP HOPPER TO SHAKING SCREENS
Fig. 2—A view of the conveyor traveling up the inclined slope. Fig. 3—Same conveyor shown in Fig. 2, with coal on the upper strand. Fig. 4—The 150-hp. electric motor which actuates the conveyor. Fig. 5—Coal passing over the shakers

FIG. 6. LUMP TABLE AND PICKERS AT WORK

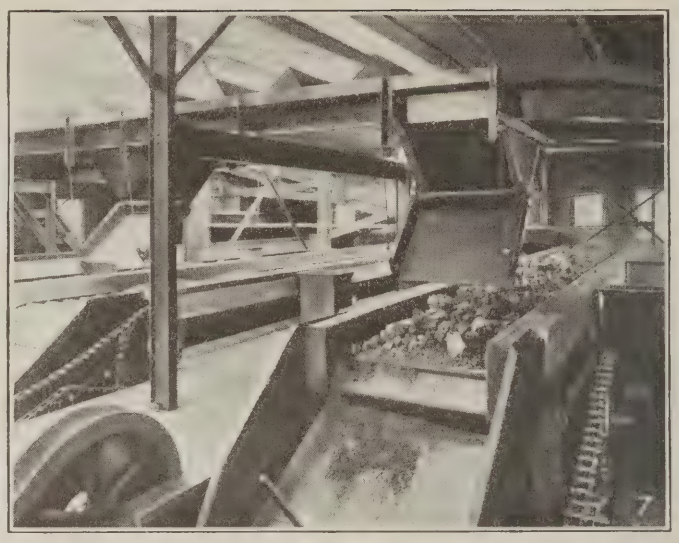


FIG. 7. INTERIOR VIEW OF PICKING HOUSE

bottoms for the purpose of loading run-of-mine coal onto the lump-coal picking table. The shaking screens are operated by means of an eccentric shaft of sufficient size and strength to oscillate them at the speed mentioned above. Eccentrics of the ball-and-socket type are utilized to insure perfect alignment.

Considerable care has been exercised also in the design of the picking house, so as to secure ample lighting and ventilation. This insures the proper cleaning of coal before its delivery to the railroad cars. Fig. 6 shows a view of the lump table and the pickers at work. Fig. 7 is a view of the interior of the picking house, showing the lump, egg and nut tables. The amount of light secured from the skylight visible in this illustration may be readily perceived.

The picking tables discharge their contents over perforated plates in discharge chutes. These take out the final breakage that has been made by the pickers on the tables, before delivery is made to the loading booms.

The tables are constructed of $\frac{3}{16}$-in. steel corrugated pans, mounted on a double strand of steel-strap chain whose joints are $\frac{3}{4}$-in. steel pins, carrying steel bushings encircled with $3\frac{1}{2}$-in. single-flanged rollers traveling on 20-lb. T-rails, carried on structural-steel frames throughout their entire length.

The coal is delivered from the picking tables over the discharge chutes to the loading booms. These convey it to the railroad cars. Fig. 8 shows a typical view of the lower floor with the booms passing through openings therein to the cars. The booms are of the same general construction as the picking tables and are of ample capacity. Fig. 9 shows a general view of the machinery for driving the picking tables and loading booms, with all gears and chain drives properly protected by steel guards.

The refuse and bone picked from the tables is delivered to the bone conveyor by chutes, the bone to the upper strand and the refuse to the lower strand. The refuse travels on the lower strand to the steel bin shown on the right in the leading illustration. This bin is constructed of $\frac{1}{4}$-in. plate and is equipped with draw-off valves at the lower end of the hoppered bottom to facilitate loading into railroad cars on the outside track. The bone is conveyed along the upper strand to the bone coal crusher, which reduces this product to slack size for fuel purposes. The conveyor in question is composed of suspended $\frac{5}{16}$-in. steel flights, attached to a double strand of 12-in. pitch steel-strap roller chain at 36-in. intervals. The steel flights measure 8 in. deep and 20 in. long. This unit measures 112 ft. center to center and is mounted inside of a structural-steel frame throughout its entire length.

FIG. 8. TYPICAL VIEW OF LOWER FLOOR

FIG. 9. GENERAL VIEW OF DRIVING MACHINERY

The slack coal is delivered from the shaking screens by means of a hopper and chute direct to the slack conveyor. This conveyor is made up of ¼-in. steel-plate flights measuring 10 in. deep and 36 in. long, rigidly attached to a double strand of 12-in. pitch steel-strap roller chain at intervals of 36 in. The chain is made up of 2½ x ¾-in. steel flats and the joints constructed with ¾-in. diameter steel pins provided with case-hardened steel bushings carrying 3½-in. solid straight-face cast-iron rollers. On both the carrying and return runs the chain rollers travel on steel angle trackage, which forms part of the structural-steel frame in which the conveyor is mounted. Provision is made at the discharge end for delivering to railroad cars. This conveyor is shown in Fig. 10.

The mixing conveyor is employed for delivering lump, egg and nut coal to the crusher or for mixing the foregoing sizes with slack for delivery to any of the tracks. It is located at the discharge end of the picking tables, where the lower strand passing beneath the tables collects the different sizes of coal by means of a fly gate in the table discharge chutes. The coal is then carried along this strand and up the vertical strand to the upper runway, where by means of valve openings it can be delivered to the crusher or to the different tracks. This unit is composed of gravity discharge buckets measuring 24 in. wide by 54 in. long and 11 in. deep, rigidly attached to a double strand of 18-in. pitch steel-strap roller chain at intervals of 36 in. The side bars of the chain are made of ½ x 2½-in. steel flats with joints constructed of 1¼-in. steel pins. These are provided with case-hardened steel bushings carrying 5-in. straight-face, flint-rim tread, inclosed oiling rollers fitted with Bennett self-closing oilers.

The entire machine runs on steel tracks supported by structural steel framework, which in turn is securely attached to the driving terminal and corner shaft supports. The buckets are guided on the vertical runs by means of steel angles. This machine is driven through gears from an electric motor. Fig. 11 shows the lower strand of this conveyor, while in Fig. 8 the discharge chutes from the top strand for mixing purposes is clearly shown. In connection with this conveyor a clean-up elevator is employed for the purpose of ridding the tracks beneath the tipple of the spillage which accumulates at the end of a day's run.

At the time the accompanying photographs of this equipment were taken the erection was not quite completed. However, Fig. 1 shows a second typical outside view of the equipment. The long inclined conveyor carrying coal into the tipple may be here plainly seen.

The electrical equipment for operating all the apparatus here described may be enumerated as follows: One 150-hp. motor for driving the inclined conveyor and apron feeder; one 35-hp. motor for driving the shaker screens; one 30-hp. motor for the picking tables, booms, boom hoists and slack conveyor; one 40-hp. motor for driving the mixing conveyor and the clean-up elevator; one 7½-hp. motor for the refuse and bone conveyor; one 150-hp. motor for the large run-of-mine crusher; one 35-hp. motor for the small bone-coal crusher. These are of the General Electric Co.'s make and are complete with automatic starting panels arranged for push-button control.

The tipple building is of steel construction, covered on sides and roof with "Duck Brand" corrugated asbestos-protected metal. The picking house section is equipped with "Lupton" steel frame skylights and "Larson" suction ventilators. The entire equipment was designed, fabricated and erected complete by the Link-Belt Co., of Philadelphia, Chicago and Indianapolis.

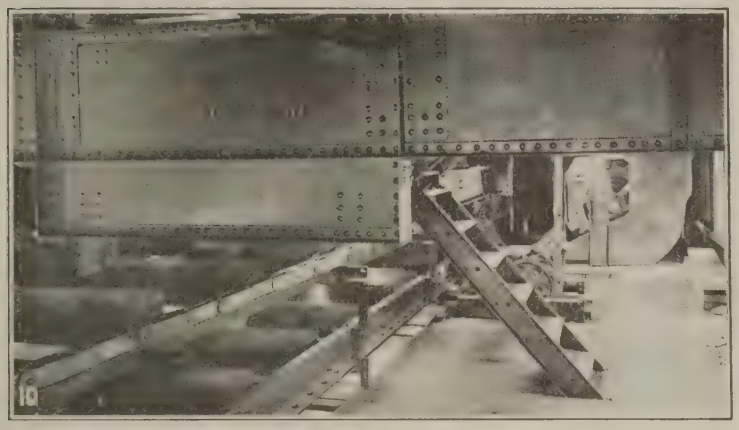

FIG. 10. THE SLACK CONVEYOR

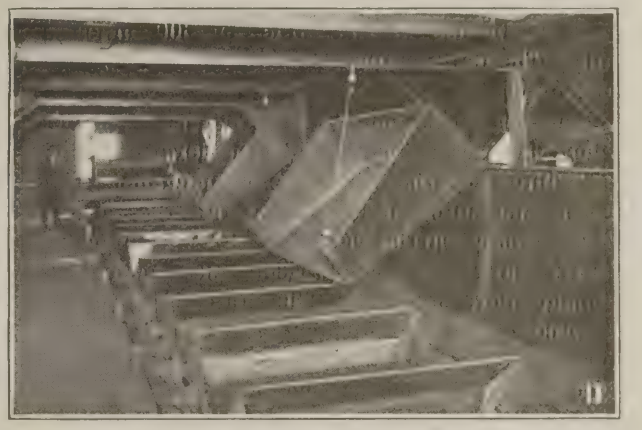

FIG. 11. LOWER STRAND OF CONVEYOR

Excess Air and Heat Efficiency

For a given furnace and a given fuel there is a certain percentage of excess air which gives the maximum over-all efficiency of a steam-generating apparatus. If the supply of air is increased beyond this percentage the over-all efficiency drops because of the heat lost in heating this extra air. If, on the other hand, the air supply is decreased below this best percentage, the heat losses increase on account of less complete combustion. These are the two principal causes of heat not being available for a boiler and the ones that are at all times affected by the air supply.

The percentage of excess air giving the lowest sum of these two combined losses varies with the size of the combustion space and the kind of coal. When the combustion space is large smaller air excess is necessary to obtain good combustion than when the combustion space is small. With coals having low percentages of volatile matter less excess air is needed for nearly complete combustion than with coals having high percentages of volatile matter.

Shipping Facilities at the World's Largest Coal Mine

By R. W. MAYER
Connellsville, Penn.

SYNOPSIS—*A mine that produces 7000 tons of coal per day requires somewhat elaborate tipple arrangements, especially as this tonnage may be shipped either by rail or river. In order to handle the output mine cars must be dumped at the average rate of one every 12 sec. throughout the entire day. Sometimes this speed is exceeded.*

AN ACRE of coal a day is removed from underground in the Vesta No. 4 mine. When working to capacity and full handed, this operation employs about 2200 men. Nearly 300 miles of steel track is in use in the mine, or 600 miles of steel rails. The daily output is in the neighborhood of 7000 tons of coal.

Last year this one mine produced 1,795,000 tons. When the fact is taken into consideration that during the winter months when the Monongahela River was frozen and shipments went by rail the mines had to work at only partial capacity, this output can be considered large. A comparison may make the large tonnage more striking. The State of Washington has 63 producing mines, which last year mined 3,623,196 tons of coal. The output of Vesta No. 4 mine was almost half as much as that of the entire state, which is the largest coal producer in the Northwest.

Vesta No. 4 mine is probably the largest coal mine in the world, and to any one interested in mining the methods employed here as well as the mine itself are fascinating. It is situated near California, Penn. California is a clean, beautiful, little city, the home of retired capitalists and the State Normal School. It is situated 50 miles south of Pittsburgh, on the Fourth Pool of the Monongahela River. The Pennsylvania R.R. runs through it, while the Pittsburgh & Lake Erie R.R. follows the opposite bank of the river.

The mine is operated by the Vesta Coal Co., J. B. Laughlin, president, and B. F. Jones, general manager. This company is a subsidiary of the Jones & Laughlin Steel Co., which consumes all the coal the Vesta Coal Co. produces and has to buy more. Ninety-two per cent. of the steel manufactured by this company is now sold to the United States Government.

The Vesta No. 5 mine produced 1,340,000 tons of coal last year. Vesta No. 6 has a daily output of about 2500 tons. It is not unusual for this mine to produce 12 tons per day for every man working at the face. Vesta No. 7 mine, which is just being opened on a large scale, will begin shipping coal about Nov. 1 of this year. It is on the left bank of the Monongahela River, opposite Silicia. The Crescent mine of the Pittsburgh Coal Co. adjoins these mines; last year its output was 1,115,000 tons of coal.

All of these operations are in Washington County, Pennsylvania. In this county 118 companies operated 161 mines last year. It is estimated that there are approximately 3½ billion tons of coal in Washington County yet to be mined, or about 448,000 acres of the Pittsburgh bed. The market value of this unmined coal is about nine billion dollars.

The Vesta Coal Co., the largest shipper of coal by water, owns and operates seven steamboats and over 100 steel and wooden barges. It recently let a contract for 50 more all-steel boats to be used for carrying coal on the Monongahela River. It is expected to turn them out at the rate of about seven a month. They are now being built at the South 34th St. plant of the Jones & Laughlin boat-building department. The all-steel steamer "Elsey," now being built at Neville Island by the Davis Engineering Co. for the Vesta Coal Co., should be in the water by Oct. 1. It is named in honor of the company's transportation manager.

Will Soon Construct New Marine Ways

At the present the company has not sufficient facilities for repairing its boats. It will soon commence the construction of new marine ways to be over 200 ft. long. These will be built below the Wilton tipple, above Lock 3, on the left bank of the Monongahela River. The barges at present in use are from 100 to 200 ft. long. A 200-ft. barge holds about 1000 tons of coal. It is brought under the tipple for loading, is loaded, and replaced by another empty barge in 50 min. Barges 150 ft. long hold about 775 tons. The 100-ft. barges hold 450 tons and are loaded in 18 min. It requires from 24 to 36 hr. for the steamer to tow loaded barges from No. 4 mine to the company's works at Pittsburgh and return with empty barges. A steamer usually tows four large barges and one small one.

Landing boats on the river at the tipple, with boilers and engines, are provided also with steam pumps which pump the water out of the barges. One end of the barge sinks when loading is commenced, causing the water to flow to that end. It is then easily pumped out. The steel barges are only pumped out once each trip, pumping being done at the tipple. The wooden barges have to be pumped out oftener. The steel barges are lined with wooden planks to save wear on their hulls.

The coal is loaded into the barges at the tipple in three layers to equalize the stress on the hull and prevent it from becoming "hogged," or broken. The barge is accordingly moved back and forth under the coal chute. All the coal from the tipple is loaded from one chute. A long steel boom with a sheave on its end, over which a steel cable runs, extends out on each side of the tipple over the top of the barge.

The cable which runs over the sheave on the lower boom is fastened to the upstream end of the barge. The cable running over the upper boom is fastened to the

downstream end of the barge. These cables are wound upon the drum of a steam donkey or hoisting engine, which is placed in the tipple directly over the river. The donkey engine pulling on these cables quickly moves the barge back and forth under the tipple coal chute.

A man stationed on the barge signals the donkey engineer how to move the barge by pulling a whistle cord. While the barge under the tipple is being loaded another empty one is placed upstream from and end to end with it, and the ends of the two barges are fastened together. When one is loaded it is pulled out from under the tipple by the cable on the donkey engine, and the empty barge, fastened to the end of the loaded barge, is pulled under the tipple chute by the same action, the loading being continued without interruption. The donkey engine cables for moving the barge under the coal chute of the tipple are quickly changed from the loaded barge to the empty one while one of its ends is receiving coal.

How the Work is Divided

One crew of men has charge of the loaded barges and another sees that the empty barges are placed in position as needed. A man stationed on the loading barge picks out what rock he can find. As the coal is fairly clean the amount of rock thus removed is small. An analysis of the coal shows about 3 per cent. of ash. About a foot of slate or cap rock overlays the coal and must be taken down. If this is carelessly allowed to become mixed with the coal, ash content may go to 15 per cent., but in practice seldom exceeds 9 per cent. As this drawslate is white in color it makes a contrast with the coal and is easily seen.

About 400 ft. above the tipple is an ice-breaking pier to which the barges are moored. This is built of heavy cribbing drift-bolted together and filled with rock. The tipple is an all-steel structure extending out over the river. Its outer end rests on a heavy cut-stone pier set at the edge of deep water on the river bank. Heavy concrete bulkheads extend from the pier back to the top of the river bank. Bulkheads, built of logs drift-bolted together and filled in behind with rocks, extend for several hundred feet up and down the stream from the tipple along the river bank. These are flush with the cut-stone pier under the tipple and are at the edge of navigable water. As they are in line with the tipple pier and in deep water they facilitate the movement of the barges and prevent them from grounding on the river bank.

The Pennsylvania R.R., whose lines follow the Monongahela River bank, has tracks underneath the tipple, while adjoining the railroad tracks is a street which branches into a wye directly underneath the tipple. The tipple crosses these on a single span having but one support, which is placed between the street and the railroad tracks.

Last winter the Vesta Coal Co. broke the ice in the river from Pittsburgh to Vesta No. 4 mine in order that river shipments might not be interrupted. Ice breakers were employed and the steamboat captains say the ice was 3 ft. thick at times. When the dam at one of the locks broke it lowered the water to such an extent that the barges had to be loaded to draw only 12 in. of water. This not only made transportation charges on the coal excessive, but what was more vital the requisite amount could not be handled. The Fuel Administrator in one day commandeered 400 carloads of coal in the freight yards at Connellsville for this company's use. The Jones & Laughlin Steel Co. at that period of car shortage used its own cars and locomotives on the Pennsylvania R.R. tracks for hauling coal from Vesta No. 4 mine.

A rubber belt conveyor line about 400 ft. long extends from the tipple at a level lower than that of the railroad tracks and parallel with them up to an elevation sufficient to load railroad cars. This conveyor line will handle the mine's capacity of production. A heavy electric motor with drums and cables, anchored to a concrete base, has been installed this summer to handle the loaded and empty cars after river navigation closes. As the coal is dumped at the rate of a 50-ton railroad car full in about 3 min. throughout an 8-hr. day, it is necessary to move the cars with ease and rapidity. No coal is shipped by rail as long as the river is open.

Between 2000 and 2800 mine cars of coal are dumped each day. These hold about three tons each, but if they are topped heavily four tons can easily be put on them. Two crossover dumps are used for discharging the cars. At each dump one man handles the dumping lever and hooks the ring on the car door, which automatically raises it as the car is tilted; another man removes the miner's checks; a third regulates the speed of the car by pushing or braking it as it moves toward the dump; another does nothing but work the lever that throws the switch, shunting cars to each of the dumps in turn; another man pulls the coupling pins as the cars move to the switch. He also shoves the coupling link to one side but does not remove it. Thus when the car strikes the one on the crossover dump and bumps it off, the coupling link is not in the way.

Chain Haul Pulls Trips to Dump

The loaded track is level or has only a slight grade as far as a chain haul, which carries them up a short grade about 10 ft. long. This chain haul is used to pull the entire loaded trip and feed it toward the dump, the coupling pins of the cars not being pulled until the cars are near the end of the haul.

At the top of the chain haul the switch is located which leads to the two dumps. The cars run from here to the dumps by gravity. They also pass by gravity through the dump onto the kickback at the end of the tipple and back onto the track for empties. Two kickbacks are employed, one for each dump. The cars are switched automatically by spring switches from both of these onto a single track for empties. A man is stationed at the kickback to give a stiff-moving car a shove and in general to prevent any tie up.

After passing through a crossover dump and kickback the empty cars have dropped, of course, to a low level. They are again raised by means of a chain haul. Here another man does nothing but couple the cars together as they come over the knuckle. The cars are oiled by a man who works between the loaded and empty tracks. The wheels on one side of the cars are oiled on the loaded track and those on the other side when the car returns on the empty track.

A 1-inch endless cable extends for 1500 ft. out from the tipple. This is guided by suitable guide sheaves and is driven by having four loops of cable passed around two grooved drums, placed tandem, the rope being in

contact with only half the circumference of each drum, the same as in the Whiting system of hoisting. An electric motor suitably back geared supplies the power.

This endless rope is used to move the trips of cars on the tipple. A special clutch is employed which grabs the cable and is coupled to the first car of a trip. As the cable moves the trip of cars goes with it; 120 to 140 cars are hauled at one time. As the cars are almost 10 ft. long each over all, a trip of cars is from 1200 to 1400 ft. in length. The tipple and steel bridge from the mine mouth to the river is about 3000 ft. long and 43 ft. high at its highest point, although the height is about uniform throughout its entire length. About 2000 ft. of this length is double-tracked. The right track is used as storage space for the loaded trip while being dumped and the left track for the empty trip of cars.

The coal from each crossover dump passes down through a crusher and thence moves by gravity to the barges on the river. In an emergency either crossover dump with its connected crusher would probably be able to handle the mine output.

Two scales are used for weighing the coal, one for each dump. They are placed between the crossover dumps and the switch on the loaded car tracks. A bridge about 12 ft. above the track carries two large rooms almost entirely inclosed with glass, one for each weighman, his scale beams and desk. As the cars pass over the scales on the track beneath, the weight is shown on the scale beams in the office on the bridge and is marked down on a weigh sheet. As the man at the dump removes the miner's checks from the car he files them on a spindle or needle-shaped steel wire passing through the hole in the check. The car checks are thus filed in the same order on this spindle as the car weights are placed on the weighman's sheet.

A clerk who has his station on the bridge coördinates all the car weights with the proper check numbers. He does this continuously throughout the day, not waiting until the day's run is over. A messenger carries the empty spindles from his desk on the bridge to the man taking the checks from the cars at the dump and returns with the spindle filled with car checks. As the weighmen's rooms are inclosed with glass it is therefore an easy matter for them to see what is occurring on the floor beneath.

Dumping 2400 cars in 8 hr. requires five cars to be dumped every minute continuously, making no allowance for time that may be lost. Such losses sometimes require that cars be discharged even more rapidly.

The material and supplies for the mine are delivered in railroad cars on the siding under the tipple. The mine cars are run alongside the railroad cars and loaded from them. Track of the proper gage is laid for the mine cars between the rails of the standard gage railroad track. The mine cars loaded with supplies from the railroad cars are moved on this track to a point directly underneath the side of the tipple, where a steel derrick capable of handling 50 tons is installed. A chain of sufficient strength is given one turn around the drawhead of the mine car and a hook attached to the chain, hooked over the top of the car end. One chain is placed on each end of the car in this manner, and the free ends of the two chains are fastened to a ring which is hooked onto the end of the derrick cable. The derrick hoists the mine cars from the railroad track up onto the tipple, a distance of about 40 ft. The cars are here landed on the track by two men.

The track on which they are landed is a spur from the empty car tipple track and is outside the tipple roofing. This allows freedom of movement overhead for the boom of the derrick to swing. The empty cars are lowered from the tipple to the railroad tracks in the same manner as the loads are hoisted. A 30-ton haulage motor used in the mine was easily and quickly raised from the railroad track to the tipple track by this derrick, the engine for which is placed in the lower part of the tipple, under cover.

Carbonization and Distillation of Peat

By M. Meredith
Liverpool, England

C. Galaine and C. Houlbert recently submitted a paper to the Paris Academie des Sciences on the carbonization and distillation of peat, sawdust, household refuse and other light organic products. The value of peat lies in the direction of distillation rather than combustion, and in these lines it could supersede wood in the production of acetic acid, methylated spirit, ammonia and tar, the basis of so many dyes.

In the process of distillation, peat, being a light material, requires larger retorts than coal, and these should be of a design that facilitates the transmission of heat from the surface toward the center. Experiments have shown that revolving retorts produce the best results. The apparatus devised and described by the authors is on the principle of the roasting appliances used for coffee, chicory, etc., but of course, with the addition of a receiver for collecting the distilled vapor, the great object being to provide an apparatus complete in itself for continuous and all-round operation.

This apparatus consists of six cylindrical retorts, each mounted on its own axis and capable of uniform rotation, while the individual cylinders are arranged in radial relation to a rotary central pivot, so that the retorts charged with peat can be entered into and withdrawn from a stationary semi-circular furnace in succession.

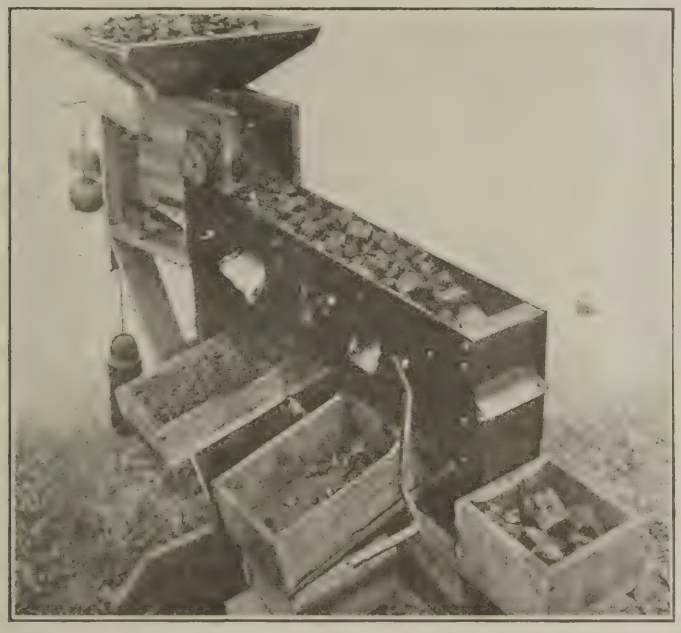
When the apparatus is in operation there are always three retorts undergoing distillation in the furnace, the other three being outside—one condensing, another being emptied, and the third recharging. The distillation takes on an average about 40 minutes for retorts holding a ton of peat and making six revolutions per minute.

To enable the gas arising from the carbonized peat to pass out of the retorts, the hollow shaft of each is perforated so as to provide a passage from the inside of the retort to a collecting chamber in the axis of the pivot and thence to the stills for fractional distillation. The rotary movement of the retorts insure rapid transmission of heat from the furnace, and as this heat acts on a large surface, the peat is uniformly carbonized in a short time at a relatively low temperature—a result which, it is claimed, it is impossible to obtain by the utilization of any other process.

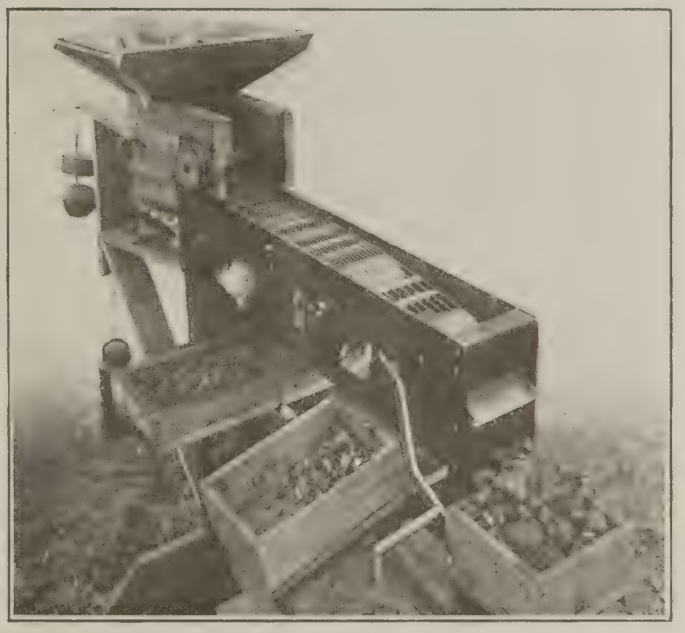
A New Type of Screen

By M. RAYMOND
Tiffin, Ohio.

SYNOPSIS — A modified form of the American system of rope transmission may be used for coal screening. This possesses many advantages, not alone confined to the screen itself.



PRESENT conditions make it imperative for coal production to be as efficient as human brains and brawn can make it. The economical value of sized and cleaned coal is clearly demonstrated by the premium placed on prepared fuel by the Government in this crucial period of American history. Therefore, anything that will contribute to the more efficient production of sized and picked coal should be brought to the attention of operators and tipple experts at once. The records of the Patent Office contain data on an invention that gives promise of introducing radical changes in tipple design and construction that will make for greater efficiency and economy in coal preparation.



Generally speaking, inventions are of two kinds. One sort is based on an entirely new idea or law in science or mechanics while the other is an adaptation of a familiar device to a new use with such modifications as the new use may indicate. It is those of the latter class that are so simple and so self-evident that we are often led to exclaim, "Why didn't I think of that?"

The particular device under discussion has its base in the application of the multiple rope drive to coal screening. No doubt a large majority of *Coal Age* readers have seen many rope drives where the driving wheel or sheave carries a large number of ropes which are taken off in groups to several driven sheaves. The driving sheave may send out 20 ropes to four or five different parallel lineshafts, each shaft taking as many ropes as its power load may require. If three shafts are in approximately the same horizontal plane and are arranged so that every alternate rope is wound around the sheave nearest the driver, while its neighbors on either side pass on to the next sheave, it will readily be seen that the spaces between the second and third sheaves will be twice as wide between ropes as the spaces in the section between the first and second sheaves.

Now let the ropes be wire cable with enough tension to keep them taut and prevent horizontal spreading or swaying and you have the underlying idea of the Landahl patent cable screen. The section between first and second sheaves is the slack screen; between the second and third is the egg screen, while the lumps pass over the end.

Of course, in practice there are refinements embodied in the actual machine that do not appear in the foregoing. These are the result of long careful study and experiment with the model, of which illustrations appear herewith. The model here pictured is built exactly one-twelfth the size of a screen designed for a capacity of 200 to 250 tons an hour, depending on the speed of the ropes. These refining details will best come out in a description of a typical three-track tipple, such as is shown in Fig. 3, while the results will in no way be inferior to the separations given by the model and shown in Figs. 1 and 2.

FIGS. 1 AND 2. SHOWING WORKING MODEL FULL AND EMPTY

Coal is received in the dump hopper, which is fitted with a flygate for bypassing to the inner track, where unpicked mine-run is to be loaded. If coal is to be picked and screened, a reciprocating feeder driven from the cable sheave tailshaft feeds the coal onto the first section of the screen, where slack falls through the narrow spaces between the ropes to a collecting chute. (In the model a tiny belt feeder is used.) The run-of-mine, however, contains big lumps, and these carry slack on their tops; the problem thus arises of spilling this from the lumps without breaking the big pieces by a jar or fall. This is accomplished by fitting three

of the idler shafts near the end of the slack screen with stirring cams, which turn or roll the lumps sufficiently to spill the slack off them without making more slack by concussion. A sketch of these cams, which rotate with the travel of the coal, is shown in Fig. 3.

Suppose it is desirable to pick both the egg and the lump—and this should be done more frequently than is now the case—all that is necessary is to put steel plates between the rolls, directly under the ropes in the next section. No separate belt conveyor or steel apron conveyor is required for picking. This may be done on the screen itself without the rather severe exercise of the optic nerve or muscle which accompanies the removal of refuse on a shaker.

In the egg screen, the process is similar to that in the slack section, with stirring rolls as before followed by a plain steel section of sufficient length to slide the lump into the chute over the outer track. All that is necessary to mix the various sizes as may be required is to run a scraper conveyor beside the screen from feeder to the lump chute and discharge the screened

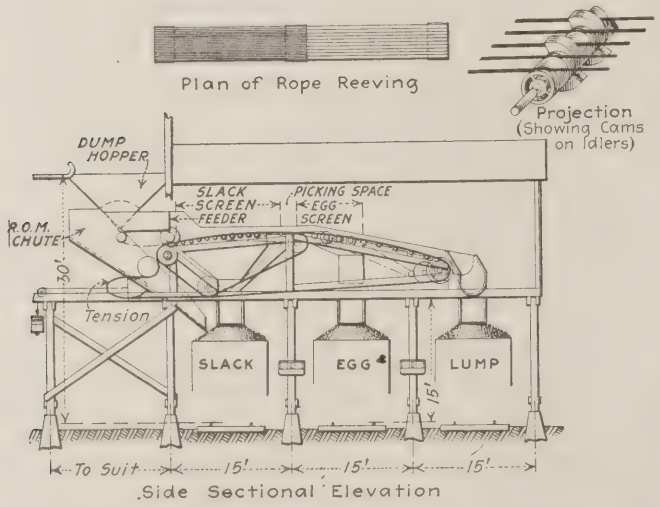


FIG. 3. TIPPLE PROVIDED WITH WIRE ROPE SCREENS

products into this conveyor for delivery with other sizes on either of the outer two tracks.

Compared to the ordinary forms of shaker screen, and even those more recent designs of shakers which have been brought out in the past few years, the Landahl cable screen has marked advantages in three directions—in the tipple structure itself, in cost, and in the minimizing of breakage. Regarding the first, there are two features which immediately appear, one of these being the saving in height. The screen is flat—indeed the tailshaft can be below the headshaft if advisable. This in itself will effect a saving in the size of the structure necessary. Then, again, no matter how carefully balanced a set of shaking screens may be, there is always vibration against which the building must be braced. Any pendulum with an oscillating motion, however smooth, will tend to vibrate its supports, and human ingenuity is not capable of producing two pendulums so accurate as to overcome this tendency when swinging in opposite directions, let alone the approximations which are customary in manufacturing shakers.

I have photographed interiors of many tipples and have often been unable to focus a camera correctly until the screens stopped running. With the Landahl screen this extra strength and rigidity of structure is entirely unnecessary, and any building that will stand up under the dead weight of the loaded screen is as strong as it need be.

The driving mechanism is correspondingly simple. There are no eccentrics or connecting-rods, no balance wheels and none of the elaborate mechanism sometimes seen to insure a forward travel of the coal over the shaker screen. All that is necessary is sufficient gearing to reduce the speed of the motor or engine to the proper speed of the driving sheave, and chain drives therefrom to the stirring rolls to assure their positive action. The only added feature is the tension, and this needs no extra room—it can be placed almost anywhere out of the way.

So far as breakage is concerned, the Landahl screen is nothing more than a smooth-running continuous conveyor and not a series of bumps which make up in the aggregate an intermittent progress. The coal does not drop so much as an inch during the screening or picking process. There are no breaks between upper and lower shaker, or at the point where the lumps fall into the chute or onto the loading boom. At the lower end of the cable screen there is a plate which fits closely up to the head sheave, onto which the lumps slide from the cables and from which they slide onto the loading chute or boom.

On the screen itself there is no breakage arising from lumps sticking in perforations only to be broken by the impact of a bigger lump from behind. The very construction of the screen itself guards against this. There are no edges or ends to the perforations against which the lumps may be crushed.

As to the cost, improved machinery usually is high in first outlay. Careful estimates based on actual expense show that the Landahl screen is at least 10 per cent. lower in first cost than a shaker screen outfit of the same capacity.

The screen here described was developed and patented by E. E. Landahl, who has had many years' experience in tipple design and who is at present assistant chief engineer of the Webster Manufacturing Co., in whose hands Mr. Landahl has placed the manufacture of this new adjunct to tipple equipment.

The volatile matter of bituminous coal would have greater economic value if converted into gas or liquid fuel than if burned under steam boilers. Under present market conditions heat in the form of coal gas brings 8 to 16 times the price of an equivalent amount of heat in the form of coal. Gas is extremely convenient fuel and can be used to advantage for many purposes such as cooking, lighting and heating buildings, municipal lighting, and in some industrial plants for obtaining a uniformly high temperature and clean products of combustion. The residue from the coking coals should find a ready market for house-heating and for steaming purposes. As both the gas and coke burn without smoke, their separate use would tend to make cities cleaner. The manufacture of gas from coal has been a commercial undertaking for many years and is still rapidly developing, the liberal margin between the price of heat in the form of gas and the price of heat in the form of soft coal making the conversion profitable.—*Bureau of Mines Bulletin No. 135.*

Use of Waste Gases for Steam Generation

By J. B. C. KERSHAW
Liverpool, England

THE general utilization of the waste gases from coke ovens and furnaces for steam generation has progressed rapidly in recent years, and had not the war checked development in many industries, still further progress doubtless would have been recorded. In view of the industrial struggles ahead, and the necessity that exists for utilizing our fuel resources to the greatest possible extent, it will be useful to study the progress and records of the past few years, to ascertain what economies are possible with the aid of waste-heat boilers.

THE heat carried away in waste gases may exist either as "sensible heat," that is, heat measurable by the thermometer and due to a failure to extract from the gases the whole of the heat generated by the combustion of the fuel, or as "potential heat," that is, heat represented by chemical energy. This latter is the result of incomplete oxidation of the combustible matter, and of the presence of hydrogen and carbonic oxide in the escaping gases.

In the latter case some form of burner or combustion chamber, with means for regulating the air supply, is necessary. When the waste gases carry only sensible heat, and combustion is completed, the addition of a boiler only is required to save some portion of the wasted energy.

In the earlier installations of waste-heat boilers the natural chimney draft was relied upon to overcome the increased resistance arising from the passage of the gases through the flues of the boiler. In many cases the boiler was erected directly above the furnace, in order to minimize the losses from this cause. This plan was never entirely satisfactory, and in modern installations artificial draft is always employed. In this way the draft of the original apparatus or furnace is increased rather than lessened by the installation of the waste-heat boilers. The use of fans furthermore enables much higher gas velocities to be attained over the water-cooled plates of the boiler, and increases considerably the rate of heat transmission and therefore the efficiency of the whole plant.

TABLE I. CHEMICAL COMPOSITION AND THERMAL VALUE OF WASTE GASES CONTAINING COMBUSTIBLE CONSTITUENTS

Type of Gas:	Per Cent. H	Per Cent. CH_4	Per Cent. CO	Per Cent. C_2H_4	Calorific Value*
Coke-oven gas	49.1	32.6	8.1	3.1	535
Blast-furnace gas	3.5	....	25.4	....	90 to 115

* In British thermal units per cubic foot of gas.

As regards the practical value of waste-heat boilers, it is possible with a modern plant to reduce the heat of the waste gases to 500 deg. F. Any furnace, therefore, which is allowing gases to pass away above this temperature may be provided with the necessary equipment for recovering the wasted heat, although as a general rule such recovery only pays when the gases are carrying 200 deg. F. or more of surplus heat up the chimney.

TABLE II. SENSIBLE HEATS OF WASTE GASES CONTAINING NO COMBUSTIBLE CONSTITUENTS

Type of Gas:	Temperature, Deg. Fahr.
Openhearth steel furnaces	1,100 to 1,300
Reheating furnaces	1,100 to 1,900
Cement kilns	1,300 to 1,800
Copper refining furnaces	1,400 to 2,200

In the United States it is calculated that the utilization of the waste heat from openhearth and other regenerative furnaces in the steel-making plants is equivalent to a saving of 250 lb. of coal per ton of ingots produced, or to an annual saving of two million tons of fuel. Of the total heat delivered to the openhearth furnace, 45 per cent. is wasted in chimney losses. From one half to two thirds of this heat can be recovered by the installation of waste-heat boilers.

Tables I and II show the chemical composition, thermal value and sensible heat of the waste gases from typical iron, steel and other metallurgical furnaces.

The following practical examples of waste-heat utilization for steam generation are drawn from the United Kingdom, Belgium, Germany and the United States; those are selected in which the data of test results are the most reliable and up to date.

Successful Plant in England

The Waste Heat and Gas Electrical Generating Stations, Ltd., was formed in 1907 to promote the use of waste heat for power purposes. This company has developed so satisfactorily, that it now controls nine of the waste-heat power stations running in the South Durham area. According to R. P. Sloan, who contributed a paper on the subject to the meeting of the British Association at Newcastle recently, there were 11 waste-heat power stations operating in the North East coast area. Two of these alone turned out 40,000,000 units of electricity per annum.

The waste-heat stations in the North East coast scheme operate in conjunction with the County of Durham Electrical Power Supply Co., and with the Cleveland and Durham County Electrical Power Co. The area served by these two power companies covers 1400 square miles, and the total power supplied at present is 343,000 hp. The waste-heat stations are placed close to the larger coke-oven and blast-furnace plants, and operate in parallel with the five main stations of the power companies. They are run at their maximum capacity, and all regulation of the power is effected by the main supply stations.

The main distribution and transmission system is three-phase, and the working pressure is 20,000 volts. The power is utilized chiefly in the machine shops and shipbuilding yards situated on the Tyne and Wear, and as the companies have a market for their current many times greater than the output of any individual waste-heat station, it is possible to run these plants continuously at their full capacity and to utilize to the best possible extent the machinery installed in them.

Unfortunately for scientific purposes, no figures have been published (or can be obtained) for the thermal or working efficiency of these North East coast waste-

heat stations, and therefore it is impossible to say how the system adopted compares in practical value and economy with the waste-heat stations situated in other countries. As the most notable and financially successful scheme of waste-heat utilization in the United Kingdom, however, the North East coast developments deserve first mention in any article on the subject.

In 1904 byproduct coke ovens were erected at the coking works attached to the Priestman collieries at Blaydon near Newcastle, and a complete installation of water-tube boilers was added in order to utilize the waste heat of the ovens. At Blaydon there are 90 ovens, and the steam produced from the waste heat is employed to generate electricity in an up-to-date power station, which is worked in coöperation with the Newcastle Electric Supply Co.'s stations.

At Rowlands-Gill there is an installation of 200 beehive ovens and in 1909 nine Stirling water-tube boilers were erected on the main flues which carried the waste gases from the ovens to the chimney. Two Bettington tubular boilers and four Stirling boilers fitted with under-feed stokers were added for the purposes of burning coke breeze and to provide an alternative source of steam power when the ovens were not working.

The electric power station at Rowlands-Gill contains four Westinghouse turbines coupled to three-phase alternators, generating current at 6000 volts for supply to the Newcastle Alloy Co.'s works in the vicinity of the generating station. This company has recently commenced the manufacture of ferrosilicon, ferromolybdenum, ferrochrome and ferrotungsten.

As regards the working efficiency of the Rowlands-Gill boilers, the following are figures given by A. D. Pratt in a paper read before the American Society of Mechanical Engineers (in New York) on Dec. 16, 1916:

Heating surface	1,610 sq.ft.
Gas weight	23,200 lb. per hour
Gas per square foot of heating surface	14.4 lb. per hour
Temperature entering boiler	1,720 deg. F.
Temperature leaving boiler	650 deg. F.
Drop in temperature	1,070 deg. F.
Horsepower developed	187
Approximate rate of heat transfer, per square foot per hour, per degree of temperature difference	4.7 B.t.u.
Draft (natural chimney draft)	0.56 in. of water

The test was made on one of the Stirling boilers rated at 161 hp. and worked in connection with 22 beehive ovens producing coke from an average of 3800 lb. coal per hour, or 173 lb. per oven per hour.

Belgian Waste-Heat Plant

The famous Cockerill Co., of Liege, started experiments in 1909 with the object of utilizing the heat contained in the waste gases from the large gas engines working with blast-furnace gas, the heat in these gases being estimated to amount to 2580 B.t.u. per horsepower-hour. The type of steam generator the engineers of the Cockerill Co. have evolved for the purpose consisted of a horizontal tubular boiler surmounted by a vertical tubular economizer. The gases which left the engine with a temperature of 446 deg. F. entered the boiler and were reduced in the economizer to 230 deg. F., while the water was heated up from 46 deg. F. to 338 deg. F.

The water then passed into the boiler, where it was converted into steam at a pressure of 114 lb. per square inch. Four boilers of this type had been installed by the Cockerill Co. before the war broke out and were developing 5000 hp. Steam was raised in the proportion of 1.93 lb. per electrical horsepower developed by the gas engine, and it was estimated that the boilers recovered 55 per cent. of the heat of the waste gases and increased the thermal efficiency of the gas plant by 13 per cent.

M. Greiner has calculated that with four gas engines of 1500 hp. each the savings effected by the installation of waste-heat boilers would amount to about $18,880 per annum. If it be accepted that a thermal efficiency of 30 per cent. can be obtained in the gas engine, then the addition of a waste-heat recovery apparatus would raise the efficiency of the entire equipment to 35 per cent., or to double that of the best steam plant.

An Illustration from Germany

As usual, most of the German records of trials and tests of waste gases for steam-raising purposes are more scientific and exact in their form than those of other countries. The most important and valuable of the results for comparative purposes are those recorded by Butow and Dobblestein in *Gluckauf*.

The data recorded related to trials with the Wefer patented system of boiler firing (with coke-oven gas), which was designed to secure a better mixture of the combustible gases and air passing into the boiler furnace, as well as to minimize the risks due to backfiring or to explosions in the mixing chamber. In the early types of burners for boilers fired with coke-oven gas, the gases were introduced by simple nozzles, air being supplied through openings in the furnace front. Imperfect mixing of gas and air led to imperfect combustion.

In the Terbeck burner a mixture of gas and air was obtained on the principle of the Bunsen burner, and a secondary air supply was introduced at the combustion point. By the use of this burner the steam output per ton of coal coked rose from 782 to 1320 lb., and the evaporation per square foot of heating surface per hour from 1.475 to 2.92 pounds.

In the Wefer system gas flows from the main into the 25 iron pipes feeding the graphitic burner tubes through a chamber, one end of which is formed by a hinged explosion cap. This uncovers the full section of the chamber in case of backfire and closes automatically when the latter has expended its force. It also affords easy access to the burner tubes. Air is supplied through a ring valve to a separate chamber, whence it flows concentrically with the gas tube for a distance, and is thus thoroughly mixed with the gas before ignition.

An eight-hour test on a double-flue boiler of 1280 sq.ft. heating surface gave the following results (summarized): Steam pressure (gage), 168 lb. per square inch; steam temperature, 592 deg. F.; mean gas pressure, 3.5 in. water; mean gas temperature, 80.6 deg. F.; mean calorific value of gas, 461 B.t.u. per cu.ft.; excess air supply, 1.71; evaporation, from and at 212 deg. F., 286.5 lb. per 1000 cu.ft. of gas; evaporation per square foot of heating surface, 4.47 lb. per hour; thermal efficiency, 79.2 per cent.

Forty-eight Wefer furnaces (in 1912) had been in satisfactory operation at the Victor Pit (Rauxel) for nine months. Assuming a boiler of 1290 sq.ft. of heating surface to yield 18,000 tons of steam during 300 working days, it is shown that the costs per metric ton of steam are: Wages ¾c.; maintenance and cleaning, ½c.; feed water, 1¼c.; interest and depreciation,

2½c.; total, 5c. per ton. This figure may be compared with the average estimate of 32c. per ton of steam in coal-fired installations.

Another series of trials carried out in 1914 with an improved form of the Wefer burner gave the following results, the tests being carried out on a boiler with the two flues fitted with the new burner: Heating surface, 1241 sq.ft.; gas analysis—CO_2, 1.6 per cent.; O, 1.8 per cent.; CO, 4.6 per cent.; H, 52.2 per cent.; CH_4, 28.8 per cent.; heavy hydrocarbons, 1.6 per cent.; N, 9.4 per cent.; mean calorific value, 428 B.t.u. per cubic foot; gas pressure, 5.8 in. water, barometer, 29.7 in.; flue gas analysis—CO_2, 8.30 per cent.; O, 3.24 per cent.; CO, nil; excess air ratio, 1.16; furnace temperature, 2560 deg. F.; steam pressure, 176 lb.; steam temperature, 567 deg. F. at the superheater; evaporation, 7219 lb. steam per hour; gas consumption, 24,854 cu.ft. per hour or 291 lb. per 1000 cu.ft. of gas, and 5.81 lb. steam per square foot of heating-surface per hour. The thermal efficiency, including superheat, amounted to 84.6 per cent. Loss by conduction and radiation was 15.4 per cent. Comparison with the earlier test data shows a net gain of 3.4 per cent. in thermal efficiency, despite the increase in evaporation from 4.47 lb. per square foot to 5.81 pounds.

In the improved Wefer burners used for these tests, the coke-oven gases flow from the gas chamber through 40 distributing tubes and are delivered about two thirds the distance along tunnels in the graphite burner block. The use of 40 distributing tubes in place of the 25 of the earlier burner secures a better mixture of the gas and air. The latter is admitted through a ring valve and flows concentrically with the gas tubes to the mixing chamber at the burner head. The original form of Wefer burner extended into the flue of the boiler for a distance of 2 ft., but the improved form is built onto a tubular extension of the furnace front, and thus the whole length of the flue of the boiler is available for heat transfer.

Provision is Made for Backfires

To provide for backfiring and explosions a central tube 8 in. in diameter is inserted in the burner, with a simple explosion valve on its outer end. The combustion chamber is lined with firebrick, and in order to promote more perfect combustion of the gases a perforated plate and a bank of short tubes of fireclay are mounted in the flue of the boiler. At the Victor pit, where these trials of the Wefer burner have been carried out, a gasometer with a capacity of 1,400,000 cu.ft. has been erected in order to secure a steady pressure of gas at the burners. As the gas is now being stripped of all its benzol in a byproduct recovery plant, the thermal value of the gas is not so high as it was at the time of the tests.

In comparison with the foregoing tests of the Wefer burner, figures given by Ortmann in the August, 1913, issue of *Stahl und Eisen*, covering the results of tests made with blast-furnace and coke-oven gases, may be quoted. The boiler used for blast-furnace gas had 968 sq.ft. of heating surface and was provided with an economizer. The thermal efficiencies in three separate tests were 79.4, 76.8 and 82.7 per cent., giving a mean of 79.6 per cent. The other boiler had a heating surface of 925 sq.ft. and showed in two separate tests efficiencies of 74.9 and 80.2 per cent. when fired with coke-oven gas, the mean in this case being 77.5 per cent. The calorific value of the gases and other details are not available in this case, so it is impossible to say whether the burner used was as efficient as the Wefer burner or otherwise.

Waste-Heat Utilization in America

A large amount of practical work upon the subject of waste-heat utilization has been carried out in America and in a paper presented at the 1916 annual meeting of the American Society of Mechanical Engineers, A. D. Pratt gives a review and summary of what has been achieved in connection with this problem.

The design and operation of boilers for utilizing the waste heat of openhearth steel furnaces, cement kilns, copper furnaces, beehive coke ovens, and heating furnaces generally, are discussed in this paper. From it the following particulars are abstracted concerning the waste-heat installation at the plants of the H. C. Frick Coke Co. at York Run, Penn., and of the Indiana Steel Co. at Gary, Indiana.

At York Run, 50 beehive coke ovens were connected to three Stirling boilers provided with standard type of baffles and 3600 sq.ft. of heating surface each. The test extended over a full week's run of 168 hours with an average of 44 ovens in service, coking coal at the rate of 13,800 lb. per hour, or 314 lb. per oven per hour. The weights of gas and temperatures varied considerably during the week, the lowest temperature noted being 1500 deg. F. and the highest 2075 deg. F. The exit temperatures varied from 475 deg. F. to 550 deg. F. and averaged 490 deg. F.

The gas consumed in this test, expressed as pounds per hour, was 83,650, and expressed as pounds per hour per square foot of heating surface, was 7.7. The drop in temperature of the gases in passing through the boilers was 1314 deg. F., and the horsepower developed amounted to 824, or 76 per cent. of the rated capacity of the boilers. The approximate rate of heat transfer was 3.2 B.t.u. per square foot per hour per degree of temperature difference.

The foregoing represents the results obtained with an early installation of boilers for utilizing the waste gases from beehive ovens. Later installations in the United States have shown considerable improvement upon these results.

At a more modern plant, provided with a specially designed Babcock & Wilcox boiler, 18 sections wide, each section made up of 26 twenty-foot tubes, and thus providing 10,200 sq.ft. of heating surface, the draft is furnished by a turbine-driven induced-draft fan, and a much higher rate of heat transfer is obtained, due to the greater speed at which the gases are passed through the boiler. The results of two tests with this boiler were as follows:

	No. 1	No. 2
Gas consumed, pounds per hour	125,500	155,100
Gas per square foot of heating surface per hour	12.2 lb.	15.2 lb.
Temperatures:		
Inlet to boilers	2,329 deg. F.	2,158 deg. F.
Exit from boilers	463 deg. F.	477 deg. F.
Drop in temperature	1,866 deg. F.	1,681 deg. F.
Power developed	1,750 hp.	1,956 hp.
Per cent. of rated capacity of boiler	172	192
Approximate rate of heat transfer *	5.6	6.8

* Expressed as B.t.u. per square foot per hour per degree of temperature difference.

The performance of this first boiler has been so satisfactory that six additional units have been ordered by

the owners of this coking plant, the only difference being that there are 27 sections instead of 18, and that each boiler possesses 15,300 sq.ft. of heating surface, equivalent to a capacity of 9180 hp. for the six units.

The utilization of the waste heat from openhearth steel furnaces has been practiced for many years in the United States, and according to Mr. Pratt (see paper previously quoted) there are already installed, or on order, boilers capable of producing 90,000 hp. from this type of waste heat alone. These boilers are connected to 190 openhearth furnaces which produce annually over nine million tons of steel. Experience has shown that through the use of these waste-heat boilers the net cost of production is reduced by 20 to 25c. per ton, and that a total economy of $1,840,000 is earned on the foregoing output of steel. The fear that the installation of waste-heat boilers, with their fans and other accessories, would cut down the production of the openhearth steel furnace has proved groundless, for the figures show that the improved draft resulting from the use of fans leads to a reduction in the time required for the separate heats and increases the tonnage capacity of the furnace.

The installation of waste-heat steam generators at the Gary works of the Indiana Steel Co. consists of 28 special six-drum Rust-type of boilers, equipped with special cross-baffles, in order to give the desired gas velocities over the heating surfaces. Each boiler has a heating surface of 4880 sq.ft., and the one to which the following test relates developed 393 hp., or 80.6 per cent. of its rated capacity.

Gas weight, per hour	83,434 lb.
Gas per square foot of heating surface per hour	17.1 lb.
Temperatures:	
Entering boiler	1,155 deg. F.
Leaving boiler	530 deg. F.
Drop in temperature	625 deg. F.
Draft at boiler inlet	1.47 in. water
Draft at boiler damper	3.95 in. water
Loss in draft	2.48 in. water
Approximate rate of heat transfer, square foot per hour per degree of temperature difference	6.92 B.t.u.

Philippine Coal Fields Develop Slowly

From the *Consular Reports* the following notes on the Philippine coal fields are taken, a map being added so as to enable the reader to locate the points mentioned:

"C. H. French, the new manager of the National Coal Co., has just returned from a tour of inspection of the company's property near Zamboanga and gives a favorable report. The company is not yet turning out any coal, but has finished the preliminary survey of the field and expects to be prepared in six months to put out coal in a small way pending the adequate development of the project. The preliminary output will probably not exceed 100 tons per day.

"The Sibuguey Peninsula, on which the National Coal Co.'s fields are located, contains approximately 100 square miles, all of which appears to be well underlaid with coal. The company is devoting its attention at present to an area about 10 miles square, which is especially rich in deposits. Of this tract some 4 square miles are fairly well located for immediate development work. This portion of the tract lies near the small Sibuguey River that is navigable eight or nine months of the year and will supply transportation facilities to Taba Bay pending the construction of the necessary railroads. [Sibuguey River and Peninsula and Taba Bay do not appear in modern atlases.—Editor.]

"It is the intention of the company's management to open up this tract provisionally and to get out as much coal as possible for immediate local needs while the more systematic development work is going forward. Under the present transportation conditions it will be impossible for some time to get the necessary trackage and rolling stock for the railways, and the same will be true of much other modern machinery required. Meanwhile, however, a considerable amount of coal may be taken out near the river and transported to ocean-going ships.

"The preliminary survey of this field shows the presence of considerable anthracite on the northern end of the coal-bearing tract. One vein of this, 13 ft. thick, has been uncovered sufficiently to show an extensive deposit. No attempt will be made to exploit the anthracite at present, as the islands are not prepared to use this class of fuel.

MAP OF PHILIPPINE ISLANDS

"Near the middle of the tract a 6-ft. vein of good bituminous coal has been found. Tests have shown the product of this vein to be good coking coal, considerably above the standard required of Japanese coal in this market. Another vein of noncoking coal has been located and explored to a considerable extent. The coal from this is of good quality and compares favorably with the Japanese product consumed in the islands. Two private operators are turning out coal on the island of Cebu. The Uling Co., whose mine is

situated south of the city of Cebu, and the Banao Co., whose plant is to the north of Cebu, claim to be turning out about 30 tons each per day. Their average output is probably considerably less than this amount at present. Their product is said to be of good quality, and they have no difficulty in selling all they can produce. The deposits at these places are said to be extensive. No data are available on which full reliance may be placed, as no official surveys have been made.

"On the island of Batan (not to be confused with the Province of Bataan on the island of Luzon), the Betts Coal Co. is turning out an average of 10 tons a day. All of this output is being consumed by the Legaspi line of the Manila R.R. No complaint as to the quality of the coal is made by the railroad, but the amount produced is not sufficient to meet the needs of the line.

"For the purpose of beginning operations as soon as possible the National Coal Co. has recently purchased some equipment from the Manila R. R. Co., including some engines, boilers, tackle and pumps. The company's engineer has recently resigned, and operations will be temporarily suspended pending the employment of another man with coal-mining experience. Such a man does not appear to be available in the islands at present, and it may be necessary for the company to send to the United States for him."

A Neglected Coal Field in West Virginia

THE recent increased demand for so-called smokeless coal has led to new investigations for such coal in fields along the eastern margin of the great Appalachian coal field, and particularly in the regions nearest tidewater. One of these, known as the Abram Creek-Stony River coal field, in Grant, Mineral and Tucker Counties, West Virginia, has recently been examined by geologists of the United States Geological Survey, Department of the Interior, which makes public the following statement:

The fields examined include the southeastern prong of the southern extension of the famous Georges Creek field of Maryland. The southwestern prong extends up the North Fork of Potomac River and over into the headwaters of Cheat River. At the north end of the Georges Creek field there is a single basin, the axis of which nearly follows Georges Creek across Maryland from Wellersburg, Penn. This axis passes a little east to the North Fork of the Potomac almost to Elk Garden, where it swings farther eastward and follows Abram Creek up to its head and thence passes southward a little east of the upper waters of Stony River across the divide into the basin of Red Creek, in Tucker County. The basin ends a few miles south of the South Fork of Red Creek. The southeastern and southwestern extensions of the fields are separated by the Canaan Valley anticline, which follows Canaan Valley northward nearly to the Falls of Stony River, then turns northwestward, crossing the North Fork of the Potomac not far from Stoyer. The northern part of Georges Creek-Elk Garden basin as far south as Emoryville is well known, but almost nothing has been published about the southern part. Around Elk Garden there are the remnants of the Pittsburgh coal, which in that region has a thickness of 12 ft. or more. This bed occupies only the hilltops and is now nearly worked out. Most of the present mining on it is done with steam shovels on the outcrop coal. Below the Pittsburgh, however, lie three beds that are widely minable in the area considered—the Barton bed, almost 400 ft. below the Pittsburgh; the Thomas bed, nearly 200 ft. lower; and the Davis bed, nearly 200 ft. below that.

As the recent field work has shown that the correlations of the coals given in the Survey's Piedmont geologic folio, published in 1896, are in many areas erroneous, and that the structure mapped in that folio does not quite agree with the structure as now determined, the following statement is made pending a more detailed report and map.

The Barton, Thomas and Davis beds crop out at the mouth of Abram Creek at Harrison, but between Harrison and Emoryville the Thomas and Davis beds pass below drainage level. From Emoryville to the Mount Storm-Petersburg road the Barton coal keeps a short distance above drainage level, and the other two beds lie below drainage level all along Abram Creek. The Thomas and Davis beds rise above drainage level near Bismarck. All the coals lie above drainage level at the mouth of Stony River, but the Davis coal goes below the level of Stony River about 3 miles from its mouth and the Thomas coal comes down to river level at the big bend north of Mount Storm. South of the Northwest Turnpike the Thomas coal is about at the level of the river, but it rises above the river still farther south, and about 3 miles below the Northwest Turnpike crossing of Stony River the Davis bed also rises above the river and continues to a point about three-quarters of a mile above the falls, where it again goes under. The Thomas bed keeps well above the river from the Northwest Turnpike to the mouth of Stingley Run, where it is just above the level of the river. From there southward all the coals rise, so that the Davis coal is above the river level a short distance above the mouth of Helmet Run. All the coals underlie the divide between Stony River and Red Creek and crop out in the upland divides between the branches of Red Creek. This basin is fairly flat, but its edge is sharply upturned on the east and less sharply upturned on the west.

The two upper beds, the Barton and Thomas, are similar in having usually one bench of clean coal, from 20 to 40 in. thick, overlain by a bench of mixed bony and good coal. The Barton coal differs, however, in having a parting near the bottom of this main bench of coal, and the coal below that parting is poorer than the rest of the bench. The Davis coal is generally much thicker, reaching in places a thickness of 9 ft., and there is usually a principal shale parting near the middle or above the middle and minor shale or bony partings in the two benches above and below the main parting. The Barton and Thomas beds will yield about 2½ ft. of coal and the Davis bed from 3 to 6 ft., the thickness depending on the number of smaller benches taken.

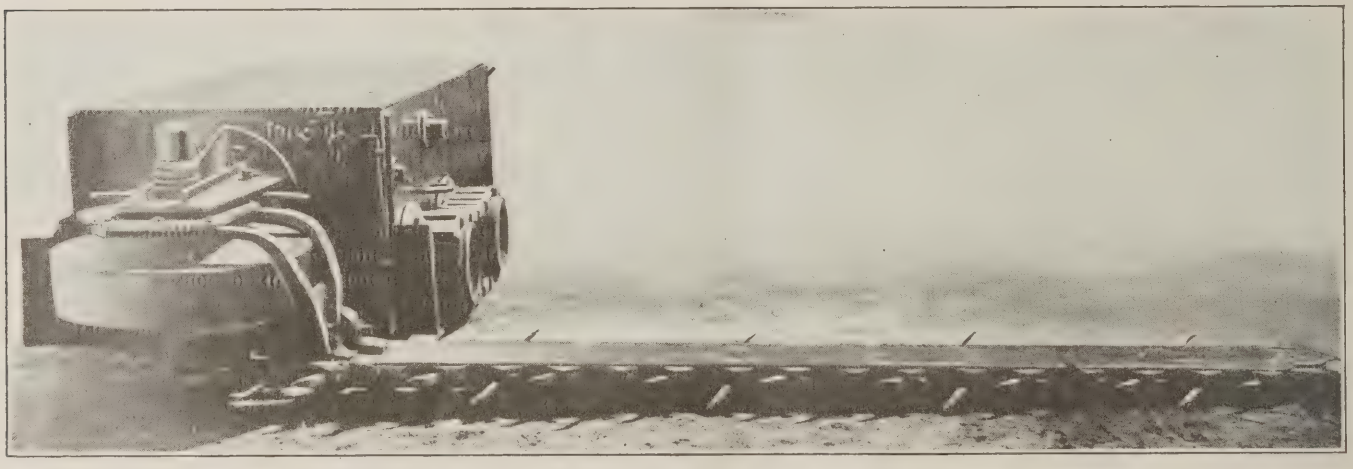
The coal of this field is much nearer tidewater than the so-called smokeless coals of Somerset, Cambria or Clearfield Counties, Pennsylvania, or the New River or Pocahontas coals of West Virginia. On the other hand, it is not generally as thick, or, if as thick, it is more broken up by partings than the smokeless coals of the regions mentioned. On this account it will be more difficult to mine and greater care will be necessary to obtain high-grade fuel. Furthermore, the average of many anaylses of the coal indicates that it contains a larger percentage of both ash and sulphur than either the New River or Pocahontas coals and more than that in most of the coals now mined north of this field.

The following estimates of the coal content of the three principal beds are based on the correlation of the beds made in recent field work: Assuming a recovery of 1200 tons per acre-foot, the Barton coal bed, with an estimated recoverable thickness of 30 in. and an available area of 19,200 acres, will produce 57,600,000 tons; the Thomas bed, with an estimated recoverable thickness of 30 in. and an available area of 45,880 acres, will produce 137,640,000 tons; and the Davis bed, with an estimated recoverable thickness of 36 in. and an available area of 63,200 acres, will produce 227,520,000 tons—a total of 422,760,000 tons.

New Apparatus and Equipment

New Mining Machine

The Brantley Coal Mining Machine Co., of Sand Springs, Okla., has placed upon the market the Brantley coal cutter. This machine, shown in the accompanying illustration, is claimed by the inventor to possess all the advantages of both the longwall and shortwall machines, as well as some others all its own.



As may be seen in the illustration, the machine consists of an electrically operated mechanism driving a chain carrying pick cutters. The cutter bar, which may vary in length from 5 to 10 ft., may be swung in all directions and will cut at any angle to the body of the machine. Thus any kind of a cut desired may be made.

The truck upon which the coal cutter travels is made integral with the body of the machine, since due to the universal movement of the cutter bar there is no necessity for removing the machine from its truck. Propulsion is secured by means of a combination of track wheels and caterpillar chain. The machine will thus travel either upon rails or upon the floor of the mine.

The body of the machine is 6 ft. long, the height over all is 28 in. and the track gage is 36 in. The height of the kerf is 4 in., and timbers may be set within 4 ft. of the face. This coal cutter has three cutting and three traversing or traveling speeds. The cutting speeds vary from 2½ to 4 ft. per minute, while the traveling speeds range from 2½ ft. per minute to 4 miles per hour.

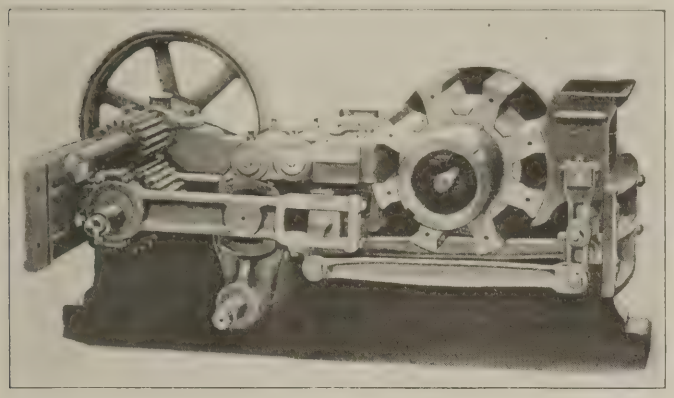
The arrangement of the propelling device is such that the machine may be made to turn itself around as if it were on a pivot. It will cross or leave the track at any desired point regardless of the position of switches. It may thus be used to advantage for driving either rooms or headings, air courses or breakthroughs.

The inventor of this machine has also developed a device for loading the coal onto mine cars as fast as it is cut by the machine. It is claimed that the coal cutter will mine coal as rapidly as 12 men could mine it with picks. If the loader will place this coal in a car as fast as the cutter will undercut it, it would appear that the combination of the two would do much to relieve the present shortage of labor in the coal mines.

MANY ADVANTAGES ARE CLAIMED FOR THIS NEW COAL-CUTTING MACHINE

Michaelsen Briquetting Machine

By L. Klebba
Minneapolis, Minn.



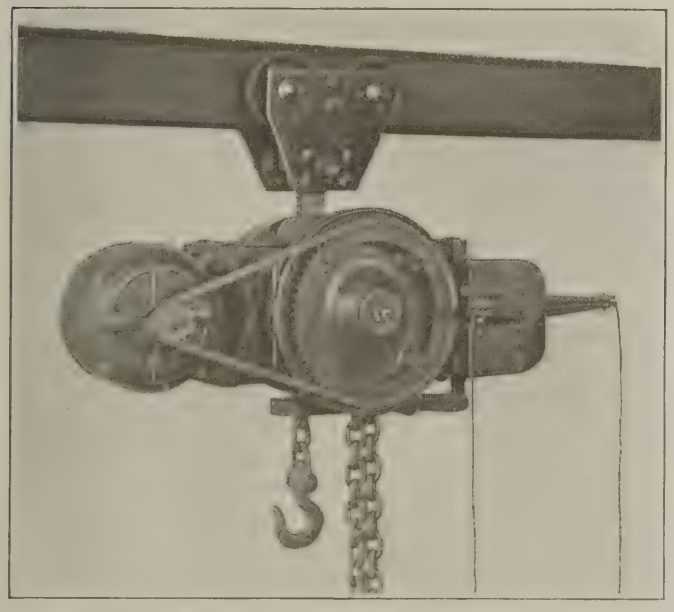
A new briquetting machine has been designed and patented by Private William P. Michaelsen, Co. C, 326th Field Signal Battalion of the United States Army. This machine is designed to press either granular or fibrous materials such as peat, lignite, coal dust, sawdust and the like into bricks or briquets suitable for fuel. In this process the machine differs considerably from others built for the same purpose.

As may be seen in the accompanying illustration, the machine consists of a revolving "cylinder" containing eight molds. This at one side revolves past a feed hopper from which each mold in succession receives a charge of the material to be briquetted. The cylinder is revolved by a succession of steps, each movement bringing one chamber or mold in front of the compressing plunger. This plunger then makes its stroke, compressing the contents of the mold in front of it into a briquet.

The bottom of each mold contains a movable piece carrying a plunger. When the chamber reaches its lowest position this plunger is acted upon by a cam inside the cylinder. The cam forces the bottom of the mold outward, pushing the pressed briquet loose from the walls of the mold. Upon a further movement of the cylinder the ejector plate is returned quickly to the bot-

tom of the mold by the action of a spring on the pin after this pin has been released by the cam. The briquet is thus ejected from the mold.

As may be seen, the feed hopper or block is made heavy and has a movement exactly opposite to that of the compressing plunger, so that the force of the



MICHAELSON BRIQUETTING MACHINE

plunger pressure is resisted not alone by the cylinder shaft but by an opposite pressure from the feed block as well. Any suitable means such a a chute or a conveyor may be employed to feed the material to be pressed to the machine. In like manner similar means may be utilized to remove the finished briquets from it. It would appear that this machine would find its greatest application in making large briquets of soft or fibrous material such as sawdust or peat.

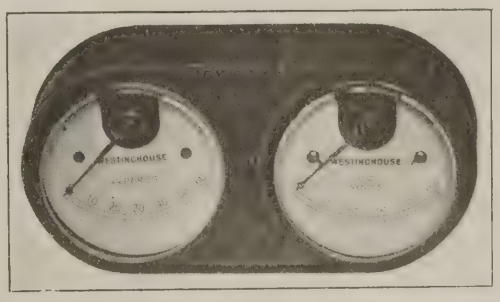
Small Electric Hoists

Small electric hoists that are adapted to almost every kind of work involving hoisting form an economical means of handling loads of from ½ ton to 5 tons. These

SMALL ELECTRIC HOIST FOR GENERAL USE

machines can lift with from 5 to 10 times the speed of a hand-operated chain hoist, and their cost is but a fraction of that of an electric traveling crane. They can be suspended from a fixed point, shear-pole, jib-crane trolley running along an overhead track, or small traveling crane. The trolley or crane when used can either be pulled along by hand or operated by means of a motor.

These little hoists are controlled from the floor by means of pendant ropes. A brake, which is automatically applied when the controller is returned to the off position, holds the load suspended, and a safety switch automatically cuts off the current when the hook reaches its safe limits of travel.



Special mechanical and electric features are employed in the construction of the motors to suit the service. The direct-current motors are modifications of the series-wound crane type. The alternating-current motors are of the polyphase squirrel-cage type with high torque, rotor windings. Motors of ¾ hp. are used for ½-ton hoists and 7-hp. motors for 5-ton hoists, the ratings being figured on a 30-min. basis.

The controllers of the drum type are designed to break heavy currents without burning the contacts. When the tension on the control ropes is released a spring returns the controller to the off position.

The hoist illustrated is built by the Yale & Towne Manufacturing Co., and equipped with Westinghouse electric apparatus.

New Duplex Instruments

The Westinghouse Electric and Manufacturing Co., of East Pittsburgh, Penn., has recently placed upon the market two new duplex instruments for battery charging, marine, dental, telegraph, telephone, farm lighting and other compact instrument panels where direct cur-

INSTRUMENTS MOUNTED IN METAL CASE

rent is involved. These duplex instruments consist of any two standard Westinghouse type AW or type FW instruments desired, mounted in an attractive dull-black metal case. The type AW instruments have round open faces, 3 in. in diameter, with glass cover and rear mounting studs; the type FW have 5-in. faces.

During the past 15 or 20 years considerable attention has been given to designing of furnaces that would burn bituminous coals without producing smoke. Campaigns have been conducted to educate the fireman and induce him to use proper methods of firing the coal so as to produce the least amount of smoke. Large cities passed smoke ordinances aiming to reduce the smoke by encouraging or forcing the coal user to install apparatus that would burn coal smokelessly. These methods of attacking the problem have had much success but the production of unnecessary smoke continues. A large part of this smoke is made in a way that can not be easily controlled, even with good intentions on the part of the offenders.—*Bureau of Mines Bulletin No. 135.*

Anthracite Mine-Cave Situation

FOR many years the people living in the anthracite region have been keenly alive to the necessity of obtaining some compensation for those whose surface property has been destroyed by mining operations. Similar controversies have existed in most of the important coal states and, in fact, wherever mining has been carried on under valuable surface holdings, either farmland or property otherwise improved. The solution of the Scranton mine-cave problem has, therefore, more than local interest. Problems of like character confront more or less the whole anthracite field, and the methods proposed and adopted in that region may be applicable wholly or in part to other sections of the country.

IN THE early days of the City of Scranton prominent members of the Scranton family acquired large holdings where the present City of Scranton now stands. A part of this property, that on the mountain to the southeast, contained iron ore. This fact and the abundance of coal in the region caused the Scrantons to organize the Lackawanna Iron and Coal Co. In 1841 the first furnace of this company was fired, and while the local ores proved a total failure, the project greatly encouraged the anthracite industry in the vicinity and had much to do with the early development of Scranton.

In 1851, to bring supplies to the furnaces and mills and to ship products out to markets, railroads were built extending east and west from Scranton. This was the beginning of the Delaware, Lackawanna & Western R.R. It was in these early days of the coal industry that the Scrantons began to dispose of some of their surface rights. It is stated that at first purchasers of land were given deeds in which merely the mineral was reserved. After a limited number of such transfers were made this form was discontinued; the next deeds reserved the mineral and also the right to mine it. This form was again soon modified so as to reserve to the mine owner the right to mine out all coal beneath the surface in question without liability for any damage which might result therefrom. This reservation has been held by the supreme court of the state to be valid. It is said that most of the deeds of sales for Scranton property are written with this latter clause, which waives for the grantee the right of surface support.

Area in Which Coal May Not Be Mined

In early transfers of property a tract was set aside for the business center of the city. No coal can ever be mined under six blocks to the east of the river. Thus the safety of the big office buildings of the city is assured. The original streets also were protected similarly, but those opened up later were not. Furthermore, in case of damage to their property the public-service corporations do not have any recourse in the wording of the original deeds.

As mining progressed in the different regions of the anthracite field and the workings became more extensive, difficulties with owners of surface property increased proportionately. Matters finally reached such a stage that a commission was appointed by Governor Tener during the legislative session of 1911 to investigate and report on the whole matter. This commission was made up of men prominently connected with the mining and engineering professions; it held many sessions in different parts of the anthracite field and made its report in March, 1913. The anthracite press commenting on this report at the time stated that in its opinion the commission had found a solution of the difficult mine-cave problem, at once prompt and effective as well as equitable to all the parties concerned.

That solution rested on certain voluntary, yet substantial, concessions which the principal mining companies of the anthracite coal region declared themselves willing to make to the surface property holders. They were willing to pay at least 50 per cent. of all the injuries suffered by structures in the progress of mining, where such structures are of a value of $5000 or less. This concession, conservative as it seems, was regarded as being liberal, for the assessment books of Scranton showed that more than 90 per cent. of the structures of the city were assessed at less than that amount and would be entitled to the compensation offered. The owners of structures exceeding $5000 in value were privileged to buy sufficient pillar coal for support of their premises at a rate not to exceed 25 per cent. above the prevailing royalty value at the time of purchase. This meant about 35c. a ton for pillar coal. It was also provided that the mining companies would erect artificial supports in the mines if the surface owners so desired—the expense of the work, however, to be borne by the surface owner. In case any disagreements were to arise between the interested parties, provision was made to refer the matter to a board of three commissioners. This agreement was signed by the presidents of the several companies which controlled more than 90 per cent. of the coal operations in the anthracite field.

During the years following this report much legislation was attempted in which politics played a prominent part; in fact the mine-cave situation was made the football of politicians. In the Scranton municipal election last year it was again a prominent issue. After the present mayor, A. T. Connell, was elected matters were taken up in earnest and the proposition referred to later in this article was put in shape. On July 22, 1918, the anthracite concerns operating mines under Scranton and Dunmore made a proposal to the people of Scranton through the Mine-Cave Committee of the Civic Bureau of the Scranton Board of Trade. On July 24, 1918, that body addressed the following communication to the authority by which it was appointed:

At a meeting of this body, held June 25, 1917, a resolution was passed authorizing the chair to appoint a committee of five for the purpose of meeting representatives of the anthracite coal companies operating in this vicinity, the purpose being to determine whether some practical arrangement could be reached which would relieve the surface owners and residents of the community to a large degree from the fear and distress arising from the fact that mine caves were occurring from time to time in certain parts of the city. During the past 13 months the committee has held 29 stated meetings and numerous informal conferences, most of them in this city, with several in New York. After your committee had held several meetings a joint conference was held in the Board of Trade rooms in this city. At

this conference the members of the committee carefully outlined to the anthracite operators the so-called "mine-cave problem" as it appeared to them, and suggested that it might possibly be approached from two different angles. First—either a special arrangement or contract could be made between each particular town or city affected and the companies operating in that community; or second—a comprehensive plan could be outlined which would apply to the problem wherever it occurred throughout the coal fields and one to which the anthracite interests and all the inhabitants of the entire region, and possibly the Commonwealth of Pennsylvania, also might be parties.

Much time was devoted at this conference to analyzing the advantages and disadvantages of the two plans suggested. The operators directed the attention of the committee to an announcement published in the Scranton papers on June 23, 1917, whereby the coal companies subscribing agreed to do certain things voluntarily and requested that the committee state in what respects this proposition was not satisfactory to them. The attitude of the operators at this meeting indicated very clearly that the voluntary agreement was the only plan they could see their way clear to seriously consider, and this impression was confirmed in subsequent meetings. On Monday, July 22, 1918, your committee received from the operators a voluntary offer or agreement, duly signed, and this we are prepared to announce for your consideration.

After submitting their proposal, the representative of the operators offered an explanatory letter, addressing it to the chairman of the Mine-Cave Committee of the Civic Bureau. Extracts from this letter follow:

In accordance with your request, I inclose herewith our proposal, duly executed by all of the companies who have been represented by our committee. If the same be acceptable to your committee, we will prepare and submit to you a proposed form of contract between the commission to be appointed and the coal companies, binding them legally to the terms of the within proposal, which we will forthwith put into effect. As to schools, our position has been that there is no reason why we should bear the whole burden of their protection. In Commonwealth vs. Citizens Coal Co., 256 Pennsylvania, at page 331, it is held that the school boards have the right to condemn the coal necessary for the support of the schools, and they also may purchase the same under the plan proposed, at a price to be fixed by the commission. In all cases where the school boards act, either by instituting condemnation proceedings or by filing an application before the commission, we will immediately discontinue all mining which might endanger the safety of school buildings, pending the determination of the questions of what support should be provided and the cost thereof. We, as taxpayers, will pay some 20 per cent. of all such awards. Our committee is unanimously of the opinion that this burden can be, and should be, fairly borne by taxation. Notwithstanding all we have read and heard of sentiments to the contrary, we have faith in the sense of fairness of the citizens of Scranton, and that they appreciate the difficulties and mutual obligations relating to the mine-cave problem. We believe the plan proposed will be reasonably acceptable to them and, with such modifications as experience may prove to be helpful, a permanent and satisfactory solution.

The proposal referred to follows:

At the request of the Pennsylvania Anthracite Mine-Cave Commission, a voluntary undertaking was made by various mining companies under date of Feb. 19, 1913, which was supplemented by a public announcement made June 19, 1917. As the result of numerous conferences with your committee, we have offered not only to bind our respective companies substantially to the obligations named in the foregoing, but to assume additional burdens as stated in our communication to your committee of Apr. 4, 1918. You now ask us to formally restate these offers in a written proposal.

The committee representing the coal-operating companies of the City of Scranton who signed such communication of Apr. 4, therefore, hereby submit the following proposal as a present adjustment of the mine-cave problem.

A large part of the surface upon which buildings have been constructed in the City of Scranton has been granted by deeds which expressly reserved the right to mine the coal thereunder without liability for surface damage. The legality of such reservations has been repeatedly upheld by the courts. In the development of the coal-mining industry the mining companies either constructed themselves or permitted the construction of homes for the workmen engaged therein, upon the surface over the mines, reserving, however, the right to remove all the coal when in the orderly process of mining the same became necessary. To the extent that they encouraged or permitted such construction a moral obligation may be attributed to them either to maintain such homes or to provide others. They are also very largely interested in the prosperity of the City of Scranton. Upon these grounds they have been and are disposed to voluntarily accept certain specific obligations.

On the other hand, it is essential to their continued existence that they be permitted to mine substantially all their coal. Indeed, such obligation has been, in many leases, legally assumed. Efforts have been made to obtain legislation which, if upheld by the courts, would have seriously interfered with mining operations, would have restricted the extent of the coal they might mine, to the detriment of the anthracite communities and the consuming public, and which even sought to penalize both the companies and their employees. The advocates of such legislation have been the very persons who have accepted the restricted deeds and who have sought to thereby obtain rights which they were not in law entitled to. The disastrous results which might ensue not only to the industry, but the City of Scranton, were not considered. It may not be generally known that the wages paid by the coal companies engaged in Scranton in the production of coal amount yearly to more than $15,000,000, a sum in excess of the aggregate of all other wages paid for all other work in that city.

Welcomed Appointment of Committee

We have, therefore, welcomed the appointment of your committee by the Board of Trade. We believe that our interests are altogether mutual, and that it is most advisable that some plan be adopted immediately, even though it does not fully measure up to your views of our obligations. You will appreciate that any legal obligation voluntarily assumed by us involving serious additional pecuniary burdens must be conditioned upon our freedom to exercise our present legal rights to mine our coal. We have, therefore, repeatedly stated and again advise that this proposal shall remain in effect so long and so far as the exercise of our rights to mine coal are not restrained, restricted or penalized by the passage or enforcement of state laws, municipal ordinances or court decisions. This does not mean that we will withdraw our proposal because of individual litigation which does not result in a general and material restriction of our rights to mine coal or because of efforts which may be made to obtain legislation.

With this preface, we propose: First, A commission of three shall be appointed by agreement of our committees, the salaries and all expense of which shall be borne by us. In case of any vacancy in the commission the same shall be filled by like agreement between the committees to be appointed by us and by the Board of Trade. It shall be the duty of the commission to coöperate with us and with the public both to prevent accidents which might result in personal injury and to minimize damage to property. Its members will be expected to become familiar with mining conditions and to be able to give expert advice to the people, the school boards and city officials. The commission will also be charged with the duty of determining, as between the different companies, the responsibility for surface damage; the value of structures damaged; whether the same have been satisfactorily repaired by the companies, or, if the owner desires to do his own repairs, what compensation should be made to him therefor. It will also be given jurisdiction to determine similar questions in the event of damage to streets. If it determines that pillar coal should

be sold for support it will finally determine such a valuation of the same as shall fully compensate the coal company therefor. It shall be vested with jurisdiction upon the application of an owner or lessee of property who desires to build a dwelling, after a hearing upon notice to any mining company owning or having any interest in the coal under the surface upon which such dwelling is proposed to be constructed, to certify in writing that the surface upon which such building is proposed to be constructed is reasonably safe with respect to the danger of surface subsidence within a period of 20 years thereafter. It will be expected to adjust any disputed questions which may arise between the companies and the owners of property. It will also have the custody and expenditure of the fund hereinafter provided for. A written contract shall be entered into between the commission and the coal companies, which shall be approved by your committee, and which shall expressly vest in it the powers above outlined, together with the right to enforce by suit against one or more of us the obligations we assume in this proposal.

Second, As to public highways and city streets. The principle of conservation of the coal under such highways and streets for market purposes is to be accepted where no serious public injury will result. The companies are to provide for the security and convenience of the public by giving proper notice of proposed mining under streets which may affect the surface by providing temporary ways of passage, and by repairing at their own expense any and all damage to streets or municipal structures therein. The companies are to be bound absolutely to promptly restore all streets to as good condition as before any damage except as to structures of individuals or private corporations therein or thereunder, and to indemnify the city against liability. Subject to the foregoing any and all disputes which may arise in connection with the mining of coal under public highways and city streets are to be finally determined by the commission.

Would Restore Buildings Valued Less Than $5000

Third, In case of damage to existing buildings or to dwellings occupied as homes constructed within the next 20 years at locations certified as reasonably safe by the commission as hereinbefore stated within the City of Scranton as now defined or within the present limits of the Borough of Dunmore (except those of mining or railroad companies) of the value of $5000 or less caused by mine caves, we will bear the entire cost of repairing or restoring the same to as good condition as before. The commission shall be empowered to enfore this obligation.

Fourth, We will provide a fund of $100,000 in cash, Liberty Bonds or other trust securities, with a trust company or companies of the City of Scranton, the income and principal of which shall be expended on orders of the commission to compensate for damage or to pay for the repairs to existing buildings in Scranton and Dunmore as aforesaid, of the value of $5000 or less, in cases where they are damaged by mine caves and where the responsibility therefor cannot be determined, or where it rests with a company which has no successors and has gone out of business or become insolvent. (We must here except damage caused by the Delaware & Hudson Co. or its successors.) Where damage is caused by one of us it is severally and not jointly assumed. We will guarantee the maintenance of such fund to the amount of $100,000 for the entire period of 20 years from this date (July 8, 1918), so that such amount shall be intact at the expiration of 20 years to cover any damage thereafter incurred, or for such other proper purpose as the commission with the approval of the board may direct.

Fifth, Where there is danger of surface subsidence and of resulting damage to a structure exceeding $5000 in value and the owner thereof desires to obtain either artificial support or to purchase pillar coal for such support, and shall obtain the formal approval of the commission thereto, of the application wherefor we shall have notice and an opportunity to be heard before the commission, we agree to provide such artificial support as the commission may direct at the expense of the owner or to sell him such pillar coal as it may direct us so to do at a price to be fixed in each case by the commission which shall fully compensate us for the value of such pillar coal, the decision of the commission, however, on the question of value to be final. Pillar coal so purchased shall be granted to the owner by the coal company for the sole purpose of surface support with restrictions against the mining or removal thereof, and the coal companies shall not assume, because of any such sale of pillar coal, any legal obligations because of any surface damage or injury to persons which may subsequently ensue.

Sixth, This proposal applies to all cases where the right to surface support has been waived and to those only, and the obligation of each company subscribing hereto is several and not joint, and applies to its own mining operations only.

Seventh, At our first meeting your committee submitted to us a written statement with respect to the mine-cave problem which closed with this paragraph: "This committee believes that if there was in operation at this time a plan under which the surface owners were assured that every precaution would be taken to protect the surface where possible, or, if support is not feasible, that they be assured of receiving full damage for any injury that might result to their property because of the subsidence of the surface, then the fear and anxiety now existing should be removed."

We submit that the plan hereby proposed complies with your suggested solution to the extent of covering some 96 per cent. of the buildings of the surface owners of the city, and that with respect to the remaining 4 per cent. of such buildings it differs only in obligating the owner instead of our companies to bear the expense of their protection. If your committee will agree with us, as to the members of the commission and the form of the agreement between it and ourselves, we will immediately carry out this proposal.

This proposal was signed by the following companies: The Delaware, Lackawanna & Western Railroad Co., by W. H. Truesdale, president; Scranton Coal Co., by John B. Kerr, president; Pennsylvania Coal Co., by W. A. May, president; Peoples Coal Co., by Frank P. Christian, president; Green Ridge Coal Co., by W. L. Connell, president; Bulls Head Coal Co., by Jay Law, treasurer; Quinn Coal Co., by T. F. Quinn, treasurer; Spencer Coal Co., by David Spruks, president; Carney & Brown Coal Co., by John Carney, president; Nay Aug Coal Co., by David Boies, president.

Quite recently the directors of the Scranton Board of Trade met in secret session. It has been stated they ordered that the proposition just recited be received and filed, and earnestly recommended that this voluntary offer of the anthracite operators be given a fair trial. This expression of approval from the Board of Trade is significant, as it comes from a group of men representative of the best business and property interests of the city. There are many individual expressions of opinion in favor of acceptance and various members of the Board of Trade have made and are making speeches upholding the proposal. On the other hand, the Scranton Surface Protective Association has expressed disapproval of the proposal made by the operators.

The Mine-Cave Committee is still continuing its efforts to secure additional concessions and it is endeavoring to get the Delaware & Hudson Co. to sign the agreement. The fact that this important coal company withholds its signature to the instrument militates seriously against its meeting with general favor.

In this connection it is important to note that the coal operators in June, 1917, made an offer to repair all damages to structures valued up to $5000 in case they were injured by mining operations, also to repair streets and sell protecting pillars. The Delaware & Hudson Co. signed that offer for a five-year term, and it is understood that it is living up to that agreement.

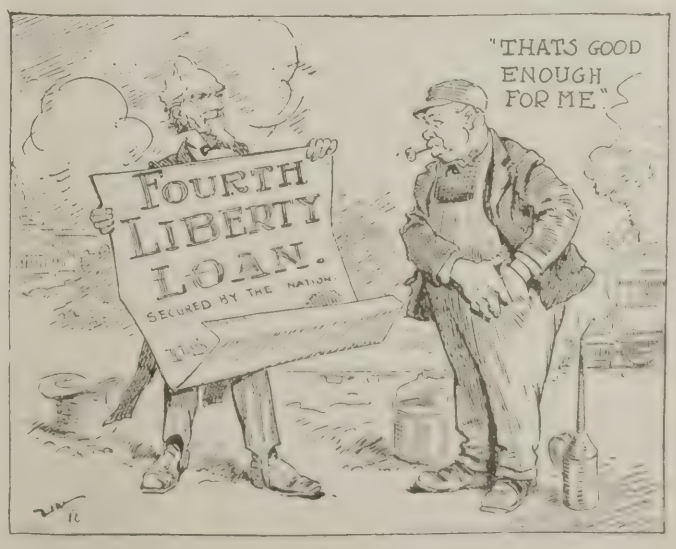
Since the proposal has been made public, popular sentiment has obtained two concessions which were not included in the original agreement: A proposal on the part of the coal companies to protect individual gas, water-service and sewer-pipe connections, and a modification of the terms of the proposal so as to provide for repairs to structures damaged from June, 1917, instead of from the time of the acceptance of the proposal as the provision now appears in that document. It is expected that the proposal now will come before the city council of Scranton, whose action is important, as the council is the legal agent of the people and the city.

An important feature of the present proposal is that it does not aim to give the coal companies any rights which they do not already enjoy, nor does it take away from the people any rights which they now possess. The proposal is a voluntary offer of the companies, who are willing to bind themselves to do certain things that present laws do not require them to do, and the people are not asked to sign any contracts. These concessions are conditional upon a reasonable attitude on the part of the people toward the proposal of the mining companies. The people will secure concessions simply by not resisting the proposal; if it is not accepted by acquiescence then the proposal is void. A strong opposition will put the matter back where it was and little will be gained.

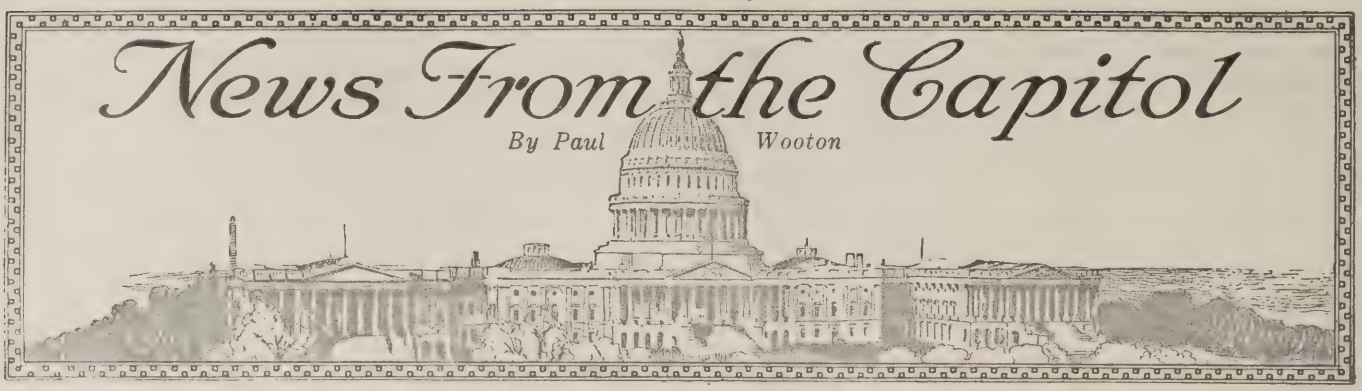
The coal companies agree that if at any future time a better proposition should be brought forward they will welcome it and substitute it for the one under discussion at present. On the other hand, the anthracite mining interests will fight any legislation supporting a proposition making larger demands on them. The parties to the controversy represent large investment demanding an opportunity for development. The mining companies own the coal and those controlling the surface have valuable property upon which to build. The coal interests do not wish to stop the real progress of the city, but they do wish to regulate it on commonsense lines. They do not care to be placed in a position where they will have to settle for damages to new structures, therefore they claim that those desiring to build should first secure a permit. There is sufficient safe ground on which to build. In the course of time, when a section is mined out and has settled, then it will be suitable for building purposes. Most of the city is over deep mining, and it is only in limited sections where the question would come up. Permits would tend to prevent construction in unsafe places. The matter should be so adjusted as to permit of the proper recovery of the coal and yet not to restrict the natural growth of the city.

Last year's developments have modified many views which were previously held by the users of fuel, particularly by the consumer of the domestic sizes. The present would seem to be the psychological moment to adjust differences connected with coal mining, at a time when the whole mining industry is being reviewed by the Government, costs analyzed and so on. Our dependence upon coal was never before brought out so strongly. We possess vast deposits of fuel, but they are by no means inexhaustible—the limited quantity of anthracite especially should be most carefully conserved at every point. The hard coal of Pennsylvania is a valuable asset, not only to the companies who control it but to the many millions of anthracite mine workers who find it a source of income, to the state which receives from it much assistance from taxes, and to the manufacturers which by its aid make various products. It is inconceivable that any step would be taken which would seriously handicap so important an industry.

Anthracite Shipments Continue To Increase



Anthracite operators and miners are keeping their promise to the United States Fuel Administration that the anthracite production of last year would be maintained and, if humanely possible, exceeded, as indicated by the statements of shipments reported to the Anthracite Bureau of Information. The shipments in August of this year have established a new record for that month, repeating a similar record made in July. The quantity sent to market last month amounted to 7,180,923 gross tons, an increase over July, when the shipments amounted to 7,084,775 tons, of 96,148 tons, and exceeding the tonnage of August, 1917, by 166,927 tons.



The total shipments for the first five months of the present coal year beginning Apr. 1, have amounted to 34,388,996 tons as compared with 33,297,109 tons for the corresponding period of last year, a gain of 1,091,887 tons, or a little over 3 per cent.

The shipments by companies were as follows:

	August, 1918	August, 1917	Coal Year, 1918	Coal Year, 1917
P. & R. Ry	1,408,501	1,373,473	6,764,594	6,316,774
L. V. R.R.	1,350,331	1,245,786	6,526,373	6,112,024
C. R.R. of N. J.	644,186	597,890	3,003,598	2,977,264
D., L. & W. R.R	1,048,346	1,118,986	5,143,966	5,241,109
D. & H. Co.	846,788	781,606	4,038,552	3,772,411
Penna. R.R.	504,367	504,819	2,433,488	2,447,163

L. & N. E. R.R.	360,922	392,643	1,706,496	1,729,230
Total	7,180,923	7,013,996	34,388,996	33,297,109

Good Security

Revision of Storage Regulations

The United States Fuel Administration announced on Sept. 14 a revision of the regulations governing the storage of coal by consumers listed on different preference schedules. This revision brings the practical distribution of coal into line with the statistics of production and consumption in different districts as developed during the past 30 days.

With the present complete information coming to the Distribution Division of the Fuel Administration and showing exactly the production, consumption and stocks on hand in every district, it is possible not only to change where necessary certain movements of coal, but the accumulation of winter storage, which is at this time the most important element of distribution, can be made to play an important part in getting maximum production or utilizing all available transportation most efficiently. Each week the Distribution Division has before it accurate figures showing the production of every mine during the week previous, also the consumption by all consumers and the accumulation of stocks on hand. If coal is taken into storage wherever possible in each district along the lines laid down by the regulations, it will militate to the advantage of both consumers and producers.

The amount of storage allotted to each district will be altered from time to time as may be necessary to carry out the plans of the Distribution Division for the coming winter. This plan is designed to obtain the utmost from our transportation equipment with the least danger of any district being out of. coal next winter on account of its distance from the mines. Consumers on the preference classes recently defined by the War Industries Board are permitted to accumulate reserve stocks of bituminous coals as follows:

Maine, 135 days; Massachusetts, Vermont, New Hampshire, northern New York, 105 days; Connecticut, Rhode Island, southwestern New York, 90 days; southeastern New York and New Jersey, 60 days; Delaware, eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and western Ohio, 45 days; western Pennsylvania, West Virginia, eastern Kentucky, eastern Ohio, 35 days; lower Michigan, 90 days.

Consumers in class 2 are permitted to accumulate reserve stocks of bituminous coals as follows:

Maine, 120 days; Massachusetts, Vermont, New Hampshire, northern New York, 90 days; Connecticut, Rhode Island, southwestern New York, 75 days; southeastern New York and New Jersey, 50 days; Delaware, eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida, western Ohio, 40 days; western Pennsylvania, West Virginia, eastern Kentucky and eastern Ohio, 30 days; lower Michigan, 75 days.

Consumers in class 3 are permitted to accumulate reserve stocks of bituminous coals as follows:

Maine, 105 days; Massachusetts, Vermont, New Hampshire, northern New York, 75 days; Connecticut, Rhode Island, southwestern New York, 60 days; southeastern New York and New Jersey, 40 days; Delaware, eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida, western Ohio, 35 days; western Pennsylvania, West Virginia, eastern Kentucky and eastern Ohio, 25 days; lower Michigan, 60 days.

Consumers in class 4 are permitted to accumulate reserve stock of bituminous coals as follows:

Maine, 90 days; Massachusetts, Vermont, New Hampshire and northern New York, 60 days; Connecticut, Rhode Island, southwestern New York, 45 days; southeastern New York and New Jersey, 30 days; Delaware, eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and western Ohio, 30 days; western Pennsylvania, West Virginia, eastern Kentucky and eastern Ohio, 20 days; lower Michigan, 45 days.

Consumers not on the preference list are limited to the following stocks:

Maine, 45 days; Massachusetts, Vermont, New Hampshire and northern New York, 30 days; Connecticut, Rhode Island, southwestern New York, 20 days; southeastern New York and New Jersey, 20 days; Delaware, eastern Pennsylvania, Maryland, District of Columbia, Virginia, Florida and western Ohio, 15 days; western Pennsylvania, West Virginia, eastern Kentucky and eastern Ohio, 15 days.

There is no restriction on the stocks of screenings which may be accumulated by either preference or non-preference consumers in Ohio or Lower Michigan, nor is there any restriction on the stocks of Indiana, Illinois or western coal which consumers may obtain.

Supervision of the accumulation of stocks in accordance with these limits will be exercised by the several State Fuel Administrators who are authorized to make exceptions where special conditions make it necessary.

Keeping Tabs on Absentees

Under a modification of the Fuel Administration's production committee plan, the Clearfield Bituminous Coal Corporation, operating eight collieries, has attained gratifying results. H. J. Hinterleitner, general superintendent, with headquarters in Clearfield, Penn., says that a marked advance has been made in the average daily tonnage per miner employed and that absence from work has been reduced from 21 per cent. to 9 per cent. within three months.

It was in May that the foremen and superintendents of the company met to discuss production, and it was decided finally to have a committee at each mine, to be comprised of three miners in addition to the foreman and his assistants. The locals of the United Mine

Workers took an interest and assisted the foremen to choose representative miners, men of sound patriotism. Foreign-born citizens are included in these committees.

Through their work, these committees reduced the percentage of absence from 21 in May to 13 in June, and in July there was a general meeting of all the committees in the Clearfield office. Charles O'Neill, production manager for the district, and other prominent mining men attended. It was finally decided, among other things, that each absentee from work should be visited and invited to tell why he was absent. This phase of the work is not running so smoothly as it might just yet, but a good start has been made, according to M. D. Edmonds, of the Fuel Administration, who just has visited the section.

In August the total number of working days lost at the company's mines was 2379. The committees were able to report on 1620 of these lost days. Some of the reasons would be humorous, Mr. Edmonds says, if absenteeism at the mines were not such a serious matter. Liquor was responsible for 93 of the lost days. Soreness of arm, hand, leg, knee, foot or back accounted for 107. Sickness or other disability was responsible for 485 lost days. Mr. Edmonds believes that some of the ill health was chargeable immediately or remotely to liquor. Thirteen of the lost days were due to the fact that the man who should have been working was motoring instead. Ninety-seven days were lost because the miner was doing farm work. In 36 instances the miner failed to arrive in time to go to work. Nine gentlemen "did not feel like working," while 38 gave no excuse. Injuries and other reasons, most of them legitimate, accounted for the rest of the delinquency.

Suggested Changes in Revenue Bill to Benefit Coal Production

Changes in the revenue bill, which will improve the coal situation, were pointed out to the Senate Finance Committee by J. H. Allport. Mr. Allport appeared in behalf of bituminous coal operators. He was introduced to the committee by Senator Penrose of Pennsylvania. A portion of Mr. Allport's statement is as follows:

We find in reports of the probable wording of the new War Revenue Bill and in the rulings of the Treasury Department a strong tendency to put costs of certain necessary mine work usually paid out of earnings to capital account and thus increase the taxable earnings.

This, we believe, is resulting in a curtailment of improvements and developments in the coal mines which will inevitably result not only in checking increases in production, but in an actual and very serious decrease in the present production.

The operators cannot and dare not increase their capital by charging to capital account developments and replacements necessary to maintain production, nor can they thus charge the full cost of extensions and new machinery necessary for increased production and to replace man power by machinery at the present abnormal costs, as they well know that under normal conditions they will be unable to earn the interest charges on such inflated capital.

Under these conditions we would respectfully suggest that influence should be exerted to avoid such a catastrophe and we would urge that the utmost efforts be exerted to have included in the pending war revenue bill the following principles:

In all coal mines operating expenses to be deducted from gross earnings shall include all expenditures made during the tax year for:

1. All extensions required to maintain output, including the cost of all labor, materials, machinery, and supplies.
2. All machinery installed to replace human labor, including the cost of installation.
3. The cost, above pre-war figures, of all improvements and developments made to increase output, including all labor, machinery, material and supplies required for same. The cost of such improvements at pre-war figures to be charged to capital account.
4. An allowance for "mining hazards," if actually set aside in cash or invested in Liberty Bonds, of not exceeding 2½ per cent. of the value of the coal at the mines.

We believe that if the above can be included in the War Revenue Bill, the result will be to permit and encourage substantial increases of output, which under the law as now proposed and as interpreted by the Treasury Department, would not and could not be attained, and we believe unless action of this sort is taken that instead of the necessary increase an actual and probably serious decrease of production will result.

Further, with such a law the taxable income of the mines will, we believe, yield a far greater revenue to the Government than will be yielded if development and extension is penalized by putting these charges into capital.

Government to Operate Barge Line

Operation of the Government's barge line on the Warrior River in Alabama is to begin in the near future. A considerable number of barges have been secured by the Government, including several self-propelled steel barges. This equipment is capable of taking coal to tidewater at New Orleans at the rate of 300,000 tons annually. Marine designers, however, are at work on new steel barges especially designed to obtain the full efficiency of the Warrior River's locks. When these barges are in service, they will have a combined annual capacity of 1,600,000 tons of coal. The Railroad Administration has leased the Lake Borgne Canal, which allows the landing of coal at the locks in the Mississippi River at Violet, just below New Orleans.

Ordnance Department Officials Transferred

Twenty-two officers and civilians formerly handling fuel matters for the Ordnance Department and located in various production districts have been transferred to the Quartermaster Corps and have been assigned, under the direction of the Fuel and Forage Division of the Corps, to the offices of the State Fuel Administrators in New England and the states east of the Mississippi River, the War Department announces.

The location of these representatives of the Fuel Branch follows out the decentralization plan of the Fuel Administration, and while they will be located in the State Fuel Administrators' offices, their duties will be to assist all War Department contractors in securing their fuel requirements. They will also be of service generally to all coal consumers who are supplying equipment or material to the War Department.

A weekly meeting of the representatives of the various corps or bureaus of the War Department is held in the Fuel Branch of the Fuel and Forage Division of the Quartermaster Corps, at which are discussed all matters pertaining in any way to fuel assistance to army contractors.

Coking Coal Production Records Broken

Coal production in the Connellsville district of Pennsylvania continues to break all records. Reports forwarded to James B. Neale, Director of Production, United States Fuel Administration, by W. L. Byers, Production Manager, say that in the week ended Sept. 14 the output was 736,621 tons, a gain of 18,400 tons over the previous high record.

This continued increase in Connellsville coal is of direct importance to the military agencies responsible for supplying shells and guns to the American army in France. Connellsville coal is a high-grade fuel from which is derived much of the coke used in making steel for military use.

The increase of last week, 18,400 tons, if reduced to coke, would be sufficient to manufacture approximately 10,000 tons of pig iron to be converted into shell steel, gun forgings or plates for ships. It is the expectation of the local production committees to bring the weekly output of the Connellsville district up to 800,000 tons.

Production Committee Plan Successful

The production committee system, sometimes in modified form, is in force at mines representing 85 per cent. of the output in central Pennsylvania, according to Charles O'Neil, production manager for the Fuel Administration. Already a group of mines which embraces the Rochester and Pittsburgh Coal and Iron Co., the Jefferson and Clearfield Coal and Iron Co., the Tidewater Coal Co. and a few others is reported to be expecting an increase of a million tons during this coal year, or roughly 20 per cent. increase, through the work of production committees. The Allegheny River Mining Co. is finding the plan successful, and at the Seminole mine the committee has reduced the Monday idleness percentage from 26 per cent. to 7½ per cent.

United States Coal Exports in July

An increase is shown by official statistics in the amount of coal exported in July of this year, as compared with July of last year. Figures compiled by the Department of Commerce for July, 1918, and those for July, 1917, as finally revised, are as follows:

Exports	July, 1917	July, 1918
Anthracite, tons	390,619	395,537
Bituminous, tons	1,567,461	2,244,530
Exported to:		
Italy	28,522	.....
Canada	1,389,261	1,873,750
Panama	23,849	55,656
Mexico	5,334	11,536
Cuba	51,193	105,137
Other West Indies	25,805	19,437
Argentina	12,743	47,528
Brazil	12,122	68,362
Chile	.....	1,343
Uruguay	2,755	49,685
Other countries	17,883	12,095
Coke, tons	52,665	145,490

The only coal imported into the United States during the month under review was from Canada. The amount brought in during July of this year was 108,656 tons, which is 400 tons more than the imports for the same month last year.

American imports were $241,000,000 in July, compared with $260,000,000 in June. For the first seven months of 1918 the imports were $1,767,000,000, as against $1,779,000 last year.

Legal Department

United States Coal Land Entries.—Under Federal statutes authorizing entries upon coal lands of the United States, but declaring that the statutes "shall be held to authorize only one entry by the same person or association of persons," a corporation, although entitled to take up 320 acres under a single entry, exhausted its right in the taking up of a tract of 84.4 acres by an individual for its benefit, and could not acquire valid title under subsequent entries made for its benefit. (United States Circuit Court of Appeals, Eighth Circuit; Union Coal and Coke Co. vs. United States; 247 Federal Reporter, 106.)

Accident at Coal Conveyor.—Plaintiff, a laborer, was assigned to the task of removing rock, wood, etc., from a moving coal conveyor. The traveling wheels on which the conveyor belt ran were secured on their axles by bent nails used as a substitute for cotter pins. One of these nails caught in plaintiff's clothing, resulting in his serious injury. Held that the employing company is liable as for violating the Alabama Employers' Liability Act by permitting the existence of a defect in the condition of its ways, works and machinery, or on the theory that the foreman was negligent in assigning plaintiff to work in a dangerous place. (United States Circuit Court of Appeals, Fifth Circuit; Russell vs. Sloss-Sheffield Steel and Iron Co.; 247 Federal Reporter, 289.)

Explosion of Mine Gas.—If plaintiff, a miner in defendant's employment, was injured through an explosion of mine gases accumulated where he was working at the face of an air-course, driving the course and mining coal therefrom, and if the accident was due to the operator's failure to furnish a sufficient current of fresh air to the face of the course for the purpose of diluting and rendering harmless any noxious and explosive gases that might be accumulated there, plaintiff is entitled to recover damages, unless the accident can be attributed directly to some negligent act on plaintiff's part or to his so suddenly opening the gases in the course of his work that, in the ordinary and customary methods of inspection, the dangerous condition was not discovered or discoverable by the operator before the occurrence of the accident. (Oklahoma Supreme Court, Tolekis vs. Rock Island Coal Mining Co., 171 Pacific Reporter, 17.)

Liberty Bonds Keep Both Running

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Only with difficulty can one speak with composure about the strike in the area of the anthracite region lying between Shenandoah and Shamokin. Many of the mine workers themselves acknowledge that the action of their fellows was inexcusable. It is solely because of the generality of that opinion among the men that the mines are once more again at work. It is, however, hard to have to admit that in the coal industry there are so many disloyal men that a strike of the magnitude of that which occurred could be put into operation.

Let us resolutely turn our attention to the brighter side of the picture, remembering that the workingmen of America are so numerous that they truly constitute this nation. To doubt the essential rightness of their impulses is to question the essential rightness of the American people. It is treason to believe, as some of us do, that the heart of the workingman is not right.

NATION IS NO GREATER THAN ITS WORKINGMEN

We who believe that America is a shining exemplar among forward-looking nations must change our notion if we cannot on the whole indorse our working class. Labor must be regarded as loyal and patriotic, or we must despair of our nation. Under a democratic government a nation is no greater than its electorate, and its electorate being dominated by its laboring element is not greater than its workingmen.

There is no reason to believe that our laboring men are not animated by the purest of Americanism. The strength with which labor threw aside the Bolshevism of the leaders in this strike tends to prove this thesis. The nation must rest on its workingmen, and America can well afford to do so. The majority of them are sane, clean, sacrificing fellows to whom an opportunity for service is always a call of duty.

Because of this attitude the strike did not spread to the Wyoming-Lackawanna and Lehigh regions. At Hazleton there was no talk of trouble. The district officers of the United Mine Workers in District No. 7 met at Nesquehoning on Sept. 16 and passed a resolution condemning the unauthorized strike in District No. 9.

ANTHRACITE STRIKERS ARE MOSTLY FOREIGNERS

It is said that 80 per cent. of the strikers are foreigners and that a large number are of Austrian birth or of Austrian ancestry. The English-speaking miners are for the most part opposing the strike. As for the new union of petty officials, nobody expects any trouble from that source. They are recognized as "members of the official family," as Robert A. Quinn, the general manager of the Susquehanna Collieries Co., well says, and the companies are disposed to look upon their action with kindly consideration. They know these men are working harder and making less money than the miners under them. The operators contend and contend rightly, that before the war the work of the foremen was steady, whereas the mine workers received only part time. But the divergence in pay cannot be satisfactorily explained on that basis alone. There will never be any degree of difficulty between these bosses and the operating companies, for the common viewpoint of employer and employee makes a strike unnecessary and unlikely.

Although coal is an essential in the nation's warfare, commissary and mine clerks are not to be granted deferred classification. This fact has led some people to regard these workers as performing an entirely nonessential service. That is, of course, ridiculous. The orders of Provost Marshal General Crowder class these men as easily replaceable, though essential. When the draft fails naturally upon them they are subject to it, but unless it does, they cannot be required to enlist or leave their present service. They are working acceptably to the nation and the "work or fight" order does not apply to them. That order, however, is said to apply to sales agencies and sales companies.

In the Connellsville region the system of keeping track of the slacker recently put into operation is working well according to statements made at a recent meeting between Walter S. Blauvelt, coke director of the United States Fuel Administration, and the operators of the Connellsville region. The men are now working more steadily.

So far, for the most part, the companies have posted the names of those only who, without reasonable excuse, miss a day's shift. But they are now beginning to list the full-time men on the bulletin board, and at some mines a small button is issued to loyal mine workers. Production Manager W. L. Byers has been so much impressed with the value of posting records of full-time men that he has ordered the plan to be followed at all mines, the names being posted every two weeks.

EVERYONE MUST WORK FULL TIME OR FIGHT

It is quite likely that we shall soon write Provost Marshal General Crowder's famous dictum, "Work or fight," in a more wordy but more definite way: "Work full time or fight." W. L. Byers, the production manager just mentioned, and George E. Gay, a member of the appellate draft board, have decided that consideration shall only be given to full-time men when applications are made for deferred classification. Men who lapse will have no standing with the draft board and the production department will regretfully have to stand by when their enrollment is considered. Only a diligent mine worker will get credit for his win-the-war activities.

There are three bituminous regions which the United States Fuel Administration is particularly anxious to spur into activity. Naming them in order they would probably run: West Virginia, central Pennsylvania and western Pennsylvania. The first two produce the highest grades of coal for bunker, byproduct and smithing uses and the third furnishes a large production of the beehive coke. Being so near Pittsburgh, the output of the western Pennsylvania coal has from that fact alone an unusual importance.

NEALE GIVES GOOD COUNSEL TO MINE OPERATORS

A meeting was held at White Sulphur Springs, W. Va., on Sunday, Sept. 15, under the auspices of James B. Neale, the director of production of the United States Fuel Administration. More than 200 operators, managers and general superintendents, and prominent railroad men were present. Important heads of the Fuel Administration were also there to give counsel.

Mr. Neale appealed to the presidents of the companies and to all the other officials to get "to the pit just as often as possible." "Don't deceive yourself," he added, "with the idea that the office at New York, Philadelphia, or Boston demands your attention. Be shoulder to shoulder with the boys getting out the coal. Don't sit back on Broadway and write to them to "Go to it," but go down to the mine and urge them to "Come to it."

He then observed that the operators, like the mine workers, were obsessed with the idea that the interest in the

war lay in France. He impressed on them that an extremely vital part in the war was the work they were doing.

"You are not going to be in the spotlight," he said, "but I wish to emphasize for you the courage of the commonplace." Speaking of the lack of coöperation between the mine workers and their managers and employers, he said to the latter: "If your miners are not in sympathy with you, it is not wholly their fault. The time to change the attitude of the miners in your favor is now. I call upon all operators to do what is noble and fine. There is not a man in this room who does not accept the idea of the brotherhood of man as a theory. I want him to accept it as a fact. If this is a war of righteousness, we should be righteous here at home and do here those things we ought to do."

Neale Appeals for Greater Breadth of View

Mr. Neale referred also to the tendency of the operating heads to bewail the draft and the car supply instead of busying themselves to find out what they could themselves do to remedy the conditions by which they are faced. He urged the operators to put their stress on the righteousness of the cause rather than on the opportunity to make money, believing that the miner would be far more swayed by patriotism than by pelf. Speaking of production committees, he said: "Let us recognize that this is a big job and that the work to which we have set our hand cannot be done by little men—I don't refer to stature. Do nothing that betokens spite, envy or jealousy. Handled rightly, the committees will do important service. When the blame is found to lie with the bosses, let the bosses accept it as a fault of the company. If the company tries to pass the buck to the men or vice-versa, production committees will prove to be a farce." Mr. Neale said that the material support given to the boys in front would save their lives and he urged that between materials and lives there could be but one choice.

A letter from President Wilson to Adam B. Littlepage of the House of Representatives was read. It runs as follows: "I am sure that I am only one of thousands of Americans who have been proud of the fine spirit manifested by the operators and miners of West Virginia. West Virginia, as we all know, supplies the coal that must be used to run our battleships and destroyers and to enable us to transport our soldiers across the sea. The coal miners and operators of West Virginia, therefore, are playing a very direct and responsible part in the conduct of the war. Will you not take occasion to express to them the very high appreciation of the Government and its confidence in the continuance of their zealous and self-sacrificing efforts?"

The district draft board for the southern district of West Virginia has classified coal-mine workers, who are properly proven experienced and efficient, as "skilled laborers" in a "necessary industy" and has decided to classify them in Class 2-D. This ruling is applicable to the future only and does not in any way affect miners heretofore classified without deferment and who have been inducted into military service.

Consolidation Resolute for Wage Contract

The recent agreement with the union in the Fairmont region terminates a long period of cross purposes. The Consolidation Coal Co. was induced to accept the policy of the War Labor Board in favor of allowing union labor organizations to follow out their "legitimate activities." This decision, announced by the *Wheeling Majority*, a labor paper published in Wheeling, W. Va., was denied by a Fairmont paper on the authority of a leading official of the "Consolidation," but it ultimately proved to be true, for later George T. Watson himself came to Fairmont and broke the news.

The coal operators' association did not approve of this free-lance action of the Consolidation Coal Co., feeling that any such momentous decision should have been considered in conclave. But as this, the major company of the region, almost welcomed the labor organizers, nothing could be done to keep them out. While the organizers were building up a strong union membership, the Northern West Virginia Coal Operators' Association was expanded by the absorption of four minor organizations. When the association thus strengthened met at Clarksburg they were fully determined to give the mine workers no recognition.

Again the Consolidation Coal Co. acted independently, but when George F. Watson came to Fairmont and again put the matter before leading operators there was not a single one who heard his talk and held out. So a group of operators representing 87 per cent. of the production of the region met the scale committee of the miners and signed an agreement. In the latter part of last week Frank Keeney, president of District No. 17, with his scale committee, met the Sewickley vein coal operators at the Fairmont Hotel, Fairmont, W. Va., and they signed an agreement. In both agreements—that with members of the Northern West Virginia Coal Operators' Association and that with the Sewickley Vein Coal Operators' Association—the Flemington scale was accepted. Flemington is in the Fairmont district and it gives its name to a section which was unionized some time before the United States took any hand in the present war.

No Man's Wage To Be Lowered by Agreement

Some mines are paying more than the Flemington scale. The wages which are paid to the men in the employ of these companies will be regarded as a right of which they are not to be deprived so long as they remain in the employ of that company. When a new man is employed the rate of pay will be reduced to that provided in the Flemington wage scale.

More than 200 striking miners at the Devereaux mines near Springfield, Ill., have returned to work as the result of a conference at the office of United States District Attorney Knotts. The men had been idle about three weeks and production was curtailed 1000 to 1200 tons a day. Some time ago the company at the request of the miners' local substituted one make of powder for another. The miners after a short trial complained that the new powder did not work as well as the old, and submitted the question of discontinuing it to a commission composed of the district board members, Steve Sullivan and Dan Clark, representing the operators' association, which decided against the miners. The miners refused to comply with the finding and quit work. At the request of both parties the controversy was referred to the district attorney. Several conferences were held. At the final one the miners agreed to return to work pending an investigation as to the merits of the powder.

Local Wants Operator To Pay for Men's Bonds

In the Belleville district of Illinois one of the local unions has passed resolutions urging its district and national officials to do all possible to secure an increase in wages so that the miners may be enabled to subscribe for Liberty Bonds. The local (No. 99) passed the following resolution: "Whereas, an increase in price of coal has been granted the coal operator within the past year, thereby allowing him to exact enormous profits over and above the price at present paid for mining and whereas the Fourth Liberty Loan drive is fast approaching and may well place the coal miner in a bad light by reason of his inability to purchase bonds comparable in amount with those purchased by the coal operator with money which we deem rightfully belongs to the miner who produces the coal, therefore be it resolved that we, the members of Local 99, go on record as favoring a just and substantial increase in wages and urge upon the district and national officers to employ every effort toward securing it." The union voted to make an assessment of $1 per member for five pays, the money thus collected to be disbursed as donations to patriotic organizations.

All the 200 miners employed at the Groveland mine of the Groveland Coal Mining Co., Peoria, Ill., have returned to work, the trouble which brought about their strike being satisfactorily settled. The men refused to work when the company would not or did not install a heater to dry their clothes. The heater has been set in place and the men have returned to work. The Lake Erie mine was also idle because of a disagreement over the wage paid.

Anthracite Miners Strike and Resume

After much agitation several mines in the anthracite region finally went on strike, Sept. 16. Prior to that time there had been many suspensions, as will be seen by a perusal of last week's summary, but on the date just mentioned the disorder broke out in many more places and covered a new and larger area. The many mines located at Shamokin, Ashland and Shenandoah were involved, but strange to say Mt. Carmel, lying between the first two cities, and Mahanoy City, which is quite close to Shenandoah, was not affected.

Broad Mountain also, which shuts off the field just mentioned from the Lykens Valley, Tremont, Minersville and Schuylkill Valley operations, acted as a fire wall to prevent the strike from spreading southward, though at one point south of Broad Mountain a strike did occur, namely at the Lykens operation of the Susquehanna Collieries Co. In all about 25,000 men went on strike, and the output of the anthracite region was cut about 5 per cent.

It must not be thought that at the mines which suspended there was any unanimity in favor of the suspension. It was evident that a number of men were kept away from work by intimidation. The union was against the strike, but the radicals who favored a suspension and who were said to be Industrial Workers of the World picketed the plants and made all opposition to their plans dangerous and inadvisable.

Americans Do Not Believe in This Strike

Where men are ardently volunteering for war one will not fail to find a large number who believe that their duty lies in supporting those who have gone to the front, and it was so in the strike region. At Mahanoy Plane, Local Union No. 1542 expressed itself as wanting "the world to know that its membership is composed of good stanch American citizens who propose to stand by President Wilson and the international union officials until the wage question is adjusted in a business-like manner. This union will take no part in the walkout and the members will continue to work like true Americans in order that the war may be brought to an early and successful consummation."

In the village of Frackville, a short distance from Shenandoah, where John McGinnis and other citizens had organized a Home Defense League, the pickets were ordered to go home or go to work, pending the Government's decision, and the threat was made that if they failed to accept one of these two most wholesome alternatives they would be interned as enemy aliens.

Dr. H. A. Garfield, the United States Fuel Administrator, telegraphed James Matthews, the president of the district (No. 9), as follows: "Please make it perfectly clear to all your men that as long as they are out on strike I will not confer with them, nor take any steps in their behalf and that they will be held personally and strictly responsible."

Voices Are Raised Against the Strike

This was Sept. 16. The next day saw a big change. District No. 7 on that day decided that its 20,000 men would continue at work. The St. Clair district voted similarly, blocking the strike to the south. Reports from Shenandoah, Girardville and Ashland showed that the men were going back to the mines. A few bad men were not able to keep them away from work after once the clergy and the business men had had an opportunity to argue the matter with them and a chance to urge on them immediate resumption.

The men at two of the Madeira-Hill & Co. collieries voted to go back to work, and so also did the mine workers of the Reading Coal and Iron Co. except those at Shamokin. Several mines at Lykens were, however, by this time involved and the men at these refused to resume their labors. Shamokin proved more obdurate than the other regions because of the campaigning of Chris Golden, who is a candidate to succeed James Matthews as district president. His influence is largely local, and Ashland, Shenandoah, Mahanoy City, St. Clair, Tremont and neighboring towns were not nearly so disposed as Shamokin to follow Golden and discredit Matthews.

A convention on Sept. 18 at Shamokin ended the strike. This conference was called by independent strike leaders without the approval of the United Mine Workers of America, a body which in no way countenances the abstention from work or any activity in connection therewith. As a result of this vote, on Sept. 19, the strike practically came to an end. On that date only the Blackwood colliery of the Lehigh Valley Coal Co. and the Buck Run colliery of the Buck Run Coal Co., at Minersville, remained on strike but the resumption of both collieries was expected on the morrow.

The mine workers complain principally about the higher wages paid in the bituminous field, where large increases have been given to correct the irregularity in the running of the mines. Now, however, the bituminous mines run almost as regularly as the anthracite. Another complaint of the anthracite men is that the cost of living is rising. They also claim that wages are higher in other war industries, which are not in any way more necessary nor more hazardous. To cap the climax they allege that they have been importuned to buy Liberty Bonds and War Saving Stamps and to give money to the Red Cross. They believe that they should not give this money themselves. The companies should pay them more wages and thus give them the means to subscribe without sacrifice to these worthy objects.

Some Demand Money To Pay for Bonds

If the money must be given them to "put in the plate," it is idle to pass the plate to them. Let it be handed to those who are willing to give of their own. The public cannot afford to pay the coal miners for Liberty Bonds purchased as well as for services rendered. The public would sooner pay present prices for coal and buy Liberty Bonds itself. If Liberty Bond money is to be presented to the miner, then he is making no sacrifice in the buying of bonds, and he is rendering no service to the nation in purchasing them. Probably there are but few of the mine workers who harbor the foolish idea that bond purchases entitle the purchaser to a wage increase, though, of course, a man who has subscribed heavily would find such an increase more than convenient.

In the northern anthracite field the situation is quite tense though the strikes have been only local. There is a general movement for a strike and a new union. It is, however, general in this sense only that it is found at most mining centers, the degree of its strength in some places is possibly open to question. Most of the men oppose the strike and many are still loyal to the union. On Sept. 14 the Langcliffe mine workers of the Hudson Coal Co., in Avoca, who are mostly Austrians, voted to continue their strike till an increase of wages is granted. These men demand $7 a day for miners and $5.50 a day for all other workers about the collieries.

Langcliffe Miners' Demands Preposterous

These demands are preposterous. The wage earners in other industries who have received no increases in wage whatever since war began feel bitterly about miners like those of the Langcliffe type, who are putting both feet into the feeding trough and are absorbing everything for themselves while good American workingmen go without. The public will have to pay for the Langcliffe profiteering, and they are getting impatient. The American people are beginning to feel that it is time to cry "America for the Americans" and tell these foreigners that this country is not a place for their exploitations.

We are a long suffering people and have a warm place for the foreigners whose hearts and aims are in common with ours and who are willing to fare equally with us as citizens of a common country. But these rascals who strike while Americans work, who demand that they get twice as much as the generality of unskilled Americans, are arousing in America a spirit which they will keenly regret.

EDITORIALS

Miners Oppose Ending of Apprenticeship

MINERS in the anthracite region are strongly wrought up about the attacks now being made on the long-established apprenticeship requirement in the mining law of the hard-coal region. No man can act as a miner until he has had two years of experience. The miners say that if the law were repealed it would not aid in increasing production, for the shortage of men is greater in the ranks of the laborers, motor runners and drivers than in the ranks of certificated miners. They urge that if the employments now open to all comers cannot be recruited, what chance is there that the indiscriminate opening of other employments would cause those employments to be adequately filled with men?

The following table shows the facts as published by the anthracite operators. It will be seen that, at least in April, the shortage of miners was greater than the shortage of day men, but that condition was in some places reversed.

Employments	Men Employed, 1918	Men Employed, Apr. 1, 1918	Increase or Decrease	Per Cent.
Miners	42,830	42,186	—644	—1.504
Miner's laborers	21,990	20,768	—1,222	—5.557
Company men (inside)	42,763	42,143	—620	—1.450
Company men (outside)	42,949	42,515	—434	—1.011
All other employments at collieries	5,448	5,480	+32	+0.587
Total	155,980	153,092	—2,888	—1.8515

The table statistically supports the contention of the miners. The laborers from whom the supply of miners is to be replenished have decreased in numbers 5.557 per cent., whereas the loss in the number of miners has been only 1.504 per cent., or roughly a fourth as great.

But statistics occasionally form an unsatisfactory ground for an argument of this kind. The reason why mine laborers leave is because they are only mine laborers. They have the irksomeness of being tied down to a miner, who does little of the work and walks off with the bulk of the pay. The figures show that mining as compared with mine laboring is a desirable occupation, and that if it were thrown open to everybody it would prevent a number of men from leaving the industry and might well be the cause of a number entering the ranks.

The exodus of mine laborers results from a natural rebellion against the unfair conditions existing. Put the new man on a fairer footing, and it is quite likely that the ranks will be recruited. Where all employments are free and open there is a chance that they will be filled. Where privilege closes an employment it does not follow that it would not be filled if the privilege were removed. That men do not crowd to be underlings and to get poor pay is not a new phenomenon. So it is not strange, but natural, that the ranks of the mine laborers are the worst filled of any.

If the present conditions continue there may come a time when there will be no mine laborers whatever. It will mark a period of emancipation and democracy, and not at all a time to be regretted. In the soft-coal mines there is no distinction. All coal diggers are "buddies" with equal shares in the tonnage produced. There is no talk of "man and superman," and under this arrangement working forces of miners steadily increased till the war commenced. Even in 1917 the number of mine workers in central Pennsylvania was 7.5 per cent. greater in 1916.

A Corporal in Every Squad of Eight

IN THE army it is necessary so to arrange authority that every man is in touch with the commander-in-chief and can be set in movement by him. To such an extent is this carried that, as everyone knows, there is a corporal over every seven men.

We need an equal extension of authority in the mines. We do not want our men "bossed to death," but we want the coöperation and assistance which invariably result from the delegation of authority to an adequate number of men, and we want the complete knowledge which can only be attained by a sufficient extension of authority.

It is true that the appointment of an assistant foreman is often a misfortune. It furnishes a jealous foreman a chance to quarrel. It supplies an ambitious underling with an opportunity to strut in the limelight. It gives occasion to the assistant to put a burdensome yoke on the neck of the worker.

But while this may be the unfortunate result, it does not by any means necessarily follow, and the introduction of many subforemen instead of only one tends to have a totally different effect. The appointment of more numerous subordinates menaces the foreman's standing with the company less than the employment of one. When there are many of them there is less likelihood that the subforemen will overestimate their "brief authority." Appointed with the right kind of a talk, their appointment cannot fail to do good. They are there to help—to help the company, the mine foreman and the miners. They are to build up tonnage, to aid in securing clean coal, to increase enthusiasm, to represent the good will of the company, to coördinate the work of the various company employees, to learn just where the productive energy has or is about to be wasted or to be found lacking. They are not so much to rule as to aid. Good nature is as much needed as authority; leadership is required rather than drivership.

The companies with the biggest tonnages per man and the best handled mines are those with plenty of face bosses. The United States Coal and Coke Co. favors one sub-boss to 25 men. The Ellsworth Collieries Co. has always employed many subforemen. The Pennsylvania Coal and Coke Co. has just given its adhesion to a policy of one boss to 25 men and has appointed several "scouts" whose business it is to find why tonnage is not maintained. The Delaware, Lackawanna

& Western R.R., Coal Department, has had a number of men employed in just this capacity.

But it is a question whether that is really enough. The corporal is a fighter with his men. There is no reason why we should not have corporals in the mines who will work as well as lead the men. A man who can talk some foreign language could be corporal to those of the same nationality and could explain to them the conditions under which work is being, and should be, performed. He can explain why men are idle, why their tonnage is low, why their coal is not clean, why men are injured, and he can exhort them and the company to correct all the deficiencies whereby the tonnage is kept low, the coal is sent out dirty and men are converted into casualties.

The mine foreman cannot do all that is expected of him, but unfortunately he does not like to delegate authority. He will complain volubly about his inability to fill the myriad of activities demanded of him, but he is nevertheless opposed to dividing his responsibility. He is always on edge with the constant worry of his job, but just the same he wants to muddle along with it unaided. He knows he is performing it badly because one man cannot perform such a job well. When he is underground, he wishes he were at the tipple; when he is at the tipple, he wishes he were underground.

For the most part, he is in his little doghole of an office, scolding the miners for venturing to tell him that their places need rails or dewatering or a switch or air or props or something. He cannot correct these faults, for he lacks the subordinates to prove up the facts as stated or to put the necessary remedies in operation, and too often he lacks even the telephones to transmit his orders. If he goes underground, a quarter or a half a day is lost, and in the meantime he may be needed more outside. The superintendent will be storming because he cannot find him. So he finds it more profitable to swear at the miner and tell him to take his tools out if he doesn't like the place, all because he is not rightly equipped with help. So much for the present condition. Now for a statement of how it should be.

He should never even see that miner. The subordinate inside should have seen him and attended to his difficulty or should have corrected the trouble before the miner had time to complain of it; but in any event it should have been corrected by the subordinate before the miner made a two-mile trip to complain, only to meet with a rebuff from the foreman or to find a long queue of complainants ahead of him.

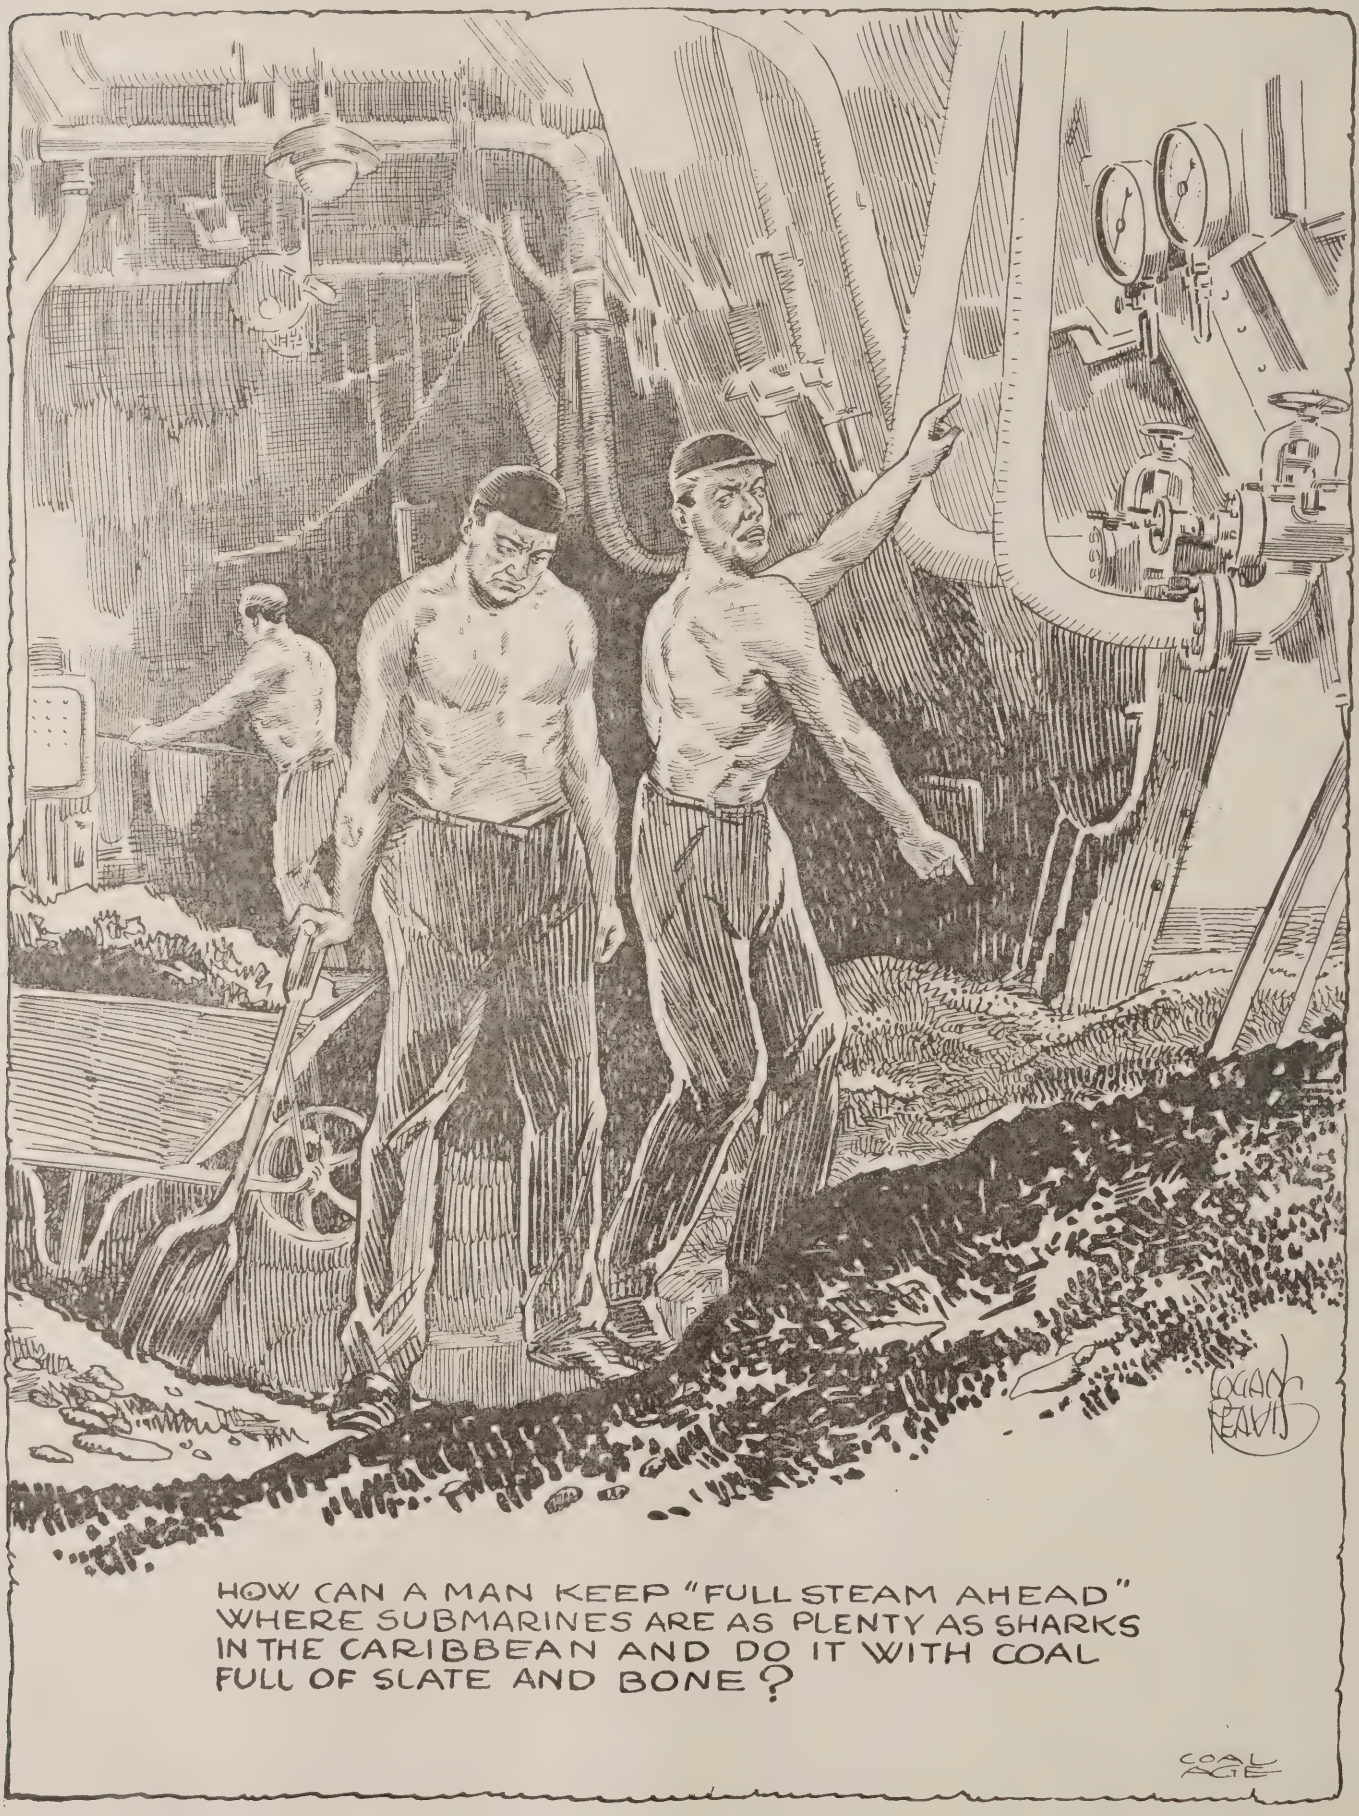
Lack of superintendence has broken many an industrial organization as lack of officers, commissioned and noncommissioned, has played havoc with many an army. The mining industry lacks officers. It gets along with a minimum of supervisors, and too many of those who do supervise are petty tyrants. They rule and make decisions without knowledge of conditions. They cannot get around the hundreds of places and see for themselves, and they lack the men who can. Let us get them out of this rut during the war. They are good fellows enough in their spare time; but at their work worry and the impossible demands made on them addle their brains, and in too many cases, we fear, unfit them for their positions.

Untrained Men Will Not Serve Our Ends

MOST of the industries have been content to take men in the rough and by putting them to work have endeavored to train them into industrial fitness, advancing them to places of importance according to the experience gained. The necessities of this war, however, could not wait on such slow processes of development. Every man was more or less a green hand in the game of war; defeat and perhaps death might have been the outcome of lack of experience, so it was necessary to accelerate the manifold processes by which the soldier's art was assimilated and take advantage of every facility.

The language question was tackled early. All the boys in the army will soon know how to understand their officers and how to report to them. All will know how to read a written order. These are elementary matters, but in mining we have not as yet reached them. Still the foreman goes from place to place and is met with "Me no forstay." Hurriedly an interpreter is summoned who may or may not correctly interpret the foreman's instructions. But the army is settling the matter fundamentally with the dictum, "Every man must know how to read and speak English."

But this is not enough. There are already 47,000 men being taught in army schools, and they will be turned out more or less completely trained at the rate of 23,000 a month. None of the colleges will operate this year except as military training schools, for the draft has wiped out all possibility of successful operation under civilian plans.



Those who enter college will be inducted into the army as privates, with a private's pay and subsistence, being under full military jurisdiction. Boys of 20 will stay in school three months, those of 19 six months, those of 18 one year. In all cases men who clearly show that they may make good officers or good technical experts may be detailed to take further instruction.

But besides these there are detachments of mechanicians under training. By Oct. 1, 90,000 men will be turned out, and the quota for the period between Oct. 1 and July 1 will be 220,000. Already 147 schools are engaged in this work, and 120 of them have been accepted for winter courses.

We are about to have a well-trained army. After the war we must have well-trained industrial workers. Not only the captains of industry, the managers, the engineers and the foremen must be trained, but the workingmen also must receive instruction. While there must be heads in every department of industry there is no greater need for the intelligent direction of industrial labor than for its intelligent performance.

The truth of this has been proved again and again. Our American engineers in foreign countries have repeatedly given up in despair the obtaining of a large output whenever the methods and mentality of the men in their employ militate against efficient operation. The industrial efficiency of the present day is only partly the result of our mechanical aids; it is at least equally the outcome of education and of the resultant psychological conditions.

Then Our Brave Ship's Stokers Lose Heart

DISCUSSION BY READERS

Scraper Mining in Low Seams

Letter No. 2—Kindly permit me to refer to the letter of John Lloyd, efficiency engineer, Lehigh Valley Coal Co., which appeared in *Coal Age*, Aug. 22, p. 371. The letter refers to the scraper system described by H. G. Davis, of the Lehigh & Wilkes-Barre Coal Co., in the issue of the same paper for July 20, p. 92.

Mr. Lloyd takes exception to the statement made by Mr. Davis, who refers to myself as being "the first to introduce this system in the coal mines." The exception taken by Mr. Lloyd is based on the fact that the Lehigh Valley Coal Co. had made experiments with scrapers, early in 1914, at the Seneca Colliery of that company. He refers to the fact that I did not enter the anthracite region until the fall of 1915, and seems to associate my interests in the scraper system for mining thin coal, with my employment, while general superintendent of the Delaware & Hudson Co., of a former employee of the Lehigh Valley Coal Co. Mr. Lloyd states that this man was acquainted with the experiments that had been conducted at the Seneca colliery and had sketches of the system there employed.

Allow me to say that, in making these statements, Mr. Lloyd does me an injustice that I feel sure he does not intend and of which he would not be guilty were he fully acquainted with the actual facts, which are as follows:

Experimental Development in D. & H. Mines

Shortly after entering the employ of the Delaware & Hudson Co., I was given the problem of mining the "Twenty-Inch Bed" by mechanical means. The company had purchased shortwall-mining machines and, upon the recommendation of our consulting engineer, Eli T. Connor, we tried out all the methods known to us for removing the coal from the face without taking rock for height. These methods were specifically mentioned in an exhaustive report, which Mr. Connor had made, at some time previous, covering this particular bed, and which included buggies, face conveyors and scrapers.

The buggies we already had, as the Delaware & Hudson Co. uses hundreds of them. These were immediately put to work and a longwall conveyor of the chain type was ordered. We knew, vaguely, of the use of a scraper by the Lehigh Valley Coal Co. and tried to get their permission to visit the mine where it was reported to be at work. Not succeeding in this, however, we started experimenting with scrapers of our own design. Our first scraper was built of plank bound with iron straps. It looked very much like a snowplow and was operated by means of a small two-drum electric engine. This scraper was awkward, but it did the work after a fashion.

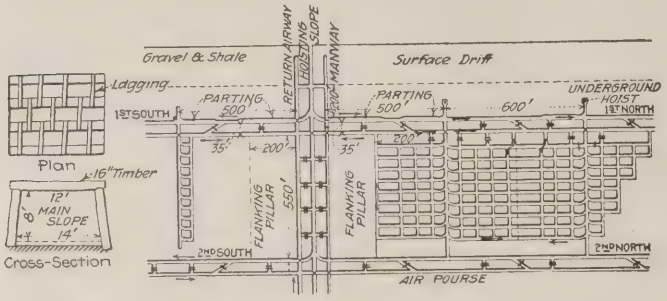
It is true that, in the course of these experiments, I employed a man as assistant who had been on the surveying corps of the Lehigh Valley Coal Co. and who had seen the scraper of which Mr. Lloyd speaks. But the man did not supply me with any sketches of it, and the knowledge that he brought to me concerning its operation was meager and had no bearing on our developments.

Subsequently, we built several other forms of steel scrapers and many different forms of snatch blocks and guides, for the purpose of controlling the scraper and causing it to load itself without the necessity of hand shoveling. Finally, we developed a method of control that caused the scraper, of itself, to dig out and move the undercut coal. It is the combination of devices that accomplishes this result and is covered by U. S. Patent 1,268,557, granted June 4, 1918.

The patent covers, in explicit terms, an improvement in the art of moving loose material and makes no claim whatever to a monopoly in the use of a scraper. It described specifically a method by which a scraper can be caused to load itself in a chamber and this is something that, to my knowledge, no other scraper system has been able to accomplish. The operation of the apparatus, as described in the patent, is radically different from that used in the mines of the Lehigh Valley Coal Co. which is described in the *Employees' Magazine* of that company for April, 1916.

The patents have been passed upon by a number of eminent patent authorities and licenses to manufacture the "Evans Scraper Loading Apparatus" have been granted to the Engineering Development Co. of Scranton; the Cook-Wilson Electric Supply Co. of Pittsburgh and the Goodman Manufacturing Co. of Chicago. The Delaware & Hudson Co. has 35 of these patented scraper systems at work, and nearly 60 additional sets of apparatus are under manufacture. The Pennsylvania Coal and Coke Corporation of Cresson, Penn., has about 12 sets of apparatus at work and 50 more under construction. The patented device is a proved success and while other scrapers are in use, they seem to be still in the experimental stage.

Retsof, N. Y. CADWALLADER EVANS, JR.



Working 10-Ft. Inclined Seam

Letter No. 6—An experience of a number of years, in pitching and flat seams, both in the United States and Canada, caused me to be deeply interested in the several letters published in *Coal Age*, in reply to the inquiry of "Superintendent," Mar. 23 p. 561. The proposition presented, namely, the working of a 10-ft. seam pitching from 10 to 15 deg., will appeal to most practical mining men as involving many important features in coal mining.

The plan I would suggest in the development of this seam is shown in the accompanying figure. The main slopes should be driven three abreast, on the full dip

of the seam, and cross-entries turned to the right and left, at distances of 200 yd. apart, center to center. These three main slopes consist of a hoistway or haulage road, a main return airway and a manway. Each pair of cross-entries is composed of a haulage road and air-course. As shown in the detail sketch, in the figure, the main slope is 14 ft. wide, in the clear, at the bottom of the road, and 12 ft. between notches on the collar, and has a headroom of 8 ft. The timber frames are set 4 ft., center to center, and the lagging above the collar is staggered, as shown in the sketch. This will afford a good support for the soft, sandy, shale roof.

The general plan of working is to drive butt headings to the dip or the rise of the cross-entries and turn rooms to the right and left of each pair of butts. The

SHOWING PLAN OF WORKING AND DETAIL OF TIMBERING THE AIRWAYS

butt headings are driven 600 ft. apart, so as to provide for rooms 300 ft. in length, which are turned on 50-ft. centers and driven to meet each other. In the figure, I have shown the butt headings as driven to the dip, the purpose being to yield quicker returns in the extraction of the coal, although this will require installing a compressed-air hoist at the head of each butt, to haul the coal up to the level.

Storage-battery locomotives should be employed on the levels and rope haulage on the main slope. Many will prefer to drive the butt headings to the rise, so that the coal from the rooms can be lowered to the level, which plan will also take care of the drainage from the rooms. In any case, the first pair of cross-entries must be turned at such a distance from the mouth of the slope as to provide a solid barrier of coal, 15 ft. in width, above the workings. This will prevent any undue inflow of water from the surface into the mine, during a rainy period.

Method of Working and Ventilating the Mine

As shown in the figure, the first pair of butt headings should be driven at a distance of 500 ft. from the main slope, which will provide a solid pillar of coal, 200 ft. wide, flanking the main slope and allow for rooms, 300 ft. deep, to be driven off the first butt heading. The general plan of the ventilation is indicated by the arrows in the figure, the main slope and haulage roads being made the intake.

In driving the rooms, I would use a shearing machine to shear the coal 6 or 7 ft. deep on the low side, which would give a loose end to shoot and materially increase the percentage of lump coal. The same method should be used in driving the cross-entries, but in driving the slopes or butts to the dip, the shearing cut should be made in the center of the breast and the coal shot from each side toward the center.

The slope track should be laid with 45-lb. rails and the same should be used in the cross-entries, while 30-lb. rails can be used on the butt headings driven to the rise or dip and 20-lb. rails in the rooms. The track ties on the main roads should have at least a 6-in. face and be spaced not more than 2 ft. apart, center to center. In the rooms, smaller ties can be used, spaced 3 ft. apart, center to center. All rail joints should be provided with fishplates. I much prefer the use of the "tumble switch" or ground-throw type, which reduces the chance of men falling over switch stands. When properly installed, the tumble switch is just as efficient and handled as easily as any other type. For drainage, good ditches should be provided on the low side of the road, as the condition of the track will depend much on its being kept dry and well ballasted.

Guarding Against Surface Disturbances

The inquiry states that the surface is traversed by numerous large streams and that the seam is subject to many irregularities and faults or "pitchouts," To avoid trouble, on this account, large pillars should be left to protect the surface at such points and only entries and air-courses driven through them. These should be strongly timbered or concreted where water seeps through the roof. My experience suggests that it would be well to prospect such places by drillholes, to ascertain the actual thickness of the rock overlying the coal.

When mining in Alberta, some years ago, we ran into the bed of the "Old Man River," although the entry we were driving was supposed to be 500 ft. below the surface. We had kept drillholes ahead in the coal, and the face of the entry was 200 ft. ahead of where the water broke in. It was found, later, that the strata had been eroded to within 18 in. of the coal, at the point where the break occurred. The hole was not more than 2 ft. in diameter and must have been the bottom of a pothole, which extended to the river bed on the surface. Such occurrences cannot be said to be uncommon in coal mining, and every precaution should be taken to avoid disaster when working under such conditions.

Cassidy, B. C., Canada. J. W. Powell.

Hindrances to Coal Production

Letter No. 2—With increasing interest I have read the numerous articles, appearing from time to time in *Coal Age*, relating to the production of coal and its hindrances. The subject is of vital importance, particularly at this time when the nation is facing the necessity of supplying the abnormal demand growing out of war-time manufacturing and the increased activities of the Navy.

England is now facing a coal shortage and hundreds of her ships that, in former years, sailed for South America laden with coal, now sail in ballast. The result is that our sister country, lying to the south, is looking to us for fuel. In our own ports, a multitude of bottoms used in the export of coal are idly waiting for their cargo.

Let me ask, What are the factors that hinder the production of coal? Is it a single factor; is it the miner; or is the operator to blame? Volumes have

been written on the car shortage and hundreds of complaints have been hurled at the railroads; but the situation in that respect has greatly improved and, today, observation in the coal regions shows that the car supply at the mines is now rarely to blame for the mine not running to its full capacity. My belief is that a large percentage of mines fail to load their allotment of cars, day after day.

Reasons for Low Tonnage Production

Look now at the miner, and we find that the weigh-sheet on any tipple shows that while some men load 15, 18 and even 20 tons of coal a day, the same sheet records but 6, 8 and 10 tons for other men. Following up these numbers, it is seen that their low tonnage is nothing unusual but a daily occurrence. Practical mining men know that there are many reasons for this great variation in tonnage among the men. There are, of course, some slackers who spend their time visiting other places and talking instead of working. There are others that are working under unfavorable conditions, bad roof, water at the face, or the coal is not cut regularly, etc.

A more important reason for low tonnage, however, is one for which the miner is not to blame, but the company who often fail to provide adequate equipment. There is an insufficient supply of mine cars, mules or gathering motors; or the haulage system is not sufficient to haul all the coal to the tipple as it is mined. In some cases, preference is given, in car distribution, to places that the company is desirous of developing more rapidly, with the result that the miners in other places are short of cars and must wait.

It is true there is a labor shortage at many mines, but it cannot be denied that days when the car supply is ample many mines fail to produce a fair average tonnage for the men that are actually on the job. There are notable exceptions to this, but failures are sufficiently numerous to establish the rule.

Summarizing the Situation

By way of summing up the situation, let me say that there are, to my mind, three factors to be considered, each of which must be brought to the highest point of efficiency, in order to secure a maximum coal production. There is no question that the large majority of coal operators are most loyal to American principles and ideals. The same is true of the large majority of miners who are among the most loyal of American citizens.

However, among the operators and the miners, alike, there are some who are not loyal. There are operators who fail to provide the most up-to-date or even adequate equipment for the working of their mines to full capacity. There are miners who do not devote the entire working day to the getting out of coal.

Of the railroads, it may be said that, notwithstanding the immeasurable improvements made under the Railroad Administration, the work can still be speeded up and the car supply made better and more constant. The Administration will, I believe, put forth every effort to do this. By accelerating the movement of coal trains, both loaded and empty, and equalizing the distribution of cars, the railroads will put the responsibility for coal production up to the operators. Again, by improving their equipment and systematizing the work underground, the operators will shift the burden of responsibility onto the miners, who must see to it that there are no 6- or 8-ton days to their credit when the conditions are such that a man can load 12, 15 or 20 tons in a single shift.

In closing, permit me to say, let there be less of "passing the buck." Let the operator, the miner and the railroads look to their own share of the work, shoulder their own responsibilities and be less disposed to lay the blame on the other fellow when the fault is their own. The carrying out of this program would result in a production of coal that would far surpass the wildest dreams, and our boys "over there" would know that their comrades "over here" are behind them, while the world would look to us with joy, as coal producers and not buck passers, and there would be no coal shortage the coming winter. Observer.

Huntington, W. Va.

The Miner and His Pleasure

Letter No. 3—I read with much pleasure the two letters on this subject, written by Thomas Hogarth and Joseph R. Thomas, which appeared in *Coal Age*, Aug. 15, p. 329, and Sept. 5, p. 463, respectively. Like them, I feel that if any man living is entitled to pleasure, it is the coal miner. He is the only workman under the sun who must perform his work in darkness shut out from the light of day. For this reason alone, he should be permitted to enjoy himself in his spare hours.

For the past seven years, I have been foreman of mines and have seen many of the difficulties connected with mining. Like Mr. Thomas, who compares conditions in two mining camps that are as different from each other as light from darkness, I would like to draw a similar comparison between two thriving mining towns or camps in Indiana County, Pennsylvania.

In the first of these towns, the miners were privileged to own their own homes where they lived and brought up their children. The company who employed them gave them every encouragement in this direction. They supplied everything in the way of sports and recreation that the miner could ask. There were baseball, football and basketball teams. There were also provided a good theater, dance hall and lodge rooms. The town was kept clean and healthy; there were good roads well drained, and sidewalks. This place never knew what scarcity of labor was, because it got skilled workmen; and when these moved in, they stayed, some of them for life.

A Striking Contrast

As a contrast to this condition so favorable to the miner, let me describe another town in the same county. This was a company town. Everything was owned and operated by the company wholly in their own interests. No one could buy enough ground to erect a chicken coop. The miners worked early and late and there were no sports or pastimes to while away the idle hours. It is not surprising that a lower grade of men were attracted to this mine, and that the saloon was the chief resort when the men were out of the mine. When labor became scarce, this place was the hardest

hit of any town in Indiana County and it is easy to imagine why.

Before closing, I want to mention another town where everything is provided in the line of amusement and recreation that could be desired, and yet men are very scarce. Even those who are there do not work steadily, for some reason or other; perhaps someone can tell. The men have every convenience at home, fairly good working conditions and everything to make life worth the living. Still, few of the men work steadily.

For the purpose of showing the loss to this place and to the coal industry, owing to unsteady work, I will quote a few figures showing the number of days worked and the number of days idle during the months of June and July, in one of Johnstown's largest mines.

	Days Worked	Days Idle
Section 1	5,410	590
" 2	2,100	200
" 3	3,775	327
" 4	6,235	735
" 5	3,972	403
	21,492	2,255

The table shows a loss of 2255 working days out of a total of 23,747 possible workdays, which is one idle day out of every 10½ days that the men should have been at work. As these men average 4½ tons of coal per man, the idle time means a loss of 10,147 tons of coal in two months. I hope that someone will be able to suggest how to overcome such conditions, which are a menace to the safe prosecution of the war.

Johnstown, Penn. FAIRPLAY.

Americanizing the Foreigner

Letter No. 4—I read with interest the observations of "Experience," on the subject of Americanizing the foreigner, *Coal Age*, Aug. 8, p. 286. He sizes the situation up as a hopeless one; but it is my belief that, in the last few years, much progress has been made in raising the social standard of the foreigner employed in this country. Why should it be a hopeless task to engender American ideas into these foreign workers. The same might be claimed in respect to a large number of our own people who need to be Americanized as much, in some cases, as the foreigner.

Of course, nearly all of us are prone to resent any radical change in our lives and habits, and we refuse the guiding hand that would assume to bring about such changes. Nevertheless, every day makes it more and more evident that the foreign classes employed in our mining districts are slowly but surely becoming Americanized and possessed of higher ideals than were theirs in the old country.

What Are American Standards?

Before going further, let me ask, What constitutes Americanizing the foreigner. It may be impossible for him to speak our language fluently. The foreign-born American, even though bred in England, can hardly assume to give the same inflection and speak with the same fluency as the American born.

What then? Is the standard to be set by the number of automobiles, player pianos, talking machines or similar evidences of wealth on the part of their owners? In this respect, the foreigner is certainly keeping pace with the Americans.

Again, in respect to patriotism and loyalty, we find that the foreigner is a heavy investor in Liberty Bonds and War Savings Stamps, which is an evidence of their thrift; while it cannot be said that thrift is the characteristic of the majority of Americans. But, no one will deny that, at the present time, the most American and patriotic thing to do is to exercise thrift, notwithstanding so many Americans are failing in this respect.

Mention has been made of the foreigner's habit of raising hogs in the cellar, stabling cows under the house or keeping chickens in the same house in which the family lives. It should not be a difficult matter for the management of a company to set their foot firmly down on these sort of practices and segregate the human from that which is purely animal. There are, moreover, instances where the American born have been found just as lax in the sanitation of his dwelling as the foreigner.

The Foreigner and the Liquor Question

In my opinion, booze and the overcrowding of boarding houses are as responsible as anything else for the slow social progress of the foreigner. Where his appetite for intoxicating drinks is allowed to run unchecked, he has neither time, money or inclination for improving his social condition. Prohibition and bone-dry laws do not frighten him; for where he is able to procure sugar there are a thousand and one ways in which he can brew his drink and the result is just as effective and potent as the alcoholic drinks that prohibition has outlawed.

The foreigner is very resourceful in manufacturing his own drinks and some of these are brewed and fermented in an incredibly short time. Those people are known to brew a beverage from raisins, sugar, cornmeal and rain water, which is allowed to ferment nine days and the result is what is called by them "Old Hen," because of the short time it is required to "set."

Use of Sugar To Make Intoxicating Drink

So long as unscrupulous and unpatriotic merchants are permitted to sell these foreigners large quantities of sugar, they will continue to make their own drinks. Whether sugar necessarily enters the composition of all intoxicating drinks matters not, but it is a quick ferment and this misuse of sugar by the foreigner works an unnecessary hardship on the American who is restricted to two pounds a month for his individual use.

Another un-American mode of life is the typical foreign boarding house. A dwelling intended to wholesomely accommodate a family of four, five or six, is sometimes assumed to have double or even treble that capacity to hold foreign boarders. Such an overcrowded condition cannot fail to breed sickness, drunkenness and discontent.

It would seem that such a condition, also, could be remedied by the establishment of club boarding houses. It might not be possible for a boarding house boss to realize the same profit, and let me say here that the boarding boss in most instances is a very important personage of leisure and will compare well with the feudal landlord of the old country. But, the establishment of a club boarding house operated and controlled by the company would develop better citizenship.

Thomas, W. Va. W. H. NOONE.

INQUIRIES OF GENERAL INTEREST

Estimating Power in Haulage

I am anxious to ascertain the general method of determining the horsepower of a mine motor capable of hauling trips of 25 cars under the following conditions: Length of haul from inside parting to tipple, 3000 ft.; maximum grade, 2 per cent., against the loads; weight of empty car 1200 lb.; capacity, 3200 lb. of coal. The required output is 1000 tons a day of 8 hr. All supplies, rock and refuse to be handled on the night shift.

———, Ill. MINE ENGINEER.

It is necessary to first estimate the weight of loaded trip, track and grade resistance, required weight of motor, assuming a tractive effort of, say one-sixth of the weight on the drivers and the efficiency of motors as 90 per cent. The required power is then determined by the product of the tractive effort, speed of hauling and efficiency of the motors. Thus,

Weight of loaded trip

$$25\ (3200 + 1200) \div 2000 = 40 \text{ tons.}$$

Assume roller-bearing cars, track resistance 20 lb. per ton, grade resistance for 2 per cent. grade being 40 lb. per ton, total resistance of moving trip is 20 + 40 = 60 lb. per ton.

Now, call weight of locomotive resting on drivers W_m, in tons, the tractive effort is $\frac{1}{16}$ $(2000\ W_m)$ = say 320 W_m. The weight of trip and motor is $(W_m + 40)$, in tons. Then, since the tractive effort of the locomotive must, at least, be equal to the entire resistance of moving trip and motor

$$320\ W_m = 60\ (W_m + 40); \text{ and } W_m = \frac{60 \times 40}{320 - 60}$$

$$= 9 +, \text{ say } 10 \text{ tons.}$$

Number of round trips, in 8-hr. day, $1000 \div 40 = 25$; time required per trip $(8 \times 60) \div 25 = 19.2$ min. Allowing time for change of trip, assume actual time of hauling is 12 min., which gives for speed of hauling $(2 \times 3000) \div 12 = 500$ ft. per min.

$$\text{Power required } \frac{10 \times 320 \times 500}{0.90 \times 33{,}000} = 53.87, \text{ say } 60 \text{ hp.}$$

Iron vs. Wood Mine Cars

I very much desire to learn the general opinion of practical mining men in regard to the relative advantages of iron and wood for the construction of mine cars, and to ascertain which of these two types of cars is generally preferable.

In mining, as in other industries, the use of iron is rapidly superseding that of wood for many purposes; but, for some reason, iron mine cars have not been generally adopted. The reason for this must lie in the fact that they have not been found wholly adapted to the haulage of coal underground. It cannot be assumed that mining engineers, who have been so quick to recognize the great advantage in the use of cement in mining work, prefer to build wood mine cars instead of iron, without having good reasons for their choice.

It is true that wood is cheaper than iron, but it should be remembered that when worn with use what remains must be thrown aside as having no value. On the other hand, old iron thrown on the scrap heap still has a value, as it can be smelted and used again. Thus, the value of scrap iron helps to balance the increased cost of the original material over wood.

Notwithstanding the fact that iron is stronger than wood, in the ratio of about 10: 1, the weight of iron cars is much greater than that of wooden ones of equal capacity; and it cannot be denied that this feature, alone, is an important item in the handling of cars in the mine, both at the working face and on steep grades on haulage roads. A derailed iron car is far more difficult to replace on the tracks than a wooden one. Also, the ratio of dead to live loads is greater when hauling a trip of iron cars than where the cars are made of wood.

To balance these disadvantages, let me suggest that the longer life of iron cars will go far to offset the expense of maintenance of wooden ones. Also, manufacturers of iron mine cars are giving much attention to improve their designs and reduce the weight, for the same capacity of car, so that the question of greater weight is not now as important a feature as formerly. The fact that it will cost more to restore a badly damaged iron car than to repair a wooden one is a matter requiring the attention of mine officials, since the damage to cars is largely the result of unnecessarily rough usage; failure to maintain good tracks; and the employment of incompetent motormen.

I hope to see this question thoroughly discussed, with a view to ascertain what has been the experience of mine officials who have used iron cars in their mines. In stating the results in practice, we should be careful to name the conditions existing in the mines and affecting the haulage of coal, in order to arrive at an intelligent comparison that will be of value.

Wylam, Ala. GEORGE HUSBAND.

Coal Age is glad to second the suggestion of this correspondent and to ask for an expression of views, from its practical readers, in regard to the relative utility of iron and wood cars, in coal-mining practice. As shown in this inquiry, there are arguments for and against the use of iron cars in coal mining. There are mines operating with iron cars and getting good results from their use; and no one understands better the resulting advantages and disadvantages than the mine foreman who has had to overcome the difficulties presented, in order to benefit by the change.

The suggestion of our correspondent that the conditions surrounding the use of cars in the mine should always be described is an important one. Iron cars may prove advantageous in one mine and an utter failure in another.

EXAMINATION QUESTIONS

West Virginia Examination (1918), Mine Foremen and Firebosses

(Selected Questions)

Ques.—What is ventilation, and why is it necessary in coal mines?

Ans.—The ventilation of a mine requires the maintaining of a sufficient quantity of air, in circulation throughout the workings, to keep them in a healthful and safe condition. For that purpose, the air current must be conducted through the several passages of the mine, and made to sweep the working faces and all void and abandoned places where gas will accumulate. The ventilation of a mine is necessary in order to insure the safety and health of the workmen employed underground, and prevent the damage or destruction that would result if gases were allowed to accumulate and an explosion should take place.

Ques.—Explain the safest and most effective way of circulating air through mines.

Ans.—The means employed to circulate air currents in mines should be independent of natural conditions in the atmosphere. In other words, reliance should not be placed on natural ventilation, which is dependent on the difference of temperature in the upcast and downcast shafts, or the pressure of surface winds, or the fall of water in a shaft. Likewise, dependence should not be placed on furnace ventilation, which would be unsafe should the generation of gas in the mine develop. The safest and most effective means of ventilation, in mining practice, is a centrifugal fan of sufficient capacity to pass a required quantity of air, against a water gage not exceeding 2 inches.

Ques.—Is it safe to pass a current of intake air through the abandoned portions of a mine and then conduct it to the faces of the workings? State your reasons.

Ans.—Such a practice would be very unsafe. An air current that has passed through abandoned workings should be conducted directly into the return airway and carried out of the mine, without being permitted to enter any of the workings, because of the danger that it has absorbed poisonous or inflammable or explosive gases, which would render the working places either unhealthy or unsafe for work. The men might be overcome by breathing noxious gases, or an explosion might occur from gas being ignited on any one of their lamps.

Ques.—What are the legal requirements regarding old and abandoned workings, mine maps and second openings?

Ans.—The mining law of West Virginia (Sec. 27) requires all abandoned parts of mines to be safeguarded in a manner that will prevent, as far as practicable, the accumulation of gas therein and the entrance of persons unwarned.

Sec. 15 requires the operator or agent of every coal mine to provide an accurate map of the mine, drawn to a scale of 100, 200 or 300 ft. to the inch. The map must show all openings, shafts, slopes, entries and airways, and the direction of the air currents must be indicated by arrows. All rooms, pillars and abandoned workings must be accurately shown on the map, together with the property lines and outcroppings of the coal, within a thousand feet of any part of the workings of the mine.

A true copy of the map must be sent to the mine inspector of the district, to be kept in his office for reference, but not to be copied by anyone without the consent of the owner or operator of the mine. A copy of the map must also be kept at the office of the mine and available, at all reasonable times, for the examination of the inspector. The law requires the surveying of the mine twice each year and the extension of the map in accordance with such surveys. The map must contain the certificate of the engineer, acknowledged by a notary or justice of the peace.

Sec. 31 forbids anyone to work in a mine, unless it has at least two openings or outlets in each seam, such openings to be not less than 300 ft. apart, in the case of shafts, and not less than 50 ft. apart, in the case of slopes or drifts. This law applies to all shaft openings made subsequent to the passage of the act. Each opening must be reached by an available roadway that is well drained and kept free of any obstruction that would prevent the travel of men, in case of necessity. Each opening must be fitted with stairs or hoisting machinery, which must be kept in order ready for immediate use when required. In addition to the regular hoisting apparatus, the hoisting shaft must be equipped with an emergency windlass or other hoisting device of ample strength for hoisting men, as aproved by the Department of Mines.

Ques.—What would be the minimum amount of air required in a split where 60 persons and 10 mules are employed?

Ans.—The state mining law (Sec. 17) requires the circulation of at least 100 cu.ft. of air per min., for each person employed in the mine, and as much more as the district mine inspector may require. No mention is made of the amount of air required for the mules; but the inspector may follow the practice in other states, which requires 500 or 600 cu.ft. per min., for each mule underground. In that case, assuming that the mine is generating no gas, the quantity of air required for 60 persons and 10 mules would be $60 \times 100 + 10 \times 500 = 11{,}000$ cu.ft. per minute.

Sec. 26 of the law requires the circulation of 150 cu.ft. per min., for each man employed in a mine generating gas or where gas may be expected in the future development of the mine. In that case, the quantity of air required, in the same instance, would be $60 \times 150 + 10 \times 600 = 15{,}000$ cu.ft. per minute.

COAL AND COKE NEWS

Harrisburg, Penn.

The production in the Pittsburgh district of a considerable quantity of dirty coal is causing the Fuel Administration to condemn several carloads of such coal weekly. When condemned the fuel must be sold at 50c. per ton less than the prices fixed by the Government. Much of the dirty coal, it is said, is being produced from wagon mines and stripping operations. The coal from the stripping mine, it is claimed, has been taken from too close to the surface to be of much heat value, and it is contended it is useless to waste freight cars in hauling it.

Fuel administrators are urging upon operators, dealers and consumers of coal the necessity of unloading coal from cars promptly. Operators are urged to place upon coal cars at the time of loading such warnings as the following: "Unload this car of coal promptly if you want it returned to you promptly." "The miners are waiting for this car. Unload it quickly." The notices state that it is not so much the shortage of cars that is causing a shortage of coal as it is the tying up of cars by receivers of coal failing to unload the coal from the cars promptly.

T. Ellsworth Davies, consulting mining engineer of Lackawanna County, has been employed by the County Commissioners to make a survey of coal lands in Dauphin County. He will do this with a view of establishing more just assessments for taxation purposes. Mr. Davies will begin the survey with a corps of assistants and an office force and will make monthly reports to the commissioners. The survey will include a physical examination of the coal deposits and Mr. Davies expects to produce data which will warrant a great increase over the present assessment rates in the upper part of the county.

Uniontown, Penn.

By direction of Fuel Administrator H. A. Garfield, the salvaging of coke screenings from abandoned ash dumps was discontinued Monday, Sept. 16. While the order sets forth that the action was taken because "there is a shortage of labor in the beehive coke district and that the labor employed in reclaiming old breeze dumps at beehive coke plants can be more effectively employed in the production of coke needed in the war industries, and that the elimination of this work will appreciably relieve the over-burdened railroad transportation facilities," local operators see in the order another result of the recent coke inspection system established with R. C. Glazier as its chief.

The coke breeze industry in the Connellsville region had reached such proportions that it demanded an average of 15 cars daily. It has grown so rapidly since the present fuel emergency that some time ago it was recognized by the fuel administration as a byproduct of the coke region with the fixing of basic prices ranging from $7.30 for the highest quality down to $3 per ton for ordinary coke breeze.

With the official banning order it became known that for some time past an investigation has been in progress to determine the facts as regards the quality of the breeze shipped from the region. Operators who from the start did not favor the working over of the ash dumps claimed that its theory of conservation and turning a liability into an asset was its principal argument. They claim that it has not met the acid test of practical application for the reason that it may be assumed that coke operators conduct some supervision over their dumps to cut down the fuel wastage.

Charleston, W. Va.

Cars in the Fairmont district were somewhat more plentiful this week and last week than was the case at the beginning of September, but it is still contended by operators that much of the supply exists principally on paper and that figures given out do not really represent the actual supply. In fact production committees assert that the supply is still insufficient insofar as enabling the mines to make any record in loading coal. However, it is so much better on the average than it has been that coal men are hopeful that within a few weeks the highwater mark of July may be reached. As indicated in last week's correspondence, no difficulty was experienced by the mines in Randolph County which are supplied by the Western Maryland, but much of the fuel shipped on that road is for railroad use. Late placing of cars continues to restrict the output in the Fairmont region.

Little complaint is heard from the Guyan and Kenova-Thacker districts, where the transportation facilities are nearly up to the requirements of the mines, a 100 per cent. car supply having been promised by the railroads. Mines in the Guyan region are supplied principally by the Chesapeake & Ohio Ry., and that road has succeeded in improving its supply for the New River and Winding Gulf regions as well as in the Guyan region.

There has been a material increase in the total net tons of coal produced in the Pocohontas and Tug River districts during the past week over the week previous. The number of hours lost owing to car shortage was reduced from 678 to 110. The tons lost because of car shortage amount to only 10,469. Last week the car shortage caused operators to feel apprehensive, but the improvement has brought a good deal of encouragement. With more cars on hand and with the number of hours worked increased by 246, production went forward and at the same time the total tonnage lost was reduced by 37,264 tons. The total tonnage produced was 438,524, requiring 7217 working hours. From all causes 55,573 tons were lost due to all causes. Labor shortage was responsible for the loss of 39,858 tons. Production committees in the Tug River and Pocahontas districts feel that the output can be materially increased and every effort is being directed to that end. Coke output in the districts named shows an upward trend, the production being 49,129 tons.

In the Kanawha coal fields there has been a steady increase in production since the close of August. A large gain was made even with Labor Day lost, or virtually lost, and since that date there has been a steady increase in production, made possible by approximately a 100 per cent. car supply. Like conditions prevail in the New River and Winding Gulf Districts, where with improved transportation facilities the mines have been able to produce much more coal. Results have also been achieved in these two districts through an elaborate production organization. As car supply and increased effort on the part of the miners go hand in hand, and as this has been pretty well worked out in the New River and Winding Gulf sections, the increase in output has been most marked.

Birmingham, Ala.

Lagging output is still reported by the coal mines of the Birmingham District, caused mainly by the inability of the railroads to give all the service asked for. Labor is not so efficient as it might be, as many employees of the mines do not apply as much time as they might to their tasks. There is belief, however, that when the Warrior River barge line is placed in operation, which is promised by M. J. Sanders, director of the transportation system, within two weeks some relief will be afforded the railroads in the coal-mining sections, especially in the western part of Jefferson County, and near the edge of Walker. The cars released by the placing in operation of the Warrior barge line will be used in other directions.

Coal production in Alabama for the week ending Sept. 7 showed some improvement over the previous week, the output being 382,939 tons compared with 390,412 tons for the last week in August. For the week ending Sept. 14, figures for which are not yet complete, it is believed the 400,000 mark has been passed, on the face of available reports, though the loss of production at Lewisburg is being felt, and rail service has not been normal during the past week. To bring production up to last year's figures it will be necessary for the mines to record an output of 420,000 tons or more per week.

Victoria, B. C.

Sixteen miners lost their lives on the morning of Tuesday, Sept. 10, when the cage in which they were descending the Protection Island shaft of the Canadian Western Fuel Co.'s mine, at Nanaimo, B. C., became detached from its cable and fell a distance of approximately 300 ft. The cage had raised all the men of the night shift to the surface and carried six loads of 16 down when the accident happened. It had scarcely left on its seventh trip when the cable parted, the miners still waiting their turn being informed of what had taken place by seeing the parted cable, released of its load, swinging loose in the shaft. Subsequently it developed that the safety locks had failed to act and that the cage had struck the loading landing, constructed of 12-in. timbers, with such force that it went through, finally resting 50 ft. lower on an abandoned level not used since the upper seam was opened some years ago. This is the most serious coal mine disaster that has occurred in British Columbia since early in the month of April, 1917, when 34 miners lost their lives in an explosion at the Coal Creek Mines, Crows Nest Pass Colliery, Fernie, B. C. Hon. William Sloan, minister of mines, has promised that the fullest investigation will be made in order that the responsibility may be fixed.

Elmonton, Alta.

An active campaign is in progress to induce coal dealers and consumers to use Alberta coal instead of withholding orders in the expectation of being able to procure anthracite. A statement is published by John T. Stirling, chief inspector of mines for Alberta, showing that the demands of the Western Provinces could easily be supplied by Alberta provided the orders were forthcoming. The amount of coal produced in that province in 1917 was 4,863,414 tons, exceeding the output of 1916 by 214,810 tons, notwithstanding labor troubles and lack of transportation facilities. If the mines had worked steadily throughout the year, with the present labor employed, the amount produced would have been approximately 8,000,000 tons, or more than 3,000,000 tons more than the amount actually produced. Over 3,000,000 tons imported from the United States are annually consumed in Manitoba and Saskatchewan, which should be entirely supplied from the production of Alberta mines, which could also supply a portion of the United States immediately south of the border.

The statement has been made that Alberta coal will not store, which while it may be true to a certain extent as regards 25 or 30 per cent. of the output, is not true of the other 70 or 75 per cent. Mr. Stirling says it is not reasonable to expect that while the United States is shutting down her industries to a minimum she will continue to supply coal to Western Canada when there is a supply at hand more than sufficient to cover all demands. It is not to be expected that American manufacturers will submit quietly to coal being exported to Canada, while their own industries are idle for days at a time for lack of fuel. The greatest demand comes in the fall and winter, at a time when the difficulties of operation are greatest owing to scarcity of labor and lack of railway facilities. In January, 1917, 8550 men were employed in connection with mining in Alberta. While in June the number was reduced to 3091 and again increased to 9812 in December, while overhead charges ran on just the same, causing a considerable loss. No industry can be built up in this manner on a permanent basis and it remains for some authority to institute some system to utilize the enormous force now going to waste.

PENNSYLVANIA

Anthracite

Mahanoy City—Officials of the Lehigh Valley Railroad Co. have received orders to make a canvass of every industrial plant in the region and urge owners to store coal for next winter as a matter of self-protection.

Hazleton—Under the increased demand for coal, and with prospects of receiving another wage advance, more men are applying for certificates as qualified miners than has been the case in many years. The examiners report a large increase in the number taking tests.

Georgetown—Carpenters of the Lehigh & Wilkes-Barre Coal Co., under the direction of Harry Mason, are contributing several hundred dollars' worth of work necessary to alterations of cupboards and equipment of the Red Cross workrooms. Several lumber firms have donated the lumber and the coal company men are doing this work at night after completing their day's work in the mines.

Wilkes Barre—In order to increase the output of coal and to stop illegal selling of liquor on Sunday, which, he contends is keeping miners from reporting for work on Monday mornings, A. C. Campbell, fuel administrator for Luzerne County, has filed proceedings in court to have the licenses of saloon dealers in Wilkes-Barre, West Wyoming, Plymouth and Exeter revoked. In all nine saloons have been attacked.

Upper Lehigh—M. S. Kemmerer, president of the Sandy Run Coal Co. and Upper Lehigh Coal Co., has offered the Government his mansion and the large Upper Lehigh Hotel for a hospital for wounded and convalescent soldiers. The Kemmerer property has probably the most elaborate gardens of any dwelling in the coal region. Thousands of dollars are spent annually in keeping them in shape and expensive shrubbery was imported from China, Japan and the Himalayas. Years ago Upper Lehigh's hotel was a health resort and was the scene of many social fetes.

Hazleton—Copies of the proclamation of President Wilson calling upon miners to accept deferred classification and maintain coal production were posted at all the Lehigh Valley Coal Co. collieries on Sept. 16. The loss due to enlistments in coal-mining towns was shown when Andrew Skurko was called to the colors from Beaver Brook, making the fiftieth boy who has been called out of a population of 650 persons. This is one out of every 13 residents. Sandy Run miners who tied up the mines there when their demands for transportation was refused are moving to other anthracite operations, but the colliery is working shorthanded.

Pittston—The court has sustained the claim of Dora A. Coleman and others against the Reliance Coal Co., and a rule for judgment on ejectment proceedings was sustained. The suit arose over a coal lease made by the late Isaac B. Felts to Theodore Hogan in 1906. The latter assigned his interest to the Reliance Coal Co. The lease provided for a minimum monthly royalty of $700 and the plaintiffs allege that no rent or royalty was ever paid since May, 1907. The defense was that faults were found which prevented mining, and Mr. Felts, before his death, had agreed to provide a suitable surface area from which the coal could be removed, but this was never done. The court holds that the coal company was lax in not endeavoring to remove the coal within a period of 11 years.

Bituminous

Pittsburgh—On Sept. 12 the portion of the tipple of the Ella mine of the United Coal Corporation spanning the two main tracks of the Pittsburgh & Lake Erie R. R. collapsed and fell, putting the mine out of business. A new tipple had already been planned parallel to the old one, most of the material was on the ground and part of the foundations built. A large force was immediately assembled and the erection of the new tipple started, and by Sept. 19 the railroad loading portion was sufficiently near completion to begin loading coal. The structure and conveyor for loading on the Monongahela River will be completed in about 45 days. The conveying machinery will be furnished and installed by the Roberts & Shaefer Co. of Chicago, Ill. No one was seriously injured in the collapse, though three of the tipple men fell with the span. The checkweighman had a narrow escape, however, and it took an hour and a half to dig him out of the wreckage; and then it was necessary to amputate his two wooden legs to extricate him.
